Introduction

The company Bayer CropScience AG is submitting a dossier for the re-approval of the microorganism Purpureocillium lilacinum 251 as an active substance under regulation (EC) 1107/2009.

The Microbial Pest Control Agent Paecilomyces lilacinus strain 251 was included into Annex I of Directive 91/414/EEC on 01/08/2008 (Commission Directive 2008/44/EC) and then approved according to the Commission Implementing Regulation (EU) No 540/2011 of 25 May 2011, implementing Regulation (E05) No 1107/2009 of the European Parliament 1). P. lilacinus strain 251 was withfied and defended by Prophyta GmbH. The active ingredient has been evaluated in Belgium according to Uniform Principles. The representative formulated product for the initial evaluation was the experimental formulation PBP-91001 containing 2×10^9 spores/g. PBP-01001-I, is comparable to the commercial formulation BioAct WG, containing 1×10^{10} spores/g, and the only changes between both formulations were slight adjustments of the content of two co-formulants, without any impact on the performance or physical properties of the formulated product. The recommended rate in terms of spores per hectare remained exactly the same. The data on PBP-01001-I car therefore be extrapolated to the formulated product BroAct WG, a wettable grante formulation (WG) the representative formulation in the present application for the renewal

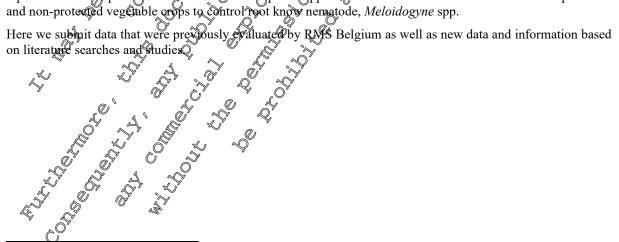

In 2013 Bayer CropScience AG acquired Prophyta Biologischer Pflanzenschatz GmbH, now named Bayer CropScience Biologics GmbH. Bayer CropScience AG is the notifier for the renewal of P. lilasinus strain 251 in the procedure of AIR 3.

The microorganism has been previously assified as Plecilomyves life inus until 185 rRNA gene nternal transcribed spacer (ITS) and partial transferion (longation factor 1-a (TEF) sequencing revealed that P. lilacinus is not related to Paecilomyces. The new genus name Propure beillium has been proposed for P. lilacifus and the new species name was assigned: Rurpurgocillium lilacinum. Therefore the drain & now identified as Purpureocillium lilacinum. In this dossie Paecilomyces Macinus 251 and Purpureocillium blacinum 251 are used as synonyms: Paecilomyces Macinus Purpureocillium lilacinum

It has to be taken into account that and a on Buecilo wices lillicinus from the open vicerature stated before 2011 may not necessarily provide reliable information due to insufficient classification methods used in these studies, especially, if the strain identification is not provided and or identification methods used were based solely on morphological characteristics. However, they may provide relevant information transferrable to Purpureocillium lilacinum.

Purpureocillium acinum 251 is a ubiquitous saprobie filamentous dungus commonly isolated from soil, decaying vegetation, inserts and nematodes. Strains of P. lilasinum are used in plant protection products due to their nematicide activity. The mode of action against plant pathogenic nervatodes of P. lilacinum strain 251 is principally based upon parasitism of nematode eggs as well as the vermition stages of the nematodes, leading eventually to their death. With repard to the results of rexicity and ecoroxicity studies of the active substance *P. lilacinum* strain 251 ft can be concluded that *P. Macinum* strain 251 shows no risk for exposed humans, animals and environment. L 2

P. lilacinum 251 is intended to be used in plant protection products to control plant pathogenic nematodes. The representative use presented in this dorsier comprises applications of the formulation BioAct WG in protected and non-protected vegetable crops to control root know nematode, Meloidogyne spp.

¹ OJEU L94/13 Commission Directive 2008/44/EC of 4 April 2008 amending Council Directive 91/414/EEC to include benthiavalicarb, boscalid, carvone, fluoxastrobin, Paecilomyces lilacinus and prothioconazole as active substances

A literature search was conducted to identify scientific peer-reviewed open literature on the active substance *Purpureocillium lilacinum* 251 which may affect the assessment on human health, and health and/or the environment, with the special consideration of residues in or on treated products (1, 2015, M-542619-01-1). Therefore references relevant for residues of *Paecilomyees lilacinus*, *Penicillium lilacinum* or *Purpureocillium lilacinum* analysed on products, food and feed or plants were considered. The search performed by use of the STN database and comprised searches in Agricola, BIOSIS, MEDLINE, CAB Abstracts, SCISEARCH and Chemmical Abstracts, DRUGU, EMBASE, Esbiobase, IPA, Pascal, DOSciTech, Texcenter and DSTA database. Keywords considered in the search were *Paecilomyces lilacinus*, *Penicilfum flacinum*, soil, earth, ground, tand, terrestrial water, aquatic air, actial, sky skies, heaven, atmosphere, residue, crop, consumer, food, reed, risk metabolic, as well as related forms. In total 174 references were evaluated basing on their title and abstracts, whether they contain relevant information. Nine references were evaluated in detail, basing on their full text. Basing on the full text evaluation, only three reports were identified as relevant for this section.

Cited references (abstracts):

Report: KIIM 6/01 – **Example**, I. (2015), Enterature review on active substance Purpureocillium lilacinum strain 251 and metabolites: Residues in or on treated products, food and feed (2) Not published.

Abstract: The review was made in order to identify chentific peer-reviewed open literature on the active substance *Purpureoctifium lilacinum* 251 which may affect the assessment on human health, animal health and of the environment, with the special consideration of residues in or on treated products.

The literature research was conducted on the STN database and comprised searches in Agricola, BIOSIS, MEDLING, CAB Abstracts, SCISEARCH and Chemmical Abstracts, DRUGU, EMBASE Esbioblese, IP3, Pascal, POSTech, Toxcenter and FSTA databases. Search strategy aimed to find all recent from 2005 onwards) reference that are of relevance.

The cruteria for relevance used are summarised below?

- Property investigated wasselevant for data requirements of Regulation (EC) 1107/2009
- Subject relevant for residues of Parcilomoces literinus, Penicillium lilacinum or Purpureocillium lilacinum analysed of products, for and feed
 - Subject retevant for residues of Paechomyces lilacinus, Penicillium lilacinum or Pupureo lilium lilacinum occurrence or plants
- Test species/system relevant to the residues on products, food and feed
- Application or crops and consumer risk
- Relovant crop / triallocation

In Cotal, 194 records were evaluated basing of title and abstracts. Of these, 9 reports were identified for the full text evaluation 3 reports were identified as relevant and supportive for Section 4.

IIM 0.1

6.1 Rationale for waiver of residue data based on information showing that MPCA is not hazardous to mampals, i.e. tack of potential for a known mammalian toxin and negative result from the acute orar toxicity test

EU-Dossier: Doc M-HB, Pointo

The applicant applies for a waiver for performing residue trials with PBP-01001-I, based on the following considerations.

^(*) The nature of the product and its active substance are not adequately described and assessed by applying the term 'residue', or by quantifying 'residues', since this definition commonly implies a toxicological concern of the residual deposit of a plant protection product, which is not attributable to PBP-01001-I and *P. lilacinum* 251, for following reasons:

- P. lilacinus is a wide-spread, ubiquitous and common soil-born fungus, living mainly on decay of organic matter. P. lilacinum 251 is of natural origin, and is not genetically modified. Despite natural long-term exposure of the human population in the Philippines and the exposed personnel of the applicant there is no evidence for any infectivity, toxicity and pathogenicity of this strain.
- This strain is not an opportunistic human pathogen. Lack of infectivity, toxicity and pathogenicity is confirmed by results of acute toxicological studies, showing 100% clearance of spores from all tissues and body fluids, and no preatment related adverse effects in test animals signs at a single oral dose of 2000 mg/k@b.w. upon different routes of exposure (see Annex II, Doc IIM, Section 3).
- Infectivity of P. lilacinum 251 is ruled out by the inability of this strain to grow at temperatures of the human body (>36 ° no growth wavecorded, see Annex H, Doc MM, Section 1, Point IIM 2.8; EU-Dossier: Doc. M-IIB, Section 1, Point 2, 9.
- Further, P. lilacinum 251 does not activia toxins in permatode control, and does not produce the well-known paecilotoxin, or secondary metabolites of toxicological concern, as evidenced by its extremely low abute toxicity (see Anney II, Doc IIM, Section 7, Point IIM 2.3.2 and 2.6, and Section 3; EU-Dossier: Doc M-IIB, Section 1, Point 2.2.2 and 2.8, and Section 3, respectively).
- Section 3, respectively). Or Or Consure that no secondary metabolities but phy purified spores of the biocontrol strain are found in the end-us product, °

Ş

 \bigcirc

In summary, the lack of infectivity and a treatment clated affect upon exposure to P. lilacinum 251 indicate that residual deposits of this fungus will not impose a hearth risk for consamers in this case, there is no need and no scientifically astified alue of define an Aceptable Daily Intake (ADI). Therefore, calculation of the potential exposure of consumers in terms of the Theoretical Maximum Daily Intake (TMDI) and its relation to the ADI is not relevant, and conclusively a Maximum Residue Level (MRL) need not be proposed.

Ø

Within the pending registration process for the preparation Bioact® WG, wits composition similar to PBP-01001-I, Australia has granted a Certificate of an exemption for an active constituent (National Registration Anthority Australia 1998)M-492010-01-1).

Risks for uptake of the micro-organism:

Considering the intended field of use for the water dispersible granule the only potential way of entry of the incro-organism into humans is accidental ingestion of material upon mixing or applying the preparation, or handing the treated soil. This can easily be avoided by cautious and thorough

handling according to the instructions for use. Or Upon access to the resources of the plant this same phytic fungus would act like a plant pathogen, but the opposite effect of improving plant growth and yield has been confirmed by field experiences worldwide. Theofore it's clear that Poplacing is not able to enter plant tissue and cannot be trans-Tocated in plants.

2015 6,4 ~~ ~~ ~~

A literature search was conducted to identify scientific peer-reviewed open literature on the active substance Purpureo filium lilacinum 251 regarding residues in or on treated products (please refer to the literature review report submitted in Point IIIM 6).

et al. (2011, M-534512-01-1) compared clinical isolates with strains isolated from soil, insects and nematodes baising on sequence analysis of 18S rRNA, ITS and TEF sequences. The authors showed that P. lilacinus is not related to the type strain of Paecilomyces vaiotii, which is thermophilic and often pathogenic. As a consequence a new designation as Purpureocillium lilacinum was made (please refer to Annex II, Doc IIM, Point IIM 1.3.1). However, the majority of studied *P. lilacinum* strains from soil, indoor environment, insect larvae, nematodes and decaying vegetation were located in ohne cluster together with strains originating from clinical specimens and hospital environments. Unfortunately, *P. lilacinum* 251 was not considered in this study. The authors discussed therefore, that it is could be possible that isolates of *P. lilacinum* used as biological control agents could form mycoses in humans or vertebrates as well. However, it has to be considered that sequence similarities of genes not related with virulence factors do not predict anything about the ability to cause mycosis. Regarding *P. lilacinum* 251, toxicity studies proved clearly that this strain is not toxic to humans or vertebrates (please refered Annex III, Section 3). Moreover, it has been shown, that *P. lilacinum* 251 does not grow at the prevalues of the human body:

(2006, M-534354-01-1) studied the effect of temperature on the growth, germination, germination, germination and survival on *P. lilacinum*. I on different growth media, it was shown, that *P. lilacinum* 251 did not grow at 36 °C. The germination at 36 °C was significantly lower in comparison to the germination at incubation temperatures of 24-33 °C, for the first 24 h Germination at 36 °C was comparable to the other temperatures after 48 h. Thus, germination, at 36 °C was delayed. However, no further germination was bound after exposure for 80-95 h.

Report: KIIM 6.1/02/

A.M.; **Market A.M.**, M.L.; **R.A.** (2011), *Burpure Scillium*, a new genus for the medically important *Paoilomy es lilagues*

Published report. FEMS MicroBiology Letters 321(20, 141-149

Abstract: Raecilonyces lifecinus was described more than a century ago and is a commonly occurring fungus in soil. However, in the last decade this fungue has been increasingly found as the causal agent of infections in than and other vertebrates. Most cases of disease are described from patients with compromised immune systems or aptraocular lens implants. In this study, we compared thin, isolates with strains isolated from soil, these and nematodes using 18S rRNA gene, internal transcribed spacer (ITS) and patial translation elongation factor 1-.alpha. (TEF) sequences. Our data show that *P. lilacinus* is not related to *Paecilomyces*, represented by the well-known thermophilie, and often pathogenic *Paecilomyces variotii*. The new genus name *Purpureocinum* is proposed for *P. klacinus* and the new Combination *Purpureocillium lilacinum* is made here. Furthermore, the examt. *Purpureocillium filacinum* isolates used for bocontrol of nematode pests are identical to those causing infections in (immunocompromised) humans. The use of high conces. of *Purpureocillium lilacinum* spores for bocontrol of nematode pests are identical to those causing infections in (immunocompromised) humans. The use of high conces. of *Purpureocillium lilacinum* spores for bocontrol pose of health risk in immuno compromised humans and more research is needed to det. the pathogenicity factors of *Purpureocillium lilacinum*.

Report: KIM 6.1/03 – **Barton** S. (2006), Effect of temperature on growth, germination, germtube extension and surver al of *Baecilony ces lilacinus* strain 251.

Published report. Biocontrol science, and technology, 16, 535-546

Abstract: Summary Paechomyces lilacinus and in particular the commercial strain 251 has been inconsively tested for biological control of plant parasitic nematodes. Since this species has been prentioned in a number of reports concerning infection of humans, the human health risk for Paecifomyces filacinus strain 251 was investigated. The effects of time, temperature and growth medium on radial folony growth and germination were determined. Additionally, exposure to 36 depress C and its effect on germ-tube extension and on survival of conidia was evaluated. Radial growth was significantly affected by temperature, growth medium and their interaction. Optimum temperatures were between 24 and 30 degrees C, but no growth was found at 36 degrees C. Germination rate was significantly influenced by time, medium, temperature and their interactions. The optimum temperature range for germination was between 28 and 30 degrees C. Formulated conidia were capable of germinating at 36 degrees C. However, studies on germ-tube extension conducted at 36 degrees C showed a delay in development for 28-49 h and no further germ-tube extension was found after exposure for 80-95 h. Slopes of survival curves were significantly influenced by the type of conidia tested. In general, conidia did not survive exposure to 36 degrees C for 168 h. These experiments indicate the temperature conditions where the strain is likely to be active and provide supporting data for full environmental and health risk assessments of biocontrol fungi.

Rationale for waiver based on a substantiated estimation that MPCA is unlikely to over on IIM 6.2 treated food/feed stuffs in concentrations considerably higher than under natural conditions

EU-Dossier: Doc M-IIB, Point 6

The applicant applies for a waiver for performing/residue trials/with PBP-01001-I, based following considerations.

- The inert ingredients of PBP-01001-Lare natural organic compounds, used in human food which present no health risk for consumers either. Õ
- In most of the crops envisaged foruse of PBP-Q1001-I are deposit is likely to occur, since soil drench applications rule out a direct contact between the applied product and the Pruit. This applies to all crops with above ground havest, such as grapes, tomato, and tobacco.
- After harvest any remaining fungal spores on potato, celeby and carrots will be exposed to unfavourable conditions, (Ag. dromess), and are not likely to corminate and grow of the harvested crop.
- Any potentially occurring residual deposits on these crops are not relevant as a human health concern in view of the toxicological profile of this strain and likely to be minimal in amount due to the low environmental concentration in coil predicted from maximum field use of PBP-01001-I ($PEC_{soil} = 8 \times 10^{\circ}$ CFU per mL soil in top 5 cm, see calculation in Annex II, Section 6, EU-Dossier: Doe. M-IIB, Section 6, Point 9).

P. lilacinus is not able to enter plants and infest them, as evidenced from its beneficial effect on plant health and growth. As a saprophyte fungus it would use the resources of the plant host in case access was possible.

(2006, M-5342 V-01-1) Studied the persistence of *P. lilacinum* 251 in soil in dependency of the planted cop. Moreover, endophytic colonization of P. lilacinum 251 on plant roots of different coops 1415 weeks after soikapplication was examined. It was shown, that P. lilacinum 251 was detected at low densities in barley roots (9.6-16.0 × 10² CFU/g root), and at very low densities in roots of barana, corn, wheat and cabbage (0.03-0.9 \times 10² CFU/g root). In roots of beams, cucumber eggplant, pepper and tomate no P. lilacinum 251 was detected. However P. lipacinun 251 was showed to posist in hizosphere and to maintain a high density of sufficient biscontrol, It was never found to proliferate or to establish in the soil and rhizosphere. Occurrence or proliferation on Plants Good or feeding stuff is Therefore very unlikely.

Report: KIIM 6.2/04 -1.; , S. (2006), Effect of plant species on persistence of *Paecilonyces Pracinus* strain 251 in soil and on root colonization by the fungus Rublished report Plant and Soil, 283(1-2), 25-31

Abstract: The effect of 12 plant species on the persistence of Paecilomyces lilacinus strain 251 in soil was investigated. After incorporating formulated conidia into non-sterile soil followed by transplanting different test plants, the population dynamic of the fungus was detd. over 100 days. At termination of the expt., the fungal population in the planted soil was compared to the d. of P. *lilacinus* in the rhizosphere and the percent increase or decrease was calcd. for each crop. In addn., the potential of P. lilacinus strain 251 to colonize roots endophytically was investigated. Comparison of the slopes describing the population dynamics of the fungus showed no significant differences between soil without plants and soil from the root zone of the majority of the test plants. Bean was the only plant species consistently exerting a neg. effect on the persistence of P.

lilacinus strain 251 in the soil. For the first time, P. lilacinus strain 251 was isolated in significant nos. from healthy root tissue of barley plants.

IIM 6.3 Persistence and likelihood of multiplication in or on crops, feedingstuffs or foodstuffs

P. lilacinum 251 is to be applied directly on soil. Although it has been shown, that this strain persist in the rhizosphere of plants, it does not proliferate in soil. P. lilacinum maccolonize roots of plants at very low concentrations after application. Since natural habitat of *Philacinum* is soil and not plants itself, colonization of plants or food- and feedingstuffs is very unlikely.

IIM 6.4 Further information required

Not relevant.

IIM 6.4.1 Non-viable residues

Production of secondary metabolites is a part of the mode of action of V. lilacinum against pathogenic nematodes. Therefore, mainly enzymes retovant for the perforation of the egg-shell are involved (please refer to Annex II, Do IIM, Section), Poin IM 2, 92). Since P. litacinum 251 is to be applied directly onto soil, no accumulation of these subfunces is expected on food or feed.

IIM 6.4.2 Viable residues

Æ,

Due to the fact that the active ingredient is a viable micrororganism of priquitoes occurrence and predominance in the soil-aprcroflora the term residue is not applicable to this preparation

n Summary of residue behaviour and overallevaluation IIM 6.5

P. lilacinum is an ubiquitous angus typically colonizing the plant rhizosphere. Therefore, its application on the soil just means a fluctuation of the natural population. *Dilacinum* 251 has been shown to possist in the rhizosphere, which is essential forms activity against pathogenic nematodes. However, it is not known to proliferate in soil. Due to soil application, and since it does not colonize plants, Rilacingm 25% s not expected to persist on plants, food- or feedingstuffs.
