CP 10 ECOTOXICOLOGICAL STUDIES ON THE PLANT PROTECTION **PRODUCT**

INTRODUCTION

The purpose of this MCP-Dossier Section 10 is to support the approval process of the ne substance isoflucypram in the territory of Europe under (EC) No. 1107/2009.

Isoflucypram EC 50 as the representative formulation is an emulsifiable concentrate (EC) contains 50 g/L isoflucypram for use in cereal crops.

Isoflucypram is a novel broad spectrum fungicide of the chemical class of Nevclop opyl-N-benz pyrazole-carboxamides with an outstanding efficacy against the major economically important tongal diseases of cereal crops (wheat, triticale, rye, barley and oats) and excellent crop serety. Since isoflucypram is an SDH inhibitor and thus assigned to the FRAC registance Group 7 the application scope of isoflucypram-containing products on cereals with only one Poliar spray at a maximum of 75 g a.s./ha supports an effective anti-resistance orangement strategy

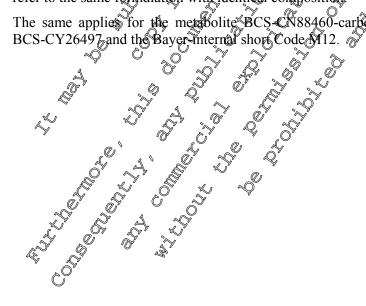

Tailor-made and broad spectrum isoffacypram combinations show highly beneficial properties in terms of plant physiology beside the long-lasting and certain curative efficacy to control fungal diseases and to maximize the full fold potential of the cereal crops.

This document summarises at ecotoxicological data, risk assessments and classification proposal, which are relevant for the approval of isoflucystram and the proposed intended uses, including the representative uses, under Regulation (EC) No. 1107/2009 in accordance with the requirements laid down in the Commission Regulation (EU) No 283/2013 and under Classification Regulation (EC) No 1272/2008.

Details of the literature search undertaken for isoflue prant its metabolites and products have been summarized in the Document MCA Section %

Throughout the development of the formulation Isofacypram EC 0 the following synonyms may have been used and referred to in individual study reports: Sayer Code: BCS-CN88460 EC 50 and the Bayer-internal abbreviation short Code: ISY EC 50. Alk products described by either of these codes refer to the same formulation with dentical composition.

The same applies for the metabolite BCS-CN88460-carboxylic acid for which the Bayer Code is

Use pattern considered in this risk assessment

	Long term	Mallard duck	NOEC 1000 ppm NOEL 60 mg a.s./kg bw/d	; ; ; ; ; ; ; ; ; ; ; ; ; ; ; ; ; ; ;

Endpoints bold considered relevant for risk assessment

Metabolites of isoflucypram

The metabolite BCS-CN88460-propanol-Glyc-MA (M21) is a plant metabolite, which was found in wheat hay at an amount of 10.3% TRR in a metabolism study with wheat plants (see MCA Summary Section 6, Point 6.2). Therefore it may be ingested by herbivorous birds or mammals. This metabolite is assumed to be cleaved under acidic conditions in the stomach of birds and mammals to the metabolite BCS-CN88460-propanol (M01). The metabolite M01 was found in the metabolic pathway in rat and hen (see MCA Summary Section 5, Point 5.1.1 and MCA Summary Section 6, Point 5.2). Therefore the metabolite M21 is covered by the risk assessment with the active substance isoflucypram.

Table 10.1.1-2: Relevant generic avian focal species for Tier 1 risk assessment

Crop	Scenario	Generic focal species	Representative Species	Shorteut Long-term RA based on RUDm	value (SV) Acute RA based on R4(D)
Camaala	BBCH 30-39	Small omnivorous bird "lark"	Woodlark (Ludula arborea) F	\$5.4 \$	12.0
Cereals	BBCH ≥ 40	Small omnivorous hird "lark"	Woodlask Lullula,arborka)	A 35° &	7.2

ACUTE DIETARY RISK ASSE

Tier 1 acute Osk assessment or birds Table 10.1.1-3:

Crop scenario	Generic focal speces	Oppl. rate kg a Tha		DDD	LD ₅₀ © [mg/a.s./kg/ boy]	TERA	Trigger
BBCH 30-39	Small synnivors as bird "lark "	0.075	12.0	0.98	~	> 2222	10
BBCH ≥ 40	Small omnivorous Bird &	0.079	7 2 \$ 50	% 54	> 2000	> 3704	10

The TERA values values valued in the acute risk assessment on Tier 1 level exceed the a-prioriacceptability trigger of 10 for attevaluated scenarios. Thus the acute risk to birds can be considered as low and acceptable without need for further, more realistic risk assessment.

Acute risk assessment for birds drinking contaminated water from pools in leaf whorls

For the fungicidal use in cases smen in this evaluation (cereals) the leaf scenario is not considered relevant according to the ASSA Suidance Document for risk assessment for bird and mammals (2009).

Acute risk assessment for birds firinking contaminated water from puddles

Table 10.1.1-4; Evaluation of potential concern for exposure of birds from drinking water (escape clause)

Crop (Approximate × MA)	~O	AR _{eff} / LD ₅₀	"Escape clause" No concern if ratio	Conclusion
Cencals 1579.6 75	> 2000	< 0.04	≤ 3000	No concern

According to the EFSA Guidance document for risk assessment for bird and mammals (2009) "no specific calculations of exposure and TER are necessary when the ratio of effective application rate

LONG-TERM REPRODUCTIVE ASSESSMENT

Table 10.1.1-5: Tier 1 reproductive risk assessment for birds

(in g/ha) to relevant endpoint (in mg/kg bw) does not exceed 3000 in the case of more sorptive substances ($Koc > 500 L/kg$)." This is the case for isoflucypram and therefore the acute risk for birds								
from drinking water that may contain residues from isoflucypram is acceptable.								
LONG-TERM REPRODUCTIVE ASSESSMENT								
Table 10.1.1- 5	: Tier 1 reproducti	ve risk asses:		us ————————————————————————————————————	A O			
Crop	Generic focal species	Appl. rate [kg a.s./ha]	SV _m MAF _r	n f _{TWA}	NOAEL mg a.s./ TER ₁₈ kg bw/d]	Trigger		
BBCH 30-39	Small omnivorous bird "lark"	0.075	5.4	0.21	286			
BBCH ≥ 40	Small omnivorous bird "lark"	0.073	3.3	0.13	9 467			

The TER_{LT} values calculated in the chronic visk assessment on Tier 1 level exceed the a-prioriacceptability trigger of 5 for all evaluated scenarios. Thus, the Yong-term risk to birds can be considered as low and acceptable without need for further, more realistic risk as essment.

Long-term risk assessment for biods drinking contaminated water from puddles

Table 10.1.1-6: Evaluation of potential concern for exposure of birds from drinking water (escape clause)

Crop	Koc	AReft	NO(A)EL	Ratio 🦠	"Escape	
	[L/kg]	Application rate MAF)	mg a.s./	(Application rate)	Chause?	
	3	≫rate <u>,</u> ∗ MAF) ຶ	kg bw/d]	MAF) (NO(A)EL)	No concern	Conclusion
	*	[gQx.s./ha©				
Cereals	15, 9.6	\$.7 . 9	\$ 60	1 [©] 25	⊘≤ 3000	No concern

According to the EFSA Guidance Document for risk assessment for bird and mammals (2009) "no specific calculations of exposure and TER are recessary when the ratio of effective application rate (in g/ha) to relevant endpoint (in mg/kg/bw/d) does not exceed \$600 in the case of more sorptive substances (Koc > 500 L/kg). This is the case for isofline ypran and therefore, the long-term risk for birds from drinking water that may contain residues from isofficypram is acceptable.

RISK ASSESSMEND OF SECONDARY POISON

Table 10.1.1-7: Log Pow values

<u> </u>		
Substance	log Pow	Reference
Isofbacypram		KCA 2.7/01 ; 2014; M-484656-01-1
BCS-CN88460 (M12)	2.14 (pH 5) -carboxylic acid 2.14 (pH 5) 0.22 (pH 7) 1.1 (pH 9)	KCA 2.7/02 ; 2015; M-519996- 01-1

Effects on secondary poisoning have been assessed for isoflucypram, due to a log Pow value above 3. The metabolite BCS-CN88460-carboxylic acid (M12) is assessed in the aquatic risk assessment and in the risk assessment for soil organisms. The Log Pow values of this metabolite are below 3 at ecologically relevant pH values. Therefore there is no risk to birds from BCS-CN88460-carboxylic acid (M12) through secondary poisoning.

The TERovalues for isoflucy fram are above the frigger of concern of 5, indicating no risk from secondary poisoning for earthworm, and fish-earing birds.

Acute oral toxicity

For animal relater reasons, no acute of toxicity study with the preparation was performed. Such a study is not deemed necessary, given the fact that the active substance is not acutely toxic to birds.

Higher tier data on birds

In view of the results presented above, no further studies were necessary.

CP 10.1.2 Effects on terrestrial vertebrates other than birds

Endpoints in **bold** considered relevant for risk assessment

Metabolites of isoflucypram

The metabolite BCS-CN88460-propanol-Glyc-MA (\$121) is a plant metabolite which was found in wheat hay at an amount of 10.3% TRR in a metabolism study with wheat plants (see MCA summary Section 6, Point 6.2). Therefore it may be ingested by herbivorous birds or mammals. This metabolite is assumed to be cleaved under acidic conditions in the stomach of birds and mammals to the metabolite BCS-CN88460-propanol (\$101). The metabolite M01 was found in the metabolic pathway in rat and hen (see MCA Summary Section 5, Point 5.1) and MCA Summary Section 6, Point 6.2). Therefore the metabolite M21 as covered by the risk assessment with the active substance isoflucypram.

Table 10.1.2-2: Relevant generic focal species for Tier 1 risk assessment

Crop	Scenario	Generic Local species	Represontative species	Shortent va	lue (SV)
	BBCH 20		l, «() »	Shortent va Kong-term RA baset on RODmean	Acute RA based on RUD ₉₀

IRR(IH > III)	Small omnivorous mammal "mouse"		2.3			0.091		1021	

The TER_{LT} values calculated in the reproductive risk assessment on Tier 1 level for wild mammals exceed the a-priori-acceptability trigger of 5 for all evaluated scenarios. Thus, the long-term risk to wild mammals can be considered as low and acceptable without need for further, more realistic sight assessment.

S				ng contaminated water	Ť	er (escape clause) &
Crop	K _{oc} [L/kg]	AR _{eff} (Application rate × MAF) [g a.s./ha]	NO(A)EL [mg a.s./ kg bw/d]	(Application rate	"Escape clause" No concerto if ratio	Consusion
Cereals	1579.6	75	92.9	0.81	⁰ ≤ 3 000 (No concern

According to the EFSA Guidance Document for risk assessment for bird and mammals (2009) "no specific calculations of exposure and TER are necessary when the ratio of effective application the (in g/ha) to relevant endpoint (in mg/kg/bw/d) does not expeed 3000 in the case of more sorbive substances (Koc > 500 L/kg)." This is the case for jet flucy fram and therefore, the long-term fish for mammals from drinking water that may contain residues from is of ucyptam is acceptable

RISK ASSESSMENT OF SECONDARY POISONING

Effects on secondary poisoning have been assessed for isoflucy pram, due to log Pow value above 3. The metabolite BCS-CN8&460-carboxylie acid (M12) is assessed in the aquatic risk assessment and in the risk assessment for soil organisms. The Logo Pow values of this metabolite are below 3 at ecologically relevant of values. Therefore there is no risk to firds from Bos-CN88460-carboxylic acid (M12) through & condary post ning

Aculation presented in Table 10.1.1-9.

Long-term toxicity exposure ratio for fish-eating mammals

Table 10.1.2-9: Tier 1 long-term ETE and TER calculation for fish eating mammals

Substance	Isoflucypram
PEC _{fish} [mg/kg]	1.0064*
FIR/bw	0.142
DDD [mg/kg bw/d]	0.14
NO(A)EL [mg/kg bw/d]	92.9
TER _{LT}	663
Trigger	5

^{*}See calculation presented in Table 10.1.1-10.

The TER values for isoflucypram are above the trigger of concern of 5 indicating no risk from secondary poisoning for earthworm- and fish-cating manmals.

CP 10.1.2.1 Acute oral toxicity to mammals

According to the Regulation (EC) No. 272/2008 Affacts 3 1.3.6.1 The classification of a mixture such as a formulated plant protection product may be estimated with a calculation roothod.

The representative formulation IsoTucypram EC 50 contains no ingredients relevant for calculation of an oral ATEmix. Therefore, ISY EC 30 should not be classified for oral oxicity. For details, please refer to the CONFIDENTIAL Document JCP, Point 7.4 and Point 12.3

Conclusion

As the formulation is not classified for acute oral to city the formulation is not considered to be more toxic than the active substance.

CP 10.1.2.2 Higher tier data on mammats

In view of the result@presented above, no further studies were necessary

CP 10.1.3 Offects on other terrestrial vertebrate wildlife (reptiles and amphibians)

Information on effects isothecypram on reptiles or amphibians is not available. No guidelines for studies with terrestrial amphibian life stages and reptiles are available and no risk assessments schemes are established to far. Therefore no further studies can be suggested for these groups of organisms.

CP 10.2 Effects on aquatic organisms

The risk assessment is based on the current guidance: EFSA PPR Panel (EFSA Panel on Plant Protection Products and their Residues), 2013. Guidance on tiered risk assessment for plant protection products for equatic organisms in edge-of-field surface waters. EFSA Journal 2013;11(7):3290.

Bold: endpoints used in risk assessment

Nom = nominal concentrations, mm = mean measured concentration, gmm = geometric mean measured concentration

Selection of endpoints for Tier 2 product risk assessments

The effect data for the product Isoflucy fram EC 50 observed for aquatic organisms are very similar to the effect data derived for the active substance.

In the table below the observed endpoints for the active substance and the product are compared to each other. The difference observed for fish with respect to active substance and the product is 1.2 overall and 1.4 based on data from the studies with the rainflow trout only. The difference between the active substance and the product based endpoint for Daphitia magna is 4.7 only.

Therefore it can be dated that the formulation is not increasing the toxicity of the active substance.

Table 10.2- 2: Endpoints for fish acute and daphnia acute Factors between a.s. and product)

	~ V	\circ	\sim

~Q⁻ (
Isoflucypram a.s.	Daphnia magna 😽 🎺	₂ 9.201	1.7
Isoflucy ram EC 50	Daphnia magna &	0.117	
Geometric mean: 🔏	Daphinia magna 🗷 🧷	0.153	

As for the active substance wore species have been investigated compared to the product we propose to consider this information as well for the product based risk assessment. Otherwise the environmental risk assessment would not make full use out of the existing information. Therefore we propose to use the Tier 2A acwell for the product risk assessment. To consider the fact that rainbow trout and Darbinia nagna data exist twice, the notifier proposes to use the geomean for data resulting from active substance testing and from product testing, before using the data in a Tier 2A approach.

A Endpoints in the study report were reported based on the formulation only. For this table the endpoint is converted to mg a.s./L based on the reported content of isoflucypram of 5.2%.

B Endpoint based on geometric mean of the given relevant endpoints of acute or chronic studies with the active substance and the formulation. Detailed information given below under Selection of sudpoints for Tiers product risk assessments'

^C Endpoint corrected for purity. In study report uncorrected values are sted.

D Endpoint based on geometric mean of the given reteant endpoints of acute or chronic studies with the active substance and the formulation. Detailed information given under MCA\$2: 'Selection of indpoints for Tier 2 risk assessments with the active substance'

Fish acute

If more species are tested as required according to the data requirements laid down in Regulation (EU) No 283/2013 it might be appropriate to use Tier 2A. In case of isoflucypram the data requirements were exceeded for acute testing of fish. Data for the different fish species: The trout (Oncorhymenus mykiss), the fathead minnow (Pimephales promelas) and the sheepshead minnow (Cyprifodon) variegatus).

The available data are not sufficient to use the Tier 2B, the Species Sensitivity Distribution the use of the Tier 2A, the geomean assessment factor approach.

As two data points are available for Oncorhynchus mykiss (product and active geomean out of the respective two endpoints is used.

The following LC_{50} values (based on the real content of the active species are then available:

Table 10.2-3: Endpoints for fish acute

Species	Species (Scientific name)	96h LCso (mga.s./La)
Rainbow trout	Oncorhynch mykis	0.082 (Geometric noan of a.s. and product study)
Fathead minnow	Pimephales prometas	
Sheepshead minnow	Cypringson variegtaus	0 4 Q 0.544 0 V
Geometric mean:		√ √ 0.153 ©

For the taxonomic group of fish the data requirements (one species) were exceeded. Data for three species are available. Therefore the geomean 96 by CC50 for these three species was calculated. Before this value can be used it has to be checked whether the geometric mean approach has been biased by introducing insensitive species. According to the Guidance on tiered risk assessment for edge of field sufface waters (EFSA 2013) an assessment of this ras to be made when the difference in sensitivity exceeds for 2 orders of magnitude. In case of fish a factor of 100 should not be exceeded. The highest and the lowest 96 if LC derived for fish and isoffocypram differ by a factor of 6.7. Therefore the use of the geometrian approach for the fish acute risk assessment is appropriate. In addition the chronic fish data can be used to check the appropriateness of the Tier 2A related regulatory acceptable concentration (RAC) for cute 15th of 0.00153 mg a.s./L. This RAC is a factor of 10.2 below the lowest observed chronic NOEC for fish, resulting from a Fish Early Life Stage (FELS) test with fathead mingow. The acute RAC based of Tier A for fish is even a factor of 12.9 below the Tier 2A chronic fish value based on the two existing FELS studies for fathead minnow and sheepshead

The above presented information demonstrates that the Tier 2A fish acute 96 h LC₅₀ of 0.153 mg a.s./L (product) and the resulting hier 24 RAC of 0.00153 mg/L is protective and can therefore be used within the aquatic risk assessment of the product Isoflucypram EC50.

Crustacean acute

minnow.

If more species are tested as required according to the data requirements laid down in Regulation (EU) No 283/2013 than It might be appropriate to use Tier 2a. In case of isoflucypram the data requirements were exceeded for acute testing of invertebrates, especially crustaceans. Data for two different crustacean sposies, the waterflea (Daphnia magna) and the mysid shrimp (Americamysis bahia) are provided. The available data are not sufficient to use Tier 2B, the Species Sensitivity Distribution but allow the use of Tier 2A, the geomean assessment. As two data points are available for Daphnia magna (product and active substance), the respective geomean out of the two endpoints is used.

The following EC₅₀ values (based on the real content of the active ingredient) for the two tested species are then available:

Table 10.2- 4: Endpoints for crustacean acute

Species	Species (Scientific name)	EC ₅₀ [mg a.s. /L]
Water flea	Daphnia magna	0.153 (48h, geometric mean of a.s. and product study).
Mysid shrimp	Americamysis bahia	0.270 (96h) ************************************
Geometric mean:	-	0.203

The resulting Tier 2A EC₅₀, based on information for the waterflew Daphnia magna and the physical shrimp Americamysis bahia is 0.203 mg/L.

The notifier proposes to use this value for the product risk assessment according to Toer 2A (geometria approach).

Selection of algae and macrophytes endpoints for risk assessment

Processes in ecosystems are dominantly rate driven and therefore the unit development per time (growth rate) is more suitable to measure effects in algae and matrophytes. Also, growth rates and their inhibition can easily be compared between species, test durations and test conditions, which is not the case for yield or biomass based endpoints. Following current state of science, the test guidelines OECD TG 201 and 221, the EleMethod C35 the Regulation for Classification and Labelling (Regulation (EC) No. 1272/2008), the PDR Opinion (EC) SA Journal 161, 1.44; 2007), the EFSA supporting publication 2015 (EN-92 published 22 December 2015) and also the EFSA Aquatic Guidance Document (AGD, 2013 noted by SCOCAH on July 10-10th, 2014), list growth rate as the relevant endpoint of the argae and the *Lemnas* growth inhibition test. Therefore the risk assessment is based on the ErC50, when available.

Metabolites

In the risk assessment the isoflucy fram metabolity BCS-CN88060-carboxylic acid (M12) has to be addressed:

The EFSA AGD (2013) stepwise approach was used for all metabolites to be addressed in the risk assessment.

- «X complete acute experimental data set is available for the metabolite BCS-CN88460-carboxylic acid (MV2)
- Based on the acute data 10 times less toxic on a molar basis than the parent) it can be concluded that BCS-CN88469-carboxylic acid (MF2) has lost its toxophore.
- Due to its limited formation in aquatic systems, no reliable degradation half-lives for BCS-CN88460-carboxync acid can be derived. As conservative approach it is assumed that the trigger for chronic risk assessment (Di 90 > 1d) is met for BCS-CN88460-carboxylic acid (M12)

According to the AGD stepwise approach, the parent chronic endpoints can be used in the metabolite risk assessment as surrogate values for all Ther 1 taxonomic groups. Thus the chronic risk assessment for the metabolite BCS-CNS 460-earboxylic acid (M12) is based on parent endpoints.

For use of isoflacypram in winter cereals acceptable acute risk to fish could be proven for most FOCUS Step 3 scenarios. For use of isoflucypram in spring cereals the risk assessment on the basis of FOCUS Step 3 PECs values is passed almost for all scenarios whereas for invertebrates acceptable risk could be proven for all FOCUS Step 3 scenarios.

A refined risk assessment for the use in winter and spring cereals for the acute risk to fish is presented below. Those scenarios are presented which do not pass the risk assessment at Tier 1.

Refined risk assessment (Tier 2a)

Winter cereals

Table 10.2- 10: Acute risk assessment based on FOCUS Step 3 for winter cereals

Compound	Species	Endpoint [µg/L]	RAC [#] [μg/L]	FOCUS Scenario	PE sw,max	RA©#≥ Ô PECsw

CHRONIC RISK ASSESSMENT FOR AQUATIC ORGANISMS

Table 10.2- 12: Chronic risk assessment based on FOCUS Step 2

Compound	Compound Species		RAC [µg/L]	PECsw.max %[μg/L]	RACE PLOSW
Isoflucypram EC 50	Algae, chronic Pseudokirchneriella subcapitata	E _r C ₅₀ 179	17.9 🖔		Yes
	Fish, chronic Oncorhynchus mykiss	NOEC 15.6	1.56		No o
Isoflucypram	Invertebrate, chronic Daphnia magna	NOEC 66 D	6.61	Q 9296	Yes
	Sediment dweller, chronic Chironomus riparius	NOEC \$5000	8500 °	l**/ al.	Yes O
	Algae, chronic Navicula pelliculosa	ErC ₅₀ > 2000	>\$00		Yes
	Aquatic macrophyte Lemna gibba	EC50 3020	> 300		Yes
	Fish, chronic # Oncorhynchus mykiss	NOEC 5.6	¥.56		Yes
BCS-CN88460- carboxylic acid (M12)	Invertebrate, hronic, # Daphnia magna O	NOEC 5 66.1	669	\$3090 °	Yes
	Algae Oronic Pseudokirchaeriella Sabcapijata	E _r C ₅₀ > 35100 %	35,100		Yes

^{*}As the metabolite is at least actively 10 times less toxic than the parent on a mother basis the chronic parent endpoints for all Tier 1 taxonomic groups can be taken as surrogates.

For isoflucypram the chronic trigger was not met for fish For the isoflucypram metabolite BCS-CN88460-carbox fic acid (MIQ) acceptable chronic risk could be proven for fish, invertebrates and algae. The consideration of the more realistic FOCUS Step 3 water concentrations is presented below.

Winter cereals

For the use of isoflucypram in coreals, calculated PEC/RAC ratios for the active substance isoflucypram indicate acceptable chronic risk for all aquatic organisms.

CP 10.2.1 Acute toxicity to fish, aquatic invertebrates, or effects on aquatic algae and macrophytes

For the reason of planned gobal registration more than the European data requirements had to be fulfilled. Especially for the United States additional studies are needed for a submission. These studies need to cover (among others) as well additional studies with fish as these data exist they have to be part of the submitted dossier and therefore have been submitted by the notifier for regulatory review.

Validity criteria	Required	Obtained
Mortality within the 48-hrsettling-in period	<u>≤</u> 5%	0%
Mortality in control during test	<u>≤</u> 10%	0%
Dissolved oxygen saturation	≥ 60%	≥ 94%

Analytical results:

The chemical analysis of BCS-CN88460 resulted in recoveries of 122 to 128% of nominal at east initiation in the freshly prepared test media. In the aged test media recoveries ranged from 85 to \$14%, Therefore, the analytical recoveries over the whole testing period of 96 hours ranged between 30% and 128% of nominal.

Since the analytical results confirm a correct dosing of the test item at test initiation and the toxicity has to be attributed to the tested formulation as a whole, all results were related to nominal test concentrations of the formulated product.

Biological results:

Observations

Lethal effects were observed in the two highest concentration of 1.42 and 2.84 mg form./L. All fish were dead within 24 hours at the highest test concentrations of 2.84 mg form/L. At 1.42 mg form/L one fish died within 24 hours of exposure and five further dead fish were observed at 1.42 mg form./L within 48 hours of exposure. After 72 hours at 1.42 mg form a nine fish were dead. No further mortalities were observed during the test. W

At 1.42 mg form./L. severe sub-lethal effects were observed all fish after 4 hours of exposure. At test termination (96 hours) the remaining first at the 1.42 mg form./L test level showed sub-lethal effects such as fish mainly on the bottom, fish lying on side or back on the bottom and showed reduced activity.

Cumulative mortality over the test period

Exposure time (hours)	24	48	96

Conclusion

The study meets the validity criteria and the endpoints based on nominal concentrations are:

LC ₅₀ 96 hours (95% C.I.):	1.29 mg form./L (1.19 – 1.41 mg form./L)
LOEC: lowest concentration with an effect	0.710 mg form./L
NOEC: highest concentration without adverse effects	0.355 mg form./L
LC ₀ : highest concentration without mortality	0.710 mg form./L
LC ₁₀₀ : lowest concentration with 100% mortality	2.84 mg form./L ^Q

Analytical results:

The accompanying chemical analysis of BCS N88460 in the freshly prepared test solutions at test initiation revealed measured contents between 105% and 114% of the aspired nominal concentrations. The corresponding concentrations of the aged test solutions at the end of the 48 hours exposure period ranged between 108% and 12% of nominal. No contaminations of BCS-CN88460 were detected in samples from unfreated water control As these measured concentrations ranged well within the recommended range of 80 – 120% of nominal, all reported results are based on nominal concentrations of BCS CN88360 EC 50 G by the test solutions.

Additional long-term and chronic toxicity studies on fish, aquatic invertebrates and sediment dwelling organisms

No additional studies were necessary based on the current data requirements. Please refer to Document

CP 10.2.3 Further testing on aquatic organisms

No studies were necessary based on the current data requirements. Please refer to Document MCA, Section Point 8.2.

CP 10.3 Effects on arthropods

CP 10.3.1 Effects on bees

The risk assessment has been performed according to the existing guidance in force at the time of the preparation and submission of this dossier namely the EU Guidance Document on Terrestroll Ecotoxicology (SANCO/10329/2002 rev 2) and EPPO Standard PP 300 Environmental Visk Assessment Scheme for Plant Protection Products – Chapter 10: Honeybeek

Regulations (EU) 283/2013 and 284/2013 require, where bees are likely to be exposed, testing of both acute (oral and contact) and chronic toxicity, including sub-lethal effects. Consequently in addition to the standard toxicity studies performed with adult bees (OECD 213 and 214) studies that describe the intrinsic chronic toxicity to adult honeybees and honeybee larvae were performed, which are provided under MCA Section 8, Point 8.3.1.

Further data on honeybees was generated under semi-field conditions with the representative formulation Isoflucypram EC 50, which is described in detail in this MCF Section 10:

- Semi-field brood studies following OECD Guidance Document No. 95 using a more registic spray scenario onto flowering *Photelia* covering effects on brood (eggs) and their development and colony parameters.
- Semi-field brood studies following EPPO 170 (4) using a more realistic spray scenario onto flowering *Phacelia* covering effects on portality, foraging activity as well as general colony development.

These tunnel tests with the pepresentative formulation Isoflucypram IC 50 according to OECD GD 75 and EPPO 170 are presented in the MCP-Summary, Section 10 under Point 10.3 5.5.

Risk assessment for bees &

The risk assessment for bees for isoflucypram is based on the application rates of 1.5 L prod/ha corresponding to 75 s.s./ha for applications in cereals using the endpoints (LD₅₀ values) for the formulation to flucypram E 50 and the active substance isoflucypram.

Hazard Qwötients

The risk assessment is based on Hazard Quotien Capproach (Q_H) by calculating the ratio between the application rate (expressed in g &s./ha) and the laboratory contact and oral LD₅₀ (expressed in μg a.s./bee).

 Q_H values are calculated using data from the studies performed with the active substance and with the formulation Q_H values higher than 50 undicate the need of higher tiered activities to clarify the actual risk to hopeybees.

 $Q_{HO} = \frac{\text{maximum applicatio n rate}}{-}$ [g a.s./ha or g total substance/ha] Hazard Quotient, oral: [µg a.s./bee or µg total substance/bee] LD₅₀ oral

[g a.s./ha or g total substance/ha] maximum applicatio n rate Hazard Quotient, contact: μg a.s./bee or μg to substance/bee LD₅₀ contact

Table 10.3.1-2: Hazard quotients for bees - oral exposure

Compound	Oral LD ₅₀ [μg a.s./bee]	Max. application rate [g/ha]	Hazard quotient ∙Оно	Trigger	A-priori & acceptable rist of adult begs
Isoflucypram tech.	> 109.5	75	< 0.69	Q\$0	yest
Isoflucypram EC 50	69.1	75	1.09	50 0	yes v

The hazard quotients for oral exposure are below the validated trigger value for ligher tier testing (i.e. $Q_{HO} < 50$).

Table 10.3.1-3: Hazard quotients for bees—contact exposure

Compound	[μg a.s./bee]		Hazard Trigger quotient	Aspriori A acceptable risk For adult bees
Isoflucypram tech.	> 100.0	75, " "	< 0.75 20	yes
Isoflucypram EC 50	14.1 🗳 🐒	75	5.32 \$ 50	yès

validated trigger value for higher tier testing The hazard quotients for contact exposure are below the (i.e. $Q_{HC} < 50$).

Further considerations for the risk assessment

The active substance soflucypram (tech or non-toxic to have with acute LD50 values for adult honeybees in excess of $100 \,\mu g$ a.s./bee for oral and contact routes of administration. The formulated product Isoffucypram EC 50 is slightly toxic to honeybees with an acute oral LD₅₀ value of 69.1 μg a.s./bee_and 14.1 µg als./bee_for contact toxicity. All calculated HQ values based on these toxicity endpoints are considerably lower than the levels regarded to indicate a risk to bees.

Acute laboratory toxicity tests on adult bumble bees resulted in LD50 values which are in excess of 200 and 100 µg a.s./comble bee for oral and contact exposure respectively, indicating that bumble bees are not more sensitive fran honeybees to isoflucymam.

Isoflucyprain was further subjected to inronic laboratory testing with adult honeybees (KCA 8.3.1.2; (Å.; 2015; №540163-01-19.

This chronic study was designed as a dose response test by exposing adult honeybees for 10 consecutive days to pominal concentrations of 208, 417, 833, 1667, 3333 mg isoflucypram/kg feeding solution. The actual test was conducted by using the formulated product Isoflucypram SC 200 (202.3 g/L) to overcome the comitations of solubility that a technical active ingredient may have. After exposing hopeybees for ten consecutive days exclusively to feeding solution containing the a.s. at the respective treatment leves, the 40 day LC₅₀ (Lethal Concentration) was determined to be > 3333 mg isoflucypram/kg/which corresponds to a LDD₅₀ (Lethal Dietary Dose) of >89.7 μg a.s./bee/day. The respective NOSC (No Observed Effect Concentration) for mortality was determined to be >3333 mg isoflogypragy/kg, which corresponds to the NOEDD (No Observed Effect Dietary Dose) of ≥ 89.7 µg a.s. bee/day. The findings from this study indicate that isoflucypram is of equally low toxicity over a 10-day period compared to acute exposure.

Additional laboratory testing was performed with Isoflucypram by feeding of honeybee larvae (KCA 8.3.1.3; 2017; M-587515-01-1).

This repeated feeding study was designed as a dose-response test by exposing young honeybee larger at three feeding events to nominal concentrations of 10.4, 26.0, 65.0, 162 and 406 mg a.s./kg diet, equivalent to cumulative doses of 1.60, 4.00, 10.0, 24.9 and 62.5 μ g a.s./larva per developmental period. After exposure mortality was assessed during the larval and pupal phase with a final assessment of adult emergence on day 22. As study endpoint the 22-day NOEC (No Observed Effect Concentration) for emergence was determined to be >406 mg isoflucypraty/kg, which corresponds to the NOED (No Observed Effect Dose) of \geq 62.5 μ g a.s./larva.

In order to clarify whether isoflucypram would pose a risk to honey be brood in particular and to the survival of adult honeybees and colony development in general under more realistic worst-case conditions, two higher tier semi-field honeybee brood studies were conducted according to the provisions of the OECD Guidance Document 75. Under these forced confined exposure conditions the representative formulation Isoflucypram EC 50 was applied at 75 g a 5 ha in tunner to the full flowering and highly bee attractive surrogate crop Phaselia amacerfolia. In the two semi-field 2016; M-549363-0 1 and (tunnel) tests conducted by M-581949-01-1 the honeybee colonies were exposed to spray residues by adjut bees foraging on flowers (nectar and pollen) from the treated plants. The bee colonies were kept within the turnels for approx. 1 week (confined exposure phase) and were then relocated out of the runners and transferred to a monitoring site without flowering crops and intensive agricultural activity for further monitoring for approx. 2.5 weeks. Daily, throughout the confined exposure phase, morality of worker bees, larvae and pupae was assessed along with assessments of foraging activity and behaviour. Mortality assessments were continued along with behaviour pround the have during the post-exposure observation period. Colony assessments (colony strength, broad area, food stores) were made before and after the confinement period and at the end of the sordy. Detailed brood assessments included investigation of the fair of more than 200 individually marked cells in each repricate of each treatment group in both studies and were performed on several occasions throughout the studies, covering an entire brood cycles hone bees. Differences between test item and control were only observed in one out of the two studies.

Differences between test item and control were only observed in one out of the two studies. In which is a slight but statistically significant increase was observed in adult mortality on day 14 after application and a slight but statistically significant decrease in flight intensity was observed on the application day and two days after application, and for the mean over the entire observation period. These detects were either transient of so ratio in nature that they are not seen as biologically relevant. When summarized, in both studies it was found that the application of Isoflucypram EC 0 at the rate of 75 g.a.s./ha under tunnel conditions to the full flowering and highly bee attractive surrogate crop hacela tanacetifota generally did not cause any adverse effects on individual broad development (broad termination rate, brood index, compensation index), adult and larval/pupal survival, foraging activity as well as on general colony development (brood status, colony strength and condition) in the test item treatment groups when compared to the respective parallel running controls.

To further investigate exposure of honeybee and honeybee colonies under more realistic worst-case conditions two higher, tier semi-field honeybee studies were conducted following the guideline EPPO 170 (4) with focus on mortality, foraging activity and general colony development. Under these forced/confined exposure conditions the representative formulation Isoflucypram EC 50 was applied at 75 g cs./ha are tunnels to the full flowering and highly bee attractive surrogate crop *Phacelia tanacetifolia*. In the two semi-field (tunnel) tests conducted by \$\frac{1}{2}\$, \$\fr

behaviour. Mortality assessments were continued along with behaviour around the hive during the post-exposure observation period. Colony assessments (colony strength, brood area, food stores) were made before and after the confinement period and at the end of the study.

Few differences between test item and control were detected in these two studies. In the study by ; 2017; M-606834-01-1 a slight but statistically significant increase was observed in pairwise comparisons in adult mortality on 3 individual days. In the study by M-607771-01-1 a slight but statistically significant increase was observed in pairwise comparisons in adult mortality on the day of application. Both detects were transient and so minor in nature that they are not seen as biologically relevant. In sum in both studies it was found that the application of Isoflucypram EC 50 at the rate of 75 g a.s./ha under tunnel conditions the full flowering and highly bee attractive surrogate crop *Phacelia tanacetifolia* did not cause any adverse effects of adult and 6 larval/pupal survival, foraging activity as well as on general colony development brood status. Colony strength and condition) in the test item treatment groups when compared to the respective parallel running controls.

Conclusion

Overall, it can be concluded that Isoflucypram EC 50, when applied at the maximum application rate of 1.5 L product/ha (75 g a.s./ha) even during the Howering period of a bee-attractive crop, does not pose an unacceptable risk to honeybees and honeybee colonies so that it can be safely assumed that an application in cereals will result in safe use of the product when applied as recommended,

CP 10.3.1.1.1

2006; M-521280-01-1 Report:

Title: BCS-CN88460 EC 50 (50 0 g/L); Effects (acute contact and oral) on honey bees (Apis

noelliferation) in the laboratory - Final report -

Report No. 113451935 Document No.:

% US E A OCSPP 850.3020, 850.supp. Guideline(s):

Guideline deviation **GLP/GEP:**

Objective

The purpose of this study was to determine the coute contact and oral toxicity of BCS-CN88460 EC 50 G to the honey bee (A. mellifera L.) if the laboratory. Mortality of the bees was used as the toxic endpoint. Sublethal effects, such as changes in behaviour, were also assessed.

Material and methods:

Test item: CS-CN88469 EC 50 (50 g/L): 50.46 g/L, 5.18% w/w; supplier batch no.: 2016-001002, Specification Nov. 102000031062, Sample Description: TOX20246-00.

Test organism female worker honeybees (Apis mellifera), obtained from a healthy and queen-right colony, breed by IBACON

Under laboratory conditions Apis mellifera 30 worker bees per treatment level were exposed for 96 hours to doses of 80.0, 36.4, 16.5, 7.5, 3.4 and 1.6 µg a.s. per bee by topical application (contact dose response test) and 30 worker bees per treatment level were exposed for 72 hours to doses of 90.7, 81.1, 39.8, 19.9 and 9.1 µg a.s. per bee by feeding (oral dose response test, value based on the actual

intake of the test item). Due to increasing mortality between 24 and 48 hours both contact and oral test were prolonged for further 24 hours up to 72 hours. Additionally, the contact test was prolonged up to 96 hours because of increasing mortality between 48 and 72 hours.

Furthermore, each test consisted of a control and a reference item group. In the contact test, tap water containing 0.5% Adhaesit was used as control. In the oral test a 50 % w/v sucrose solution was used as control. In both tests Perfekthion EC (active ingredient 420.3 g/L dimethoate, Batch no.: FRF 001226) was used as toxic standard. Each treatment group consisted out of 3 replicate (test units) with 10 bees per replicate. Test units were stainless steel cages with 8 cm × 6 cm × 4 cm (length × height × with). The tests were conducted in darkness, temperature was 23.8 - 25.4° and relative humidity was between 59.2 and 64.1%. Biological observations, including mortality and behavioural charges were recorded 4, 24, 48, 72 and 96 h after application in the contact the and 4, 24, 48 and 72 h after application in the oral test.

The software used to perform the statistical analysis was ToxRat Professional.

Behav. abnorm. = Behavioural abnormatities, Water = 002/water freated control

Oral Test:

The oral toxicity test was prolonged for further 24 hours up to 72 frours one to increasing mortality between 24/48 hours. The maximum nominal doce levels of the test item (300.0, 90.9 and 41.3 μg a.s./bee) could not be achieved because the bees did not ingest the full volume of treated sugar solution even when offered over a period of six hours. Actual oral doses of 90.7, 81.1, 39.8, 19.9 and 9.1 μg a.s./bee resulted in dose dependent mortality of 100%, 40.9 13.3 % 3 and 3.3 % at the end of the test (72 hours after application). Also 3.3 % mortality occurred in the control group (sucrose 50 % w/v solution $\frac{1}{2}$ 00 g sucrose L tap water).

Conclusion:

The toxicity of BCS-CN88460 EC 50 (50,4 g/L) was tested in both, an acute contact and are acute or al toxicity test on honeybees. The contact LD₅₀ values (24, 48, 22 and 96 h) were deformined to be \$6.8, 25.7, 17.6 and 14.1 µg a.s./bee, respectively. The oral LDs values (24, 48 and 72 h) were determined to be 74.8, 69.1 and 69.1 µg a.s./bee@espectively.

The NOED (96 h) was 3.4 µg a.s. bee in the contact toxicit a.s./bee in the oral toxicity test.

Acute contact toxicity to bee **CP 10.3.1.1.2**

Please refer to CP 10.3 1.1.1

Chronic toxicity to bees **CP 10.3.1.2**

A 10-day chronic mal toxicity study was conflucted with formula ded isoflucypram (SC 200). The corresponding summary is filed in MCA Section 8, Point 8.2.1.2.

Effects on winey bee development and other honey bee life stages **CP 10.3.1.3**

A repeated hopeybee larvae feeding study was conducted with isoflucypram tech. The corresponding summary is foed under MCA Section 8, Point

Sub-lethal effects CP 10,3.1.4

There is no particular study design / test guideline to assess "sub-lethal effects" in honeybees. However, in each laboratory study is well as in any higher-tier study, sub-lethal effects, if occurring, med de la contraction de la co are described and reported

CP 10.3.1.5 Cage and tunnel tests

Honeybee semi-field studies with focus on brood development (OECD GD 75) have been conducted with Isoflucypram EC 50 and are summarised below.

; 2016; M-5493&°°01-1 Report: KCP 10.3.1.5/01;

Study on the effect of BCS-CN88460 EC 50 G (50 g/L) on honey bees Title:

L.) under semi-field conditions

P15019 Report No.: Document No.: M-549363-01-1

OEPP/EPPO (2010): Guideline for the efficacy evaluation of plant protection products - Side effects on hone bees. OEPP/EPPO, PP 1/170(2) update 2010(2) Guideline(s):

313 - 319

OECD No. 75, Guidance Document on the Honey Bee (Apris methera La) Broods Test under Semi-Field Conditions No. 75, ENV/JM/M®NO(2005)22

Guideline deviation(s): **GLP/GEP:** ves

Objective:

The purpose of the study was to investigate potential side effects of a soray application of BCS-CN88460 EC 50 on the honeybee (April mellifera L) under semi-field conditions by following the OECD Guidance Document No. 35 (2007), with methodological improvements by the AG Bienenschutz (PISTORIUS et al., 2012).

Material and methods:

Test item: BCS-CN \$\frac{3}{4}60 \ EC 50 \ (50 \ g\tau): B(\frac{3}{5}-CN \frac{3}{5}\)460; 5.12 % w/w (analytical); supplier batch No: 2015-000526 Sample Description FAR01848 00; Specification No: 102000029179; density: 0.969 g/mL.

Test species were honeybees (Apis mellifera L., Hymonoptera, Insecta); small honeybee colonies containing 6000 bees each and 300 5 brood combs with brood in alk stages that did not display clinical symptoms of disease and were he a quantight state. The test was conducted in Junnel tents in order to assess, potential side effects of the product

BCS-CN88460 EC 50 G 50 g 60 on boneybee colonies ander semi-field conditions. A plot of Phacelia tanacetifolia with an effective crop area of Ca. 85 m² (2 × 42.5 m²) was prepared for each tunnel (21 m long, 5.5 m wide and 2.5 m high) and each plot constituted one replicate. For each treatment group (control, test item and reference item), 4 funnels/replicates were set up, resulting in 12 tunnels in total. Per tunnel one boneylee colony was used. The bee colonies were placed into the tunnels with Phacelia (BBCH) 60) six days before application. After the exposure period all bee colonies including dead-bee waps were removed from the study field and placed at a monitoring

Applications of the test item BCS-CN88460 E 50 G (50 g/L), control and reference item (Insegar 25 WG, 250 g/kg fenoxycarb) were conducted by spraying the whole area of plants within the tunnel during full bee flight and at full flowering of the crop (BBCH 65). Control tunnels were sprayed with water (400, Tha), test item tunnels received 75 g a.s. in 400 L tap water/ha (corresponding to 1.512 mL product/ha) and reference item tunnels received 300 g a.s. in 400 L tap water/ha (corresponding to nominal 1200 g Insegar/ha).

The following endpoints were assessed:

- Mortality assessment: Dead worker bees, larvae, pupae and drones were assessed in dead-bee traps and on non-woven sheets.
- Flight activity: Numbers of bees that were both foraging on flowering plants and flying around the crop were recorded.
- Behavioural abnormalities of the bees were recorded.

- Colony conditions (estimation of bees, brood, pollen and nectar) assessments were conducted.
- The development of bee brood (ontogenesis of eggs) was evaluated for appropriate amount of eggs (> 200) from each colony.

GLP-validated linear mixed effect models (lme) were used to interpret and evaluate potential treatment-related effects of the test item on the development of honeybee colonies. ANOVA was used to compare fitted models and thus detect the ability of the factors and interactions to explain the encountered variance.

Findings:

Mortality

There was no significant difference (p >0.05) in the mean worker bee and pipal/laval mortality between the test item and the control. Mean worker bee mortality in dead-bee traps was comparable between all treatment groups during the pre-exposure, exposure and post-exposure period. There was a statistical significant difference between the mortality of immature stages (mainly pipae)

in colonies that were exposed to the reference item ($\sqrt{0.001}$). This was consistent with the expected effect of the reference substance "Insegar" and demonstrated that the foraging activities were sufficient to instigate a high level of exposure to the treatments in the bees and their brood.

Flight activity

Overall daily mean foraging activity observed before application was similar in all treatments with 18, 17 and 15 bees in control, test item and reference item. During the exposure phase on average 15, 12 and 10 bees were recorded for control test item and reference item, respectively. No statistically significant differences were observed between control and test item (p > 0.05) while a reduction (p < 0.05) was observed when comparing control and toxic reference item.

Phase S	Control		T&t item			Reference item		
	Mean	±SD	Mean	± SD	stat.	Mean	± SD	stat.
pre-exposure (DAT-2 to 0/0)	184	© \$4.6	16.7	6.5	>0.05	15.0	2.9	< 0.05
exposure (DAT-2 to 0/0)	14.8	7.1	11.5	7.1	~0.03	10.1	4.5	< 0.03

Behaviour

No acute symptoms of poisoning (e.g. twitching or cramping) were observed after the applications of the test item during daytime full bee flight. Nevertheless intensive cleaning, coordination problems and apathy were noticed in tunnels of both test item and reference item treatments on the day of application.

Colony condition

In general, development of the bees was normal for the seasonal period. One colony in the reference item group (Replicate IV, Colony 05) was found with no eggs present during colony assessments, although the queen was sighted during first condition checks. For this reason, this queeness golony was excluded from data analysis of colony conditions and brood development. Overall the strength of the colonies was similar and within a normal range. The average number of worker bees increased after setup in the tunnels for all treatment groups and there was no statistically significant difference between any of the treatment groups (p >0.05). There was also no statistically significant difference between any of the treatment groups for any brood stage (eggs, open and capped worker brood) or for total brood (p >0.05). The amount of cells containing all brood stages increased in all reatment groups but there was a tendency for a decrease in the amount of capped worker brood for the colonies exposed to the reference item. The storage of nectar and pollen was very similar in the colonies and increased throughout the entire study period. Neither, the test item for the toxic reference item treatment resulted in a statistically significant difference in nectar stors (p >0.05). Dinear mixed effect models could not be used for statistical analysis of pallen stores since the baseline in the control was zero.

Development of honeybee brood in individual cells (Brood Termination, Brood Index and Compensation Index)

The mean brood termination rates (BTR) on BED22 were 34.4%, 43.6% and 71.8% for control, test item and reference item colonies, respectively. The statistical analysis showed no significant difference in the brood termination rates of colonies exposed to the control and test item (p >0.05). In contrast, a statistical agnificant effect on the brood termination rate was detected in the comparison between the control and reference item colonies (p <0.05).

On BFD22, the mean brood indices (BT) for control, test item and reference item colonies were 3.28, 2.82 and 1.41, respectively. On increase in the brood index over time was observed for all treatment groups, indicating normal brood development. The statistical analyses revealed no significant difference in the brood indices of the control and test tem colonies (p > 0.05) but there was a statistical significant difference in this variable between control and reference colonies (p < 0.01).

The mean compensation indices (Cr) for control test item and reference item colonies on BFD22 were 4.10, 3.85 and 3.15, respectively. The compensation index increased during the study in all treatment groups. Similar to the findings for the broad index, there was no statistical significant difference between the control and test item colonies (p > 0.05) but there was a statistical significant difference between control and reference item (p < 0.05).

^{*}Replicate IV was excluded from analysis

Conclusion:

In order to assess potential effect posed by BCS-CN88460 EC 50 G (50 g/L) to honeybees, honeybee colonies were exposed for 7 days under semi-field conditions in tunnels cropped with full flowering of Phacelia (BBCH 65) that received treatment with 75 g BCS-CN88460 in 400 L tap water/ha (corresponding to 1.512 mL product/ha). A control group and a reference group were also established for comparison. No statistically significant adverse effects of the test item on brood development (brood termination rate, brood index and compensation index), adult and pupae survival, the condition of the colonies (e.g. on colony strength, the total amount of brood or food stores) or on light activity were found compared to the control.

Objective:

The purpose of the study was to investigate potential sole effects of a spray application of BCS-CN88460 EC 50 on the honeybee Apis mellifera L.) under semi-field conditions by following the OECD Guidance Socurient No. 75 (2007), with methodological improvements by the AG Bienenschutz (PISTORIUS et al., 2012).

Material and methods:

Test item BCS-CN88460 EC 50 G 50 g/L). BCS-CN88460: $\sqrt{18}$ % w/w (analytical); batch ID: 2016-001002; Sample Description *TOX20246600; Specification No.: 102000031262; density:

Test species: Honey bees (Apis mellifera L.; Homenoptera, Insecta). The hives contained only 3445 to 7150 bees per colony at the start of the test on 19 July 2016 Single box colonies with 10 combs and one queen were used. The colories were as homogeneous as possible. Sister queens originated from one breeding line in order to guarantee uniform beganateria in all treatment groups.

The study design comprised one treatment group Type treated with the test item, one treatment group R, treated with the reference item and one treatment group C, treated with tap water, each with four replicates. Applications were made at dull-flowering (BBCH 65) while honeybees were actively foraging on the crop.

The test item B&S-CN88460 &C 50 was applied at a mean rate of 78.9 g a.s./ha. The envisaged target rate was 75 g. s./ha. Tap water was applied in the treatment group C. Insegar was applied at a target rate of 1200 g product/hain the reference item group (corresponding to 300 g fenoxycarb/ha). The spray volume was 400 Iona in all treatment groups.

The initial mean colony sizes per treatment group were in the range of 4501 to 6023 bees. The honeybees remained in the tunnels for 12 days and colonies were assessed twice during the confined period and seven times afterwards.

The following endpoints were assessed:

- Total and mean number of dead bees on the linen sheets in tunnels, in the dead bee traps and in the dead bee bottoms before as well as after the start of exposure in T and the application in C and R, respectively.
- Flight intensity (mean number of forager bees/m² Phacelia tanacetifolia) before as well as after the start of exposure in T and the application in C and R, respectively.
- Behaviour of the bees in the crop and around the hive.
- Condition of the colonies (colony strength and area of the different brood stages and food storage per colony and assessment date).
- Development of the bee brood assessed in individual brood cells. For this particular assessment, between 229 and 266 individually marked cells per colony were selected.

 Findings:

Mortality

Throughout the study (before and following exposure) and especial on the application day, no increases of the adult honeybee mortality were bound by the treatment groups T of R when tested against C, indicating no effect of the test item. A statistically significant difference between C and T was found on 14DAA but this was only minor in nature and not related to the treatment.

During the whole study no dead largae were recorded at any hive, heremafter before to as the "pupal mortality". No statistically signiffcant differences were found between the reatment groups T and C regarding larval/pupal mortality (dead larvae/pupae folony day), nother on any Individual day of the pre- or post-application period, nor if calculated over the periods in the tunnels Defore exposure (4DBA to 0DBA), in the tunnels after application unto relocation to the monitoring site (0DAA to 7DAA), at the monitoring site (8DAA 6 26DAA) and the whole exposure period from application to end of the study at the monitoring site (0DA) to 26 (AA).

In the treatment grown R a strong effect of the toxic reference item was detected by statistically significant higher Supal mortality rates in R on 11, 92, 13, 14, 15, 16, 97 and 24DAA. The pupal mortality rates in R were also statistically significant higher it calculated over the periods at the monitoring size (8DAA to 26DAA C: 12 and N: 16 dead pupae/hive/ day) and over the whole period after application (0DAA to 26DAA, C: 13 and 2: 11.7 dead pupae/hive/day).

As increased pupal mortality starting at about 100AA s a typical and well known effect of the reference item, the increased supal mortality rates refer to a strong toxic effect of the reference item. The observation of pupae with malformations (white eyes) on 8, 9, 11, 13, 14, 15, 17, 18, 22 and 25DAA confirm this observation of a strong toxic reference tem effect.

^{* =} statistically significant higher than control group

Flight activity

The mean flight activity over the period before application was similar in all treatment groups, with no statistically significant differences.

After application on the application day (0DAA), the flight activity in the treatment group statistically significantly lower than the mean flight activity in the control C (7)14.7, C: 21.7 Porager bees/m²; Student's t-test, method pooled, left-sided, $\alpha = 0.05$). On the following day (1DAA) there was already no statistically significant difference between the flight activity in T and Cott. 2027, C: 20.5 forager bees/m²). A small but statistically significant difference was found again on 2Do A (T.) 21.6, C: 26.5 forager bees/m²) but on all following days until 7DAA no statistically significant differences were found between the test item treatment group T and the control C.

Over the exposure period in the tunnels (0DAA to DAA) the difference between the mean highly activity in T and C was statistically significant (T: 18.2, C: 20.7 torager bees/nc). The difference was only 2.5 bees/m² which is minor in nature and therefore biologically negligible. Therefore, no adverse effect of the test item treatment on honeybee flight activity could be discerned.

Behaviour of the bees

No adverse effect of the test item treatment on proncybee below iour could be

Strength of the color

The overall development of colony strength of all froatment groups showed fluctuations in a typical and normal range. The colony strength values of the test item group were on approximately the same level during the entire study compared the corresponding values of the control group. Therefore, no test-item related adverse effects on colony strength were observed.

The mean amount of brood in the colonies sum of cells containing eggs, larvae and pupae) was assessed. Overally on the level of whole colonies, hone bee brood development in the test item treatment group, T as not affected, when compared to the control.

Development of the food storage area

The mean amount of food stores in the colonies (sum of cells containing nectar and pollen) was assessed. All colonies were well provided design the course of the study and there was no lack of pollen or nectar in any colony of any assessment date. Except in treatment group R, where a decline in mean colony strength and food storage are at the end of the first brood cycle (21DAA) was recorded. No test-item elated adverse effects on the development of the food storage area were observed.

Development of honeybeer brood in individual cells (Brood Termination, Brood Index and Compensation Index

In the control group C. Successful development was observed in the majority of the marked brood cells, indicating a healthy development of brood. The mean termination rate at the end of the observation period (BFD+22) was 12.70 %.

In the reference item treatment group R, the mean values of the brood and compensation indices were not statistically significantly lower than those observed in the control. The brood termination rate in R

^{* =} statistically significant lower than nontrol group

Document MCP – Section 10: Ecotoxicological studies Isoflucypram EC 50 (50 g/L)

was 38.56 %. However, adverse reference item effects were documented by high pupal mortality rates and malformations of the pupae in the typical period from 10 days after application.

In the test item treatment group T the brood and compensation indices were comparable to those in the control on all assessment dates after BFD 0. The mean termination rate of 9.30 % was not statistically significantly different to the control.

Conclusion:

BCS-CN88460 EC 50 was applied at a target rate corresponding to 75 g a.s. fra at full-flowering *Phacelia tanacetifolia* during tioneybee foraging activity. The effects on honeybee colonies under confined conditions considering mortality flight intensity, behaviour, colony strength, amount of brood and brood cell development were evaluated.

No test-item related adverse effects on larval pupal and adult worker bee mortality, flight intensity and behaviour were observed over the entire test pood.

The effect of the toxocity of the reference tem was clearly detected by increased pupal mortality rates and the occurrence of pupale with malformations, reported in the treatment group R.

The quantitative assessments of broad development in individually marked cells containing eggs did not result in statistically significant offerences on honeyoee broad development.

No test-item related deverse effects on colony strength mean number of bees per colony), amount of brood (mean number of sells covered with the different types of brood) or on the development of the food storage area were observed.

Honeybee semi-field studies with focus on colony development have been conducted with Isoflucypram EC 30 and are summarised in the following

Report: \$\times KCP \text{ fQ.} 3.1,5/03; \qquad ; 2017; M-606834-01-1

Title: Isoffucypram EC 50 G: Towcity testing on honey bees (Apis mellifera L.) under semi-

field conditions in Germany - Tunnel test

Report No.: 122701037

Document No.: 4 M-606834-0 1

Guideline(s): OFP/EPPO No. 170 (4)(2010)
Regulation (EC) 00. 1107/2009

Directive 2003-01 (Canada/PMRA) US RPA OCSPP Not Applicable

Guideline deviation(s) None GLANGEP:

Objective:

The purpose of the study was to investigate potential side effects of a spray application of Isoflucypram EC 50 on the honeybee (Apis mellifera L.) under semi-field conditions in German by following OEPP/EPPO Guideline No. 170(4).

Material and methods:

Test item: Isoflucypram EC 50 G (50 g/L): BCS-CN88460: 5.28% w/w (analytical); batch ID 2016-60 001002; Sample Description: TOX20246-01; Specification No.: 102000031262; density 0.975/g/mL Test species: Honeybees (Apis mellifera L.; Hymenopiera, Insecta) Colonies with 11 combs 4-7 brood combs) and one queen were used. Three days before application the colories consisted of a constant of the colories consisted of a constant of the colories consisted of the colories constant of the colories colories constant of the colories colories constant of the colories constant of the colories colories constant of the colories color mean of 4770 to 6233 honey bees/colony. The colories were produced at the same time with sister queens in order to guarantee uniform bee material in all treatments.

The study design comprised one of three treatment groups in total, one being treated with the test item, one treated with the reference item dimethorate and one treated with the water, each with four replicates (tunnels). Applications were made at full-flowering BBCH 65) while knoneybees were actively foraging on the crop.

The test item Isoflucpyram EC 50 was applied at a target rate of 75 g a.s./ha m 400L water ha in the 4 tunnels (replicates) for biological assessments. Three additional tunnels (replicates) treated with the test item were set up to measure the concentration of sofluctor and nectar after the application. Dimethoate used as reference tem was applied in the 4 replicates at a target rate of 480 g a.s./ha in 400 L water/ha.

Small bee colonies were introduced to the tunnels of days before the application of the test item, the control and the reference item respectively. The confined exposure phase of the honeybees to the control, test item and reference item was days following the application. In the wening of the 7th day after application, all bee colonies were relocated from their respective tunnels and placed in an area with no main flowering, bee attractive crops.

The following engroints were assessed:

- Mortality: 3 days before to 42 days after application
- Foraging activity of the bees: 3 days before to todays after application
- Behavioural abnormalities: 3 days before to a days after application
- Colony assessments including assessments of brood status (food stores, colony strength and hive Findings:

 Mortality

 Mortality

group was 43.2, 3 2 and 42.6 dead bees/colony/day, respectively. This was not statistically significantly different compared to the water control.

The comparison of the daily and the overall mortality values (day 0 to day 7) between the test item treatment and the control group showed no statistical significant difference to the control. Average control mortality of adult bees during the exposure phase (day 0 to day 7 following the application) were 42.6 dead bees/colony/day and 36.8 dead bees/colony/day in the test item group. The average mortality of the Ference item group was 246.1 dead bees/colony/day. From day 0 to day 3 following the application the number of dead bees found in the reference item treatment were statistically significantly increased compared to the control values.

During the period from day 8 to day 21 after treatment the number of dead bees in the test item treatment was low with a mean of 10.9 dead bees per day and colony, which was not statistical significant different to the control (14.6 dead bees/day/colony). On day 18, a mean of 27.8 dead bees was found in the test item group, (vs 12.8 dead bees in the control), which was statistical significant

different to the control. The mean number of 27.8 dead bees/day/colony is comparable to the control values among the phase outside the tunnels and within biological variance.

The overall comparison from day 22 to day 42 showed that the number of dead bees found in the sest item treatment (6.6 dead bees/day/colony) was not statistical significant compared to the number of dead bees found in the control group (5.8 dead bees/day/colony). The pairwise comparison on days 33° - 35 and 40 - 42 displayed a statistical significant difference of the test item group to the control. However, these mean values (26.3 and 9.8 mean dead bees/colony) were lower compared to the spean values in the control group for e.g. days 26 - 28 (37.8 mean dead bees) or day 28 - 31 (323 mean dead bees) bees) so that these statistical detections are seen to be of no biological relevance.

DBA = Days before application, DAA = Days after application

Foraging activity
The mean foraging activity over the period before application (day - 3 to day -1) was comparable in all treatment groups, with no statistically significant differences.

Overall, from day 0 to day 7, mean foraging activities in the test item group were comparable to the control values (16.3 bees/m²/day and 16.8 bees/m²/day respectively), and hus not statistically significantly different. The overall daily mean foraging activity from day 0 to day 7 in the reference item group was 0.1 Sees/m²/day, which was statistically significantly reduced compared to the control group.

DAA = days after application DBA days before application

No behavioural abnormalities occurred in the test from treated group at any assessment day.

The mean number of honey bees per colorly in all treatment groups was similar three days before application and did not differ statistically significantly (mean of 4770 to 6233 per colony). The subsequent development of the colony strength among the colonies in the control and test item treatment proups followed the same pattern. Overall, no adverse effects of the test item on colony strengthand population development have been observed throughout the study.

Development of the brood area

At the beginning of the trial all colonies to be used for the test were similar according to the season. All queens (or eggs) and brood stages (eggs, larvae and closed brood) were found in all colonies as an indication of healthy colonies. Compared to the control, a similar amount of brood could be found during the assessments with no indication of a test item related effect. All colonies exposed to the test

^{* =} Statistically significant Dower than control group

item remained vital with increasing bee numbers and healthy brood. The amount of individual brood stages (eggs, larvae and pupae) present in the colonies of the different treatment groups fluctuated and was alternating higher in the different treatment groups on the different assessment days. There was no indication of any effect of the test item on the condition of the bee colonies.

Analytical findings

The exposure of the honeybees to the test item was confirmed by analytical measurement of the active substance isoflucypram in the spray solution samples taken from the biological assessment turneds TS, and the extra residue tunnels TR. The concentration of isoflucypram in both groups of tunnels was in a comparable range so that it is assumed that the exposure conditions were comparable in all tunnels treated with the test item. In those tunnels allocated to residue determination, honeybees were used as sampling device. The concentration of isoflucypram measured in the collected poller and nectary samples of the day of application and the day after allows for confirmation of the exposure of the bees inside the tunnels.

The following table gives an overview of the concempation of isoflucyprom in the analysed sample materials after application of Isoflucypram E©50 G with 75 g a.s. Wa in 400 L water/ha.

BCS-CN88460

Conclusion:

Isoflucypram EC 50 6 was applied at 75 g a.s. in 400 Lona (1.46 L product/ha) during full flowering of the surrogate crop Phaceta tanacetifolia and with honey bees present.

No effects on mortality of acult and immature coney bees were observed. Foraging activity, behaviour nectar- and collengtorage as well as queen survival was not affected. There was no effect on overall colony development, development of broad and colony strength observed.

Based on the results of this study it can be concluded that Isoflucypram EC 50 G does not adversely affect honey bee behaviour, broad development, colony strength and queen survival when applied at a rate of 75 g a.s. in 400 L/ha (446 L production) under the above described conditions.

Report: KCP 10.3.1.5/04; , A.; 2017; M-607771-01-1

Title: Assessment of side-effects of isoflucypram EC 50 G on the honeybee (Apis mellifærå

Test item: Isoflucypram EC & G (50 g/L) BCS CN88460: 5.28% w/w (analytical); batch ID: 2016-001002; Sample Description: TOX 20246 1; Specification No.: 10200003162; density: 0.975 g/mL. Test species: Honeybees Apis mellifera L.; Dymer optera insecta). Colonies with 6 combs (2 – 5 brood combs) and one queen were used. At the sort of the test colonies size were in the range of 4436 to 9214 bees. The colonies were produced with sister queens in order to guarantee uniform bee material in all treatment groups.

The study design comprised one of three treatment groups in total one being treated with the test item (T), one treated with the reference item dimethoate (R) and one treated with tap water, each with four replicates (tunnels). Applications were made at trill flowering (BBCH 65) and during daily bee flight. The test item Isoflucypram EC 50 was applied at a target rate of 750g a.s./ha in 400 L water/ha in the 4 tunnels (replicates) for biological assessments. Three additional tunnels (replicates) treated with the test item were set up to measure the concentration of isoflutypram in pollen and nectar after the application. Dimetioate used as reference item was applied in the 4 replicates at a target rate of 400 g a.s./ha in 400 L water/ha.

Small bee colonies were introduced to the tunnel 3 days before the application of the test item, the control and the reference Dem respectively. The confined exposure phase of the honeybees to the control, test item and reference them was 7 days following the application. In the evening of the 7th day after application, all bee cologies were relocated from their respective tunnels and placed in an area with no main flowering, becattractive crops.

The following endpoints were assessed:

- Mortality: 3 days before to 43 days after application
- Flight intensity: 3 days before to 7 day Cafter application
- Behavioural abnormalities: 3 days before to 7 days after application
- Condition of the colonies: Number of bees (colony strength) and development of the bee brood and food storage area: A days before to 43 days after application
- Results of esidu@analysis

Findings:

Mortality

During the pre-application period (3DBA to 0DBA), the mean daily honey bee mortality was \$0.0, 38.5 and 33.9 dead honey bees/colony/day in the treatment groups C, T and R, respectively. No statistically significantly different values of mortality compared to the control were observed in this period.

During the exposure periods inside the tunnels (0DAA to 7DAA), the mean daily mortality values were 14.8 and 24.1 honey bees/colony/day in the treatment groups C and T, respectively. The mean daily mortality values were approximately on the same level in the treatment groups C and T throughout this period and no statistically significant higher values compared to the control group were found except for 0DAA. On the day of application mortality in T was statistically significantly higher compared to the control. However, this statistical significance was not considered to be of any biological relevance since the mean mortality rates for the post application period in C and T were on the same level. This conclusion is supported by the fact that no statistically significantly higher values compared to the control group were observed when calculated for single observation days during the post-application period. During the entire observation period after application (0DAA to 43DAA), the mean daily mortality was 3.7 and 5.2 dead honey bees colony/day in the treatment groups C and T, respectively. During the monitoring period after removal of the colonies from the tunnels (8DAA to 43DAA), the mean daily mortality was 1.2 and 1 dead honey bees colony day in the treatment groups C and T, respectively.

The application of the reference item in treatment R had a clear effect on honey bee mortality. During the post-application period (ODAA to DAA), mortality was in the range from 51.0 to 890.5 dead honey bees/colony/day (mean: 307.2 dead honey bees/day) compared to 8.3 to 2.3 dead honey bees/colony/day (mean: 14.8 dead honey bees/colony/day) in the control. These differences were statistically significant from ODAA to ODAA, for the mean post-application mortality (0DAA to 7DAA) and for the entire observation period after application (DDAA to 43DAA). Elevated, but not statistically significantly higher values were observed an 7DAA. During the monitoring period after removal of the colonies from the connels (8DAA to 43DAA), the mean daily mortality was 1.2 and 7.6 dead honey bees colony/day in the treatment groups C and R respectively, and no statistically significant higher values compared to the control group were found.

Overall, no adverse effects on mortality of honey bees were found for test item treatment group T, except for the day of application (0DAM) with a statistically significantly higher value compared to the control. In the reference from treatment group R a clear impact on honey bee mortality was observed after the application.

DBA Days before application DAA = Days after application

* Statistically significantly higher compared to the control

Flight intensity

Flight intensity was on a comparable level in all treatment groups during the pre-application period (3DBA to 0DBA); indicating similarly intense foraging on the crop. The mean flight intensity was 21.5, 130 and 6.3 forager bees/m² in the treatment groups C, T and R, respectively. A statistically significantly different value in T compared to the control group was observed directly before the application on 0DBA. However, this statistical significance was not considered to be of any biological relevance since the mean flight intensities for the pre- and post-application period in C and T were on the same level (for detailed values see further below). This conclusion is supported by the fact that no statistically significantly lower values compared to the control group were observed when calculated for single observation days during the post-application period.

During the exposure periods inside the tunnels (0DAA to 7DAA), the mean flight intensity was 28.4 and 27.5 forager bees/m² in the treatment groups C and T, respectively. The values for flight intensity were therefore on a similar level in both treatment groups C and T. No significantly lower daily flight intensity values compared to the control group were detected in T during this period.

A statistically significantly different value in R compared to the control group was observed on DBA® and for the mean pre-application period (3DBA to 0DBA). Flight activity after the application in R was significantly reduced from 0DAA to 7DAA as well as for the mean post-application period (0DAA to 7DAA).

ip (B) and by Overall, no adverse effects on flight activity were observed in the test item treatment group (3) a clear impact was observed in the reference item treatment after the application.

DBA = Days before application; DAA = Days after application

Behavioural abnormalities

In the test item group T, normal behavior was observed throughout the assessment period.

Strength of the colonies

The mean number of bees per colony assessed during the first colony assessment on 4DBA was 7217 bees/colony in C (range; 4436 to 8804), 7559 bees colony in treatment, group Torange: 4436 to 8804) and 7388 bees/colons in R (range 4505 to 921). The mean colony strength values of the test item treatment group T followed a pattern of development similar to the control, group C during the entire study. Therefore, no text-item related adverse effects on colony strength were observed and a clear impact in the reference item treatment R after the application was documented.

Development of the brood area

The cologies of the control Cand the reatment group T showed all brood stages (eggs, larvae, capped brood) at all assessment dates during the entire observation period.

Overall, the mean numbers of broad colls of the test item group showed a similar pattern of broad development compared to the corresponding values of the control group during the entire study. Therefore, no test-item related adverse effects on mineybee brood development were observed.

Analytical findings

The exposure of the lieneybees to the test item was confirmed by analytical measurement of the active substance isoflucypram in the spray solution samples taken from the biological assessment tunnels (replicates a-d) and the additional residue tumbels (replicates Te, Tf and Tg). The concentration of isoflucypram in both groups of tunnels was in a comparable range so that it is assumed that the exposure conditions were comparable in all tunnels treated with the test item.

In those turnels allocated to residue differmination, honeybees were used as sampling device. The concentration of sofluctorizing measured in the collected pollen and nectar samples of the day of application (0DAA) and the day after (1DAA) allows for confirmation of the exposure of the bees inside the turnels.

The following table gives an overview of the concentration of isoflucypram in the analysed sample material after application of Isoflucypram EC 50 G with 75 g a.s./ha in 400 L water/ha.

Conclusion:

Isoflucypram EC 50 G was applied at 75 g a.s. in 400 E ha (1.46 L product/ha) during full flowering of the surrogate crop *Phacelia tanaeetifolia* and with honey bees present.

Overall, no biologically relevant adverse effects on protrality and no adverse effects on flight activibehaviour, colony strength, the amount of brood or on the development of the food observed.

Based on the results of this study, it can be concluded that the free thoney bee behaviour, brood development at a first the food of the food CP 10.3.1.6 Field tests with honeybees.

Not necessary when considering the outcome of the risk assessment and the results of the lower-tiered studies.

CP 10.3.2 Effects on non-target arthropods other than bees

The risk assessment was performed according to Guidance Document on Terrestrial Ecotoxicology (SANCO/10329/2002) and to the Guidance Document on regulatory testing and risk assessment procedures for plant protection products with non-target arthropods (ESCORT 2, Candolfied al., 2000²).

A A negative value indicates a lower provality in the treatment than in the control

sign.: statistically significant at 5%-lovel.

n.sign.: not statistically significant.

The exposure Genario is based on the use pattern as given in Table 10- 1. The product Isoflucypram & 50 is intended to be applied in the field once at a maximum rate of 1.5 L product/ha which is equivalent to 75 g isoflucypram/ha. 6

According to ESCORT and the Terrestrial Guidance Document SANCO/10329/2002) the exposure is calculated as:

in-field:

drift factor/VDF \times correction factor / LR₅₀ off-field:

MAF = multiple application factor

Drift factor i.e. 0.027 90th percentage for one application (according to Ganzelmeier)

VDF = Regetation distribution factor = 10

Correction factor = 10 (Tiet) test@Aphideas, Typhlodromus)

5 (Ther 2 test, Aphidius, Diphlodromus, Chrysoperla, Coccinella)

The risk is considered acceptable in the calculated HQ is < 2

Application rates 1.5 Liproduct ha (= 75 g a.s./ha) MAF (multiple application factor) = 1.0 (1 application)

Table 10.3.2-2: Exposure calculation for in-field assessment

Crop / no. of applications	Appl. rate [g a.s./ha]	MAF	in-field PEC _{max} [g a.s./ha]
Cereals / 1	75	1.0	75

Table 10.3.2-3: Exposure calculation for the off-field scenario

Crop / no. of applications	Appl. rate [g a.s./ha]	MAF	Drift [%]	VDF	Correction Tactor	Offifield PEC _{max}
Cereals / 1	75	1.0	2.77	10	L 10	2.08

Risk assessment for non-target arthropods

The risk assessment was performed according to Godance Document on Terrestrial Ecotoxicology (SANCO/10329/2002) and to the Guidance Document on regulatory testing and risk assessment procedures for plant protection products with non-target arthropods (ESCORT 2, Candolfi et al. 2000³).

Tier 1 in-field risk assessment for non-target arthropods

Table 10.3.2-4: Tier 1 in-field risk assessment for non-target arthropods

Crop	Species	₹n-fi ∫ [g	eld PECmx. a.s./hab	LR ₅₀	ANQ A	Trigger
Cereals	A. rhopalosiphi T. pyri		75 0	14/3	\$ 5.3 2.5 &	45 25G

For the standard species, the in-field scenario is above the targer of concern. Therefore, a Tier 2 risk assessment is presented with the two standard species and the two additional species Chrysoperla carnea and Cocinella Septempunctofa.

Table 10.3.2-5: Tier 2 in-field risk assessment for non-target arthropods

Crop		ield PECmax. g axs./ha]		Risk acceptable if:	Refined assessment required?
	A Gopalogiphi		17.8	Effects are <50%	Yes
Cereals	A. pyri		> 2 2.2	Effects are <50%	Yes
	C. carnea 🦃 🎝		×> 75	Effects are <50%	No
. **	C. septempunctata		> 75	Effects are <50%	No

For the standard species A. rhopalosyphi and Typhlodromus pyri at Tier 2, the in-field risk assessment reveals effects 50% at the an-field rate of 75 g a.s./ha. Therefore, further refinements are necessary.

³ Candolf of al.: Guidance Document on regulatory testing and risk assessment procedures for plant protection products with non-target arthropods; ESCORT 2 workshop (European Standard Characteristics Of Non-Target Arthropod Regulatory Testing), Wageningen, NL, March 21-23, 2000, SETAC Europe; SETAC publication August 2001

Refined in-field risk assessment for *Aphidius rhopalosiphi*

An extended aged residue laboratory study was performed with the most sensitive species Aphidius rhopalosiphi. Isoflucypram EC 50 was applied to potted maize plants at a rate of 1.46 L product/ha. An application rate of 1.46 L product/ha is equivalent to 75 g a.s./ha under the conditions of the test. The exposure of the test organisms to fresh residues (0DAT1) resulted in a mortality of 3.0%. No mortality occurred when test organisms were exposed to aged residues (14DATY).

A statistically significant reduction in reproductive success relative to the control of 44.7% was found after exposure to fresh residues (0DAT1). After exposure to aged residues (14DAT1) a reduction in reproduction of 13.8% was observed which was not statistically significantly different to the control. Since effects on mortality and reproduction dropped below 14% after aging of the residues for 14 days it can be concluded that the potential for recovery is given within two weeks after the application. Therefore, no unacceptable effects on non-target art wopods in the in-field area are expected from the intended use of isoflucypram EC 50.

Tier 1 off-field risk assessment for non-target arthropods

Table 10.3.2- 6: Tier 1 off-field risk assessment for fron-target arthropods

Report:

Title: Toxicito to the parasitoid wasp Aphidios rhopalosiphi (Hymenoptera: Braconidae)

@using@laboratory test BCS-@\8846@EC 509/L

Report No.: Document No.:

Guideline(s): EU Directive 9 414/FEC

Regulation (EC) No 0 107/2009 US@PA OCSPP Not Applicable? MEAD-BRIGGS ET ALC (2000)

Guideline deviation(s) GLP/GEP:

Objective:

The objective of this laboratory study was to investigate the lethal toxicity of BCS-CN88460 EC 50 g/L on the parasitoid was p Aphidius rhopalosiphi when exposed on a treated glass surface.

Material and methods:

Test item BCS-CN88460 EC 50, Supplier batch No: 2016-001002, Spec. no: 102000031262, analysed content of active substance isoflucypram: 5.18% w/w (50.46 g/L).

The test item was applied on glass plates at rates of 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha in 200 L deionised water/ha using a calibrated laboratory track sprayer (mean measured application rate: 198 L/ha). The effects of the test item on the parasitoid wasp *Aphidius rhopalosiphi* were compared to those of a deionised water treated control. A reference item (active substance: dimethoate) applied at 0.04 g a.s./ha in 200 L deionised water/ha was included.

Mortality of 60 adult wasps, not older than 48 h at study start (4 replicates with 15 wasp per test group), was assessed 2, 24 and 48 h after exposure (food = feeding solution which consisted of 3 parts of water + 1 part of honey).

The climatic test conditions during the study were 19.5 20.5 °C temperature and 65 - 83% relative humidity. The light / dark cycle was 16:8 h with a light intensity range of 930 - 125 Lux

The LR₅₀ value (lethal rate causing 50% mortality) was calculated by Spearman Karbelymethod. The computer program SAS (Version 9.4) was used to perform the statistical analyses.

Findings:

In this laboratory test the effects of BCS-CN88460 BC 50 get residues on the survival of Aphidius rhopalosiphi were determined at 7.5, 18.3, 23.7, 42.2 and 75.0 g a 8/ha, applied to glass plates. After 48 h of the study 1.7% of the wasps were found dead in the control group. In all est item rates a statistically significant mortality was found (Fisher's Exact test one-weed, or 0.05). In the test item rates of 7.5 and 13.3 g/a.s./ha/a confected mortality of 19.2% and 32.2% occurred, respectively. In all higher test tem rates of 23.7, 42.2 and 75.0 g/a.s./ha, the corrected mortality was 100%.

Title:

Toxicity to the predatory mite Typhlodromus pyri (Acari: Phytoseiidae) using a laboratory test BCS-CN88460 EC 50 g/L

Report No.:

Guideline deviation(s):

Guideline deviation(s CN88460 EC 50 g/L to the productory mite Typhlodromus pyri whom exposed to a treated glass surface.

Material and Methods:

Test item: BCS-CN88460 RC 50, Supplier batch No. 2016 001002, Spect no: 102000031262, analysed content of active substance isoflypyprand 5.18% w/w (30.46 g/L).

The test item was applied onto glass plates at rates of 7.5, 53.3, 26.7, 42.9 and 75.0 g a.s./ha in 200 L deionised water ha using a calibrated laboratory track sprayer mean measured application rate: 189 L/ha). The effects of the test item on the predatory mite Typhlodromal pyri were compared to those of a deionised water treated control. A reference item (active substance: dimethoate) applied at 5.0 g a.s./ha in 200 L deionised water ha was included.

Mortality of 100 predatory mites protons inphs at study start is replicates of 20 individuals per test group), was assessed 4 and 7 days after exposure by counting the number of living and dead mites (food = pollen mature one part birch, one part pine). The number of escaped mites was calculated as

the difference from the total number exposed. The climatic lest conditions during the study were 240 - 25.5 °C temperature and 60 - 72% relative humidity. The light / dark cycle as 16% h with a light intensity range of 119 - 540 Lux.

The LR₅₀ value (lethal rate causing 50% moreality) was calculated by Probit analysis.

The computer program SAS (Version 9.4) was used to perform the statistical analyses.

Findings:

In this laboratory test the effects of BCS-CN88460 EC 50 g/L residues on the survival of the predatory mite Typhle Tromus pyri were determined at the rates of 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha applied to glass cover slides.

The mortality rescaping rate on the control exposure units up to day 7 after treatment was 13.0%.

In the higher test tem rates of 23.7, 42.2 and 75.0 g a.s./ha, a statistically significantly different mortality compared to the control was found (Fisher's Exact test, one-sided). At the lower test item rates of 5.5 and 13.3. g a.s/ha, a corrected mortality of 2.3% and -6.9% has been observed, respectively. At the test item rates of 23.7, 42.2 and 75.0 g a.s./ha, the corrected mortality was 27.6%, 80.5% and 96.6%, respectively.

A summary of the effects observed in this study is given below.

Test item								
Test organism			Typhlodromus pyri

Conclusion:

The LR_{50} was calculated to be 300 g as Tha. The NOCR for mortality was \$\infty\$ 13.3 g a.s./ha. The figures obtained fulfil the validity criteria of the laboratory method for exposure on glass plates (BLÜMEL ET 487, 2000).

CP 10.3.2.2 Extended laboratory testing, aged residue studies with non-target

Report: Q KQD 10.3-2.2/01; M-583441-01-1

Title: Toxicity of the parasitoid wasp ophidius rhopalosiphi (Hymenoptera: Braconidae)

casing an extended laboratory test on barley BCS-CN88460 EC 50 g/L

Report No.: CW16/038 \
Document No.: M.\$33441001-1

Guideline(s): Directive 91/444/EFO; Regulation (EC) No. 1107/2009; US EPA OCSPP not

applicable _____

Guideline deviation(s) none of the control of the c

Objective

The objective of this extended laboratory study was to investigate the lethal and sublethal toxicity of BCS-CNS 460 EC 50 on the parasitoid wasp *Aphidius rhopalosiphi* when exposed on a plant surface.

^{*} Corrected mortality according to SCHNEIDER-@RELLE (1947)

Material and methods:

Test item: BCS-CN88460 EC 50, Supplier batch No: 2016-001002, Spec. no: 102000031262, analysed content of active substance isoflucypram: 5.18% w/w (50.46 g/L).

The test item was applied on barley seedlings (*Hordeum vulgare*) at rates of 7%, 13.3, 23.7, 22.2 and 75.0 g a s /ha in 400 L deignized water/ha and the Co. 75.0 g a.s./ha in 400 L deionised water/ha and the effects on the parasitoid was Aphidius rhopalosiphi were compared to those of a deionised water treated control. A toxic reference (active substance: dimethoate) applied at 4 g a.s./ha was included to indicate the relative susceptibility of the test organisms and the test system.

Mortality of 30 female wasps, not older than 48 h at study start (6 peplicates with group), was assessed 2, 24 and 48 h after exposure.

Repellency of the test item was assessed during the initial 3 h after the release of the females. Eve separate observations were made at 30-minute intervals starting 15, 30 minutes after the introduction of all wasps. An additional repellency assessment for the control and the 13.3, 23.7, 42.2 and 75.0 g a.s./ha rates of the test item was conducted 24 h after the release of the wasps into the exposure units. From the water control and all test item rates, 20 impart ally chosen females per treatment were each transferred to a cylinder containing untreated barley seedlings infested with Rhopedosiphum pade for a period of 24 h. The number of mummies was assessed 11 days later.

The climatic test conditions during the study were 19.0 21.0 C temperature and 3 - 85% relative humidity. The light / dark cycle was 16:8 h with a light intensity range of 524 - 685 Lux in the mortality phase, 2510 - 4370 Lips in the parasidisation phase and 9200 - 15060 Lips in the reproduction phase of the study.

Findings:

In this extended laboratory test the effects of BCS-CN88460 EC 50 residues on the survival of Aphidius rhopalosiphi were determined at 7.5, \$3, 23.7, 42.2 and \$5.0 g a.s./ha, applied to barley seedlings (Hordeum vulgare).

The corrected mortality in all test item rates (7.5, 13.3, 23.7, 42.2 and 15.0 g a.s./ha) was below 7%. All test item rates were not statistically significantly different compared to the control.

Repellent effects of the test tem (settling of the wasps on plants <30%) were observed in the first 3 h after the introduction of the wasp's into the exposure units at the test item rates of 13.3, 23.7, 42.2 and 75.0 g a ha. No further repetent effects were observed after 24th.

Reproduction was assessed for all rates of BC\$CN88460 EC 50, 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha. The reduction in reproductive success relative to the control at the 7.5 and 13.3 g a.s./ha rate was 45.8% and 53.8% At the higher test item rates of 20%, 42.2 and 75.0 g a.s/ha the reproduction was reduced by 77.0%, 62.8% and 6006%, respectively. All test item rates were statistically ed in this study is a significantly different compared to the control.

A summary of the effects observed in this study is given in the following table.

Mean reproduction per tonale in water control ≥ 5 5	31
Number of wasps in the water control producing zero values for reproduction	0

The LR₅₀ was estimated to be 75.0 g a.s./ha/The NOER for mortality was ≥ 75.0 g a.s./ha. The ER₅₀ was calculated to be 17.8 c a.s./ha/The NOER for reproduction was < 7.5 g a.s./ha. The figures obtained fulfill the validity criteria of the extended laboratory method (MEAD-BRIGGS ET AL., 2010).

KCP 10.3.2.2/02; ; 2017; M-608958-01-1 Report:

Title: Toxicity to the predatory mite Typhlodromus pyri (Acari: Phytoseiidae) using a

Objective:

The objective of this extended laboratory study was no investigate the lethal and sublethal toxicity of BCS-CN88460 EC 50 to the predatory mite. Typhlatromus pyri when exposed to treated leaf surfaces.

Waterial and methods:

'est item: BCS-CN88460 EC 50. Supplier barch No. 2016-001902, subject to the predatory mite of the substance isogueypram: 5, 8% w/s; (50 /r)

The objective of this extended laboratory study was no investigate the lethal and sublethal toxicity of BCS-CN88460 EC 50. Supplier barch No. 2016-001902, subject to treated leaf surfaces.

Waterial and methods:

'est item: BCS-CN88460 EC 50. Supplier barch No. 2016-001902, subject to treated leaf surfaces.

The objective of this extended laboratory study was no investigate the lethal and sublethal toxicity of BCS-CN88460 EC 50. Supplier barch No. 2016-001902, subject to treated leaf surfaces. dimethoate) applied at 20.0 ga.s./ha in 200 L deignised water/ha was included.

Mortality of 100 predatory mites, protonymens at story start (5 repricates with 20 individuals per test group), was assessed of day 4 and 7 after exposure by counting the number of living and dead mites (food = pollen mixture, one part birch : one part bine). The number of escaped mites was calculated as the difference from the total number exposed.

The reproduction rate of surviving mites in the control and rest item group was then evaluated on day 7, 10, 12 and 14 after application by counting the total number of offspring (eggs and larvae) produced.

The climatic test conditions during the study were 23.5 - 250 °C temperature and 60 - 72% relative humidity. The hight / dark cycle was \$\infty\$6:8 howith a hight invensity range of 96 - 399 Lux.

Findings:

In this extended laboratory test the effects of BCS CN88460 EC 50 g/L residues on the survival of the predatory mite Typhrodrophus pyvo were determined at the rates of 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha applied to detached bean leaves (*Phasedus vulgaris*).

The mortality / Scaping rate in the control sposure units up to day 7 after application was 11.0%. At the rates of 7.5, 123 and 23.7 g/a.s./ha, no statistically significantly different mortality compared to the control occurred. A spatistically significant mortality was found in the group treated with 42.2 g a.s./ha (Figher's Exact test, one sided, $\alpha = 0.05$). At the highest rate of 75.0 g a.s./ha, no statistically significant morbality was detected.

At the lower rates of 7.5, 13.3 and 23.7 g a.s./ha, the corrected mortality was 6.7%, 9.0% and 4.5%, respective. At the 42.2 a.s./ha rate, a corrected mortality of 19.9% was found. 10.1% corrected mortality were detected at the highest test item rate of 75.0 g a.s./ha.

In the reference item group the corrected mortality was 84.3% on day 7 of the study.

Reproduction was assessed for all rates of BCS-CN88460 EC 50 g/L. At the lower rates of 7.5, 13.3 and 23.7 g a.s./ha, the reduction of reproduction was 44.4%, 31.3% and 19.2%, respectively, which

was statistically significantly different compared to the control (Welch test, one-sided, $\alpha = 0.05$). A reduction of 21.2% was found in the 42.2 g a.s./ha rate which was not statistically significant. At the of 64.0% highest test item rate of 75.0 g a.s./ha, a statistically significant reduction of reproduction of 64.0% was found (Welch test, one-sided, $\alpha = 0.05$).

Title: Toxicity to the green lacewing Chrysoperla carnea (Neuroptera: Chrysopidae) using

an extended laboratory test on bean - BCS-CN88460 EC 50 g/L

Report No.: CW16/039 Document No.: M-601137-01-1

Guideline(s): EU Directive 91/414/EEC

Regulation (EC) No. 1107/2009 US EPA OCSPP Not Applicable VOGT ET AL. (2000) modified CANDOLFI ET AL. (2001)

Guideline deviation(s): none **GLP/GEP:** yes

Objective:

The purpose of this study was to investigate the lethal and subjethal toxicity of BCS-CN\$8460 EC 50 g/L to the green lacewing *Chrysoperla carned* when exposed to treated lear surfaces.

Material and methods:

Test item: BCS-CN88460 EC 50 Supplier batch No. 2016 001002, Spec. no. 002000031262, analysed content of active substance isoflucy pram. 5.18% w/w 50.46 L).

The test item was applied to deteched bean leaves (*Phaseotus vulgaris*) at rates of 7.5, 43.3, 23.7, 42.2 and 75.0 g a.s./ha in 200 L deionised water/ha using a calibrated laboratory track sprayer (mean measured application rate; 195 L/ha). The effects of the test item on the green lacewing *Chrysoperla carnea* were compared to those of a deionised water to ated control. A reference item (active substance: dimethoate applied at 36 g a.s./ha in 200 L deionised water/ha was included to indicate the relative susceptibility of the test organisms and the test system.

The preimaginal mortality of 40 larvae over test group, 2 days old at study start, was assessed till the hatch of the imagines up to 20 days (larvae food UV-strilized eggs of Ephestia kuehniella). The fertility and feed indity of the surviving hatched adults were then evaluated over the period of one week (adult food = artificial diet).

The climate test conditions during the study were 24.5 - 25.5 °Comperature and 69 - 76% relative humidity. The light / dark cycle was 6.8 h with a light intensity range of 1770 - 3585 Lux during the mortality phase and 6.2740 3250 Lux during the reproduction phase of the study.

The computer program SAS (Version 9.4) was used toperform the statistical analyses.

Findings:

In this extended laborator test the effects of BCS-CN88460 EC 50 g/L residues on the survival of the green lacewing *Chrysoperla carnea* wore determined at the rates of 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha applied to detached bean leaves (*Phaseoluc vulgaris*).

No statistically significantly different mortality compared to the control was found (Fisher's Exact test, one orded) in all test item rates with a corrected mortality below 14%.

Reproduction was assessed for all rates of BCS-CN88460 EC 50 g/L. There were no adverse effects of the test item of the reproductive performance. The mean number of eggs/female/day was above the lower limit given as validity criterion for the glass plate method (mean number of eggs/female/day: ≥ 15, mean fatching rate: ≥ 70% according to the historical database of the ring testing group (VOGT ET AL., 2000).

Toxicity to the lady wild beet Coccinella septempunctata (Coleoptera: Coccinellidae) Title:

using an extended aboratory test on bean BCS-CN88460 EC 50 g/L

CW17/000 Report No.3

M-608806-01-P Document No.:

Schmuck et al. (2000) modified Guideline(s):

Candolfiset al. (2001)

none Guideline deviation(s): **GLP/GEP:**

The purpose of this study was to investigate the lethal and sublethal toxicity of BCS-CN88460 EC 50 g/L to the ladybird beetle Coccinella septempunctata when exposed to treated leaf surfaces.

^{*} Corrected mortality according to SCHNEIDER-QUELLI (1947)

Material and methods:

Test item: BCS-CN88460 EC 50, Supplier batch No: 2016-001002, Spec. no: 102000031262, analysed content of active substance isoflucypram: 5.28% w/w (51.45 g/L).

The test item was applied to detached bean leaves (*Phaseolus vulgaris*) at rates of 7.5, 13.3, 23.7, 42.2 and 75.0 g a.s./ha in 200 L deionised water/ha using a calibrated laboratory track sprayer (mean measured application rate: 203 L/ha). The effects of the test item on the ladybird beetle. *Coccinella septempunctata* were compared to those of a deionised water treated control. A reference item factive substance: dimethoate) applied at 12 g a.s./ha in 200 L deionised water/ha was included. The preimaginal mortality of 40 larvae, 4 days old at study start (per test group), was assessed till the hatch of the imagines up to 15 days (food = *Acyrthosiphon pisum*). The reproduction assessment of the surviving hatched adults started one week after the first eggs in the control could be observed. The number of fertile eggs laid per viable female was recorded over a period of two weeks. The climatic test conditions during the study were 23.5 - 27.0 °C temperature and 60 - 35% relative humidity. The light / dark cycle was 16:8 h with a light intensity range of 1890 3470 lux during the study. The computer program SAS (Version 9.4) was used to perform the statistical analyses.

Findings:

In this extended laboratory study the offects of BCS-CNSS460 EC 50 L residues of the survival of the ladybird beetle *Coccinella septempunctuta* were determined at the oates of 7.5, 15.3, 23.7, 42.2 and 75 g a.s./ha applied to detached bean leaves (*Phaseolys vulgos*).

All test item rates of BCS-CN 88460 FC 50 g/L had no or only light influence on the preimaginal mortality.

Reproduction was assessed for all rates of BCS_CN88460 EC 50 g/F. There were no adverse effects of the test item rates of 7.5, 73.3, 23.7, 42.2 and 5 g as //ha of the reproductive performance. The mean number of fertile eggs/per ferhale and/day was above the lower limit given as validity criterion. Since the reproductive performance was within the range of the historical data base for control beetles (≥ 2 fertile eggs per ferhale and day. So HMUCK ET AL. 2000) this parameter is considered as not affected at all test item rates.

Test item Test organism Exposure on		BCS-CN88460 EC 50 g/L Coccinella septempunctata Detached bean leaves										
									Preimaginal mortality [%]			Reproduction

Document MCP – Section 10: Ecotoxicological studies Isoflucypram EC 50 (50 g/L)

Report: KCP 10.3.2.2/05; , D.; 2017; M-600692-01-1

Title: Toxicity to the parasitoid wasp Aphidius rhopalosiphi in an extended laboratory test

with aged residues on maize Isoflucypram EC 50 g/L

Report No.: CW17/014 Document No.: M-600692-01-1

Guideline(s): EU Directive 91/414/EEC

Regulation (EC) No. 1107/2009 US EPA OCSPP Not Applicable

MEAD-BRIGGS ET AL. (2010) modified

CANDOLFI ET AL. (2001)

Guideline deviation(s): none **GLP/GEP:** yes

Objective:

The objective of this study was to investigate the lethal and subletted toxicity of Coflucypram EC 50 to the parasitoid wasp Aphidius rhopalosiphi when suposed to fresh and aged residues of the test item on maize.

Material and methods:

Test item: BCS-CN88460 EC 56 Supprier barch No. 2016-001002, Spec. no. 10200031262 analysed content of active substance isoflucyprom: 5.28% w/s/(51.49 g/L)

The test item was applied on potted majze plants (Zea mays at a rate of 75 g os./ha in 400 L deionised water/ha using a calibrated plot sprayer (mean measured application rate: 393 L/ha). The control plants were treated with deionised water in the same way as the test item. A reference item (active substance: dimethoated was applied at 4 g a.s./ra in 400 L deionised water/ha on the application day of the test item on potted majze plants as well. For the further exposure dates the reference item was applied directly on retached majze leaves (with 4 g a.s./ha in 400 L deionised water/ha).

Aging of the spray deposits of the jest item on the potted make plants took place under semi-field conditions with UV permeable rain protection during the whole study. Two bioassays were performed, the first stated on the application day to DATO = 0 days after treatment) and the last two weeks later (2DAT).

Parasitoid wasps (Aphidius phopalosiphi) were exposed to these residues on the treated leaf surfaces.

Mortality of 30 comale wasps not other than 48 h at study start (6 replicates with 5 wasps per test group), was assessed 3, 24 and 48 to after xposore in both bioassays (food = 10% fructose solution sprayed onto test plants).

Repellence of the test item was assessed during the initial 3 h after the release of the females. Five separate observations were made at 30-minute intervals starting 15 - 30 minutes after the introduction of all wasps.

The reproductive performance was assessed in both bioassays. For this 20 impartially chosen females from the water control and the test item group were each transferred to a cylinder containing untreated barley seedlings infested with *Rhopaloaphum padi* for a period of 24 h. The number of mummies (parasitized aphids in which wasp pupae subsequently develop) was assessed 12 days later in the first and 10 days later in the second bioassay.

The effects of the test item on the test organisms were compared to those of the control with suitable statistical procedures using the computer program SAS (Version 9.4).

Findings:

In this extended laboratory test the effects of Isoflucypram EC 50 g/L residues (fresh and aged under semi-field conditions, with rain protection during the whole study) on the parasitoid wasp *Aphilius rhopalosiphi* were determined after an application of 75 g a.s./ha onto maize plants (*Zea mays*).

The bioassays were started on the application day of the test item (0DAT1) and 14 days later (14DAT1). These bioassays resulted for the test item group in 3.3% mortality in the first and no mortality in the second bioassay. All data for the test item group were not statistically significantly different compared to the control group (Fisher's Exact test one-sided).

In both bioassays the exposure to the reference item resulted in 100% mortality of the test organism after 48 h of exposure.

In the first bioassay a mean of 54.0% of the wasps cettled on the leaves in the control group within the first 3 h after the release of the females. In the test item group a mean of 2.8% of the wasps were found on the leaves, indicating a statistically significant repellent effect. Dunnet test, one-sided). In the reference item group 50.2% of the wasps settled on the leaves.

In the second bioassay a mean of 54.2% of the wasps settled on the leaves in the control group within the first 3 h; this compared to 46.7% in the test item group and was not statistically significantly different (Wilcoxon test, one-sided). On the reference item group 37.3% of the wasps were found on the leaves.

the leaves.

The reproduction was assessed in both bioassays. A statistically significant reduction in reproductive The reproduction was assessed in both bioassays. A statistically significant reduction in reproductive success relative to the control of 44.7% was found in the first bioassay (one-way ANOVA, Dunnett test, one-sided). In the second bioassay a reduction in reproduction of 13.8% was observed which was not statistically significantly different (Dunnettest, one-sided). success relative to the control of 44.7% was found in the first broassay (one-way ADOVA, Dunnett

CP 10.4.1.1 Earthworms sub-lethal effects

Report: KCP 10.4.1.1/01; ; 2016; M-574897-01-1

Title: BCS-CN88460 EC 50 G: Effects on survival, growth and reproduction of the

earthworm Eisenia fetida tested in artificial soil

Report No.: E 312 04951-5 Document No.: M-574897-01-1

Guideline(s): EU Directive 91/414/EEC; Regulation (EC) No. 1107/2009; US EPA OCSPA Not

Applicable

Guideline deviation(s): minor deviations

GLP/GEP: ves

Objective:

The purpose of this study was to assess the effect of BCS-CN88460/EC 50 G (Isoflucypram EC 50) on survival and reproduction of the earthworm *Eisenja fetida* in adjficial soil. The test was performed according to the International Standard ISO 11268-2 (1998) and OECH 222 (April 13, 2004).

Material and methods:

Test item: BCS-CN88460 EC 50 6; 5.18 % www equivalents 50.46 g/L: Supplier batch code: 2016-001002; Spec. no.: 102000031262; sample description: TQX2024600; density: 974 g/mL.

Adult Eisenia fetida, approx. 7 months old, 8 × 10 earthworms for the control group and 4 x 10 animals per test concentration of the treatment groups, were exposed to control and treatment. Non-reusable plastic boxes (length x width x height ca. 16.5 cm × 12 cm × 6 cm, area approximately 200 cm²) were used as test vessels. Normal test concentrations of 00, 18×32, 56, 100, 180, 320 and 560 mg test item/kg dry weight artificial soil were mixed into the artificial soil. During the study they were fed with animal minure. A temperature of 20 ± 2 and a light regime of 400 – 800 lux, 16 h light and 8 h dark during the conduct of the study were applied. The artificial soil was prepared according to the guideline with the following constituents (percentage distribution on dry weight basis): 70% fine quartz sand; 10% Sphagnum peat, air dried and finery ground, 26% Kaolin clay. Each test vessel contained in amount of approximately 500 g artificial soil dry weight) to obtain a depth of approximately 5 cm. soil in the test vessels. After 28 days the number of surviving adult earthworms and their weight alteration was determined. Therefore they were removed from the artificial soil. After further 28 days, the number of After was determined.

Findings:

Biologica@results:

Effects on mortality and growth of the adults after an exposure period of 28 days and the number of offspring per test vessel after 56 days are shown in the following table (values in this table are rounded values). After 28 days of exposure, no mortality in the control group was observed. No statistically significant effects up to and including 560 mg test item/kg dry weight artificial soil (the highest test concentration) were observed (Fisher's exact binominal test, one-sided greater,. $\alpha = 0.05$). No statistically significant effects for the growth relative to the control were observed in any test item concentration (William's t-test) two-sided, $\alpha = 0.05$).

No statistically significant differences concerning the number of juveniles relative to the control were observed in any tear item concentration up to and including 560 mg test item /kg dry weight artificial soil (William's t-test, one-sided smaller, $\alpha = 0.05$).

Due to the lack of a clear concentration-response relationship no reliable $EC_{10/20}$ calculation was possible.

^{* (}Fisher's Exact Binormal Test one-sided greater, $\alpha = 0.05$), + significant, - not significant

Experimental conditions:
The pH values measured in the control and the treatments ranged from 5.87 to 6.14 at test start and from 6.03 to 6.14 at test end. The vater content during the whole study was between 49.14 to 60.82 of WHC max.

Validity criteria:
All validity criteria were met.

Validity criteria according to OECD 222 (13 April 2004)	Obtained in this study
Mortality of the adults in the control should be $\leq 10\%$	0 %
Number of juveniles (earthworms per control vessel) should be ≥ 30	103 to 197
Coefficient of variation of reproduction in the control should be $\leq 30 \%$	24.8 %

^{** (}William's t-test, two-sided, $\alpha=0$ 0), += significant, -= not significant *** (William's t-test, one-sided smaller, $\alpha=0.05$), *significant, - not significant n.d. – could not be determined, secrobservations and conclusions.

Reference test:

The most recent toxic standard reference test, with the reference test item mixed into the artificial soil, was performed from August 25 to November 19, 2015 (Report No. kra-Rg-R-Ref 26/15; NON-GLP). Effects on mortality and growth of the adults after an exposure period of 28 days and the number of offspring after 56 days were determined.

No mortality of the adult earthworms was observed 28 days after application. The change of body weight of the adult earthworms of the test concentration of 5.0 mg a.s./ α g dry weight soil was statistically significant reduced in comparison to the control (results of a Williams multiple sequential) t-test, two-sided, $\alpha = 0.05$). The number of juveniles per test vessel of the two highest test concentrations of 2.50 and 5.00 mg a.s./kg dry weight artificial soil were statistically regnificant reduced in comparison to the control (results of a Williams multiple sequential t-test one sided smaller, $\alpha = 0.05$).

According to the guideline significant effects should be observed between 5 and 5 mg a.s./kg dry weight artificial soil.

Thus the results of this reference test indicated that the test system was sensitive to the reference test item.

Conclusion:

Based on the effects observed on mortality growth and reproduction, it is concluded that the overall NOEC for the study is determined to be $\frac{1}{2}$ 560 mg test item/kg dry weight soil. Thus the overall LOEC is determined to be $\frac{1}{2}$ 560 mg test flem/kg dry weight soil. Due to the lack of a clear concentration-response relationship no reliable EC₁₆₀ calculations was possible.

CP 10.4.1.2 Earthworms field studies

In view of the results presented above, no field studies were necessary

CP 10.4.2 Frects on non-target soil meso- and macrofauna (other than carthworms)

The risk assessment (calculation of TER values) was based on the NOEC values calculated from the studies performed with the product, the agrice substance or the metabolite. In case EC₁₀ values were lower than the NOEC and the calculation was reliable they were used for the calculations of TER values.

All TER values clearly exceed the trigger value of sindicating that no unacceptable adverse effects on soil macro-organisms are to be expected from the intended use of Isoflucyprant EC 50 in cereals.

CP 10.4.2.1 Species level testing

Report: KCP 10 4.2.1/01; 2019 M-591834-00-1

Title: BCS ON88460 EC 50 G: Influence on mortality and reproduction of the collembolan

species Folsomia candida Cested in artificial soil

Report No.: E 14 05007-0

Document No.: M-591874-014

Guideline(s): EU Directive 1/414/EEC

Regulation EC) No. 1107/2009 O EPA OCSPP Not Applicable

Guideline deviation(s): none GLP/GEP: ves.

Objective:

The purpose of this study was to assess the effect of BCS-CN88460 EC 50 (Isoflucypram EC 50) on survival and reproduction of the collegebolar species *Folsopiia candida* during an exposure of 28 days in an artificial soil comparing control and treatment.

Material and methods:

BCS-CN88460 EC 50 G (analytical findings: 5,10% w/w BCS-CN88460 (Isoflucypram) equivalent to 50.46 g/L, density 0.974 g/ml (20%), supplier batch no.: 2016-001002, sample description: TOX20246-00, specification no. 102000031202, sample ID: M16001677001)

10 collembolars (10-12 days old) per replicate (8 replicates for the control group and 4 replicates for each treatment group) were exposed to control and treatment. Concentrations of 18, 32, 56, 100, 178, 316, 562 and 1000 mg test item/kg dry weight artificial soil were mixed into the artificial soil. During the study they were fed with granulated dry yeast. A temperature of 20 ± 2 °C and a light regime of 400 - 800 lux 6 h light: 3 darkness during the conduct of the study was applied. The artificial soil was prepared according to the guideline with the following constituents (percentage distribution on dry weight basis): 75% fine quartz sand, 5% Sphagnum peat, air dried and finely ground, 20% Kaolin clay. Mortality and reproduction were determined after 28 days.

The calculations were performed with unbounded values

Observations:

Mortality

In the control group 8.8% of the adult Folsonia capital which is below the allowed maximum of $\leq 20\%$ mortally.

Concerning the mortality of the will test organisms spatistical analysis (Fisher's Exact Binominal Test with Bondertoni Correction, one-sided greater, $\alpha = 0.05$) revealed no significant difference between control and any treatment group up to and including 316 mg test item/kg dry weight artificial soil. Therefore the No-Observed-Effect-Concentration (NOEC) for mortality is 316 mg test item/kg dry weight artificial soil. The Lowest-Observed-Effect-Concentration (LOEC) for mortality is 562 mg test item/kg dry weight artificial soil.

The LC₁₀ and CC₂₀ values for mortality were calculated to be 230 mg test item/kg soil dry weight (95% confidence limits: $\sqrt{31}$ - $\sqrt{30}$) and 277 $\sqrt{6}$ g test item/kg soil dry weight (95% confidence limits: 184 - 336), respectively.

Reproduction

Concerning the number of juveniles statistical analysis (Bonferroni-Welsh-t-test, one-sided smaller, $\alpha = 0.05$) evealed no significant difference between control and any treatment group up to and including 100 mg test item/kg dry weight artificial soil.

^{(*) =} Fisher's Exact Briomial Ost with Bonferroni Correction, one-sided greater = 0.05 = significant, -= not significant)

^{(**) = (}Bonferropi Welsh Fest; t-test, one oded smaller, α \$0.05, \$\to\$ significant, -= not significant)

¹⁾ Mortality = Weibull analysis; *eproduction = Probit analysis

^{2) =} Evaluation with 3 replicates

Therefore the No-Observed-Effect-Concentration (NOEC) for reproduction is 100 mg test item/kg dry weight artificial soil. The Lowest-Observed-Effect-Concentration (LOEC) for reproduction is 178 mg test item/kg dry weight artificial soil.

The EC₁₀ and EC₂₀ values for reproduction were calculated to be 98 mg test item/kg soil dry wight (95% confidence limits: 66 - 122) and 127 mg test item/kg soil dry weight (95% confidence limits: 95% - 151), respectively. - 151), respectively.

The most recent non-CLP-test (LAS-Coll-Ref-2876, Maria Ivonne , November 16, 2016) with the reference item Boric acid was performed at test concentrations 44, 67, 100, 150, 225 mg Boric acid/kg dry weight artificial soil Boric acid showed an EC₅₀ of 82 mg test item/kg dry weight aroticial soil (95% confidence limits from 57 mg to 112 mg Boric acid/kg dry weight artificial soil) for reproduction according Probit analysis using linear maximum likelihood regression. The result is in the recommended range of the guideline (about 100 mg Boric acid/kg artificial soil dry weight).

The NOEC reproduction was calculated to be 44 mg Boric acid/kg dry weight artificial soil and accordingly the LOFO reproduction is 44 mg Boric acid/kg dry weight artificial soil according Welsh-t-test after Bonferroni-Holm, = 0.05, one-sided smaller. This shows that test organisms are sufficiently sensitive.

^{2) %} WHC_{max} = percent of maximum water volding capacity of 48.7 fog water per 100 g dry weight artificial soil

Conclusions:

as to assess the effect of BCS-CN88460 5C 50 C/(Isin the soil mite species Hypoaspis aculeifer
imparing control and treatment. The purpose of this study was to assess the effect of BCS-CN88460 C 50 (Isothicypram EC 50) on mortality and reproduction of the soil mite species Hypogspis acuteifer tested during an exposure of 14 days in artificial soft by copring control and treatment.

Material and methods:

BCS-CN88460 EC 50 G, batch IDO 2016 001002, sample description: TOX20246-00; specification no.: 102000031262, sample ID: M16000677001; (analytical findings: 5.18% w/w (BCS-CN88460) equivalent to 50.46 g/L; density 0.974 mL (20 °C)).

Ten adult, fertilized female Hopoaspis aculeifer per replicate (8@eplicates for the control group and 4 replicates for each treatment group were exposed to control and treatments. Concentrations of 18, 32, 56, 100, 178, 316, 362 and 1000 mg test item/kg dry weight artificial soil were mixed into the artificial soil. During the test, the Hyppaspis occuleiter were fed with nematodes bred on watered oat flakes. During the study a temperature of 20 ± 2. © and Plight regime of 400 – 800 Lux, 16 h light: 8 h dark were applied. The artificial solv was prepared according to the guideline with the following constituents (percentage distribution of dry weight basis): 75% fine quartz sand, 5% Sphagnum peat, air driedand finely ground, 20% Kaolin class.

After a period of 14 days the surviving adults and the living juveniles were extracted by applying a temperature gradient using a Mad adventage apparatus. Extracted mites were collected in a fixing solution (20% ethylene glycol, 80% deionised water; 2 g detergent/L fixing solution were added). All Hypoaspis accideifer were counted wider a binocular.

Findings:

Calculations were done with un-rounded values.

Observations:

In the control groups 8% of the adult H poaspis aculeifer died which is below the allowed maximum

of \leq 20% mortality. Concerning the mortality of the adulfiest organisms statistical analysis (Fisher's Exact Binomial Test with Bonferron Correction one-sized greater, w = 0.05) revealed no significant difference between control and any treatment group of and picluding 1000 mg test item/kg dry weight artificial soil.

Therefore No-Observed-Effect-Concentration (NOEC) for mortality is ≥1000 mg test item/kg dry weight artificial soil. The Lowest-Observed-Effect-Concentration (LOEC) for mortality is >1000 mg test item/kg dry weight artificial

Concerning the number of giveniles statistical analysis (William's t-test, one-sided smaller, $\alpha = 0.05$) revealed no significant difference between control and any treatment group up and including 316 mg test item/kg dry weight artificial soil.

Therefore the No-Observed Affect-Concentration (NOEC) for reproduction is 316 mg test item/kg dry weight artificial soil. The Lowest-Observed-Effect-Concentration (LOEC) for reproduction is 562 mg test item/kg/dry weight artificial soil.

The EC O and EC 20 values for reproduction were calculated to be 362 mg (95% confidence limits: 349-375) and 422 mg (95% confidence limits: 410-432) test item/kg soil dry weight, respectively.

Calculations were done with un-roughted values.

Risk assessment for Soil Nitrogen Transformation

Risk Assessment for the product roflucy pram &C 50 for soil pricro-organisms **Table 8.5 - 2:**

Compound	Species PECsoil.max [mg.prod.kg] mg.prod./kg]	Refinement required
Isoflucypram 10 50	Soil micro-organisms 974 990	No

Rist Assessment for Isoflucyprain and its megabolite BCS-CN88460-carboxylic acid for soil micro-organisms

Compound Species Endpoint mg/kg	PEC _{soil,max} [mg/kg]	Refinement required
Isoflucypram	0.030	No
BCS-CN88460- carboxylic acid (M12) Soil micro-organisms 0.54	0.002	No

According to regulatory requirements the rock is acceptable, if the effect on nitrogen transformation at the maximum PEC_{50} values is <25% after 100 days. In no case, deviations from the control exceeded 25% after 28 days indicating low risk to soil micro-organisms.

Report: KCP 10.5/01; ; 2017; M-574633-02-1

Title: Amendment no. 1 to the final report - BCS-CN88460 EC 50 G: Effects on the activity

of soil microflora (Nitrogen transformation test) - Final report

Report No.: 16 10 48 062 N Document No.: M-574633-02-1

Guideline(s): EU Directive 91/414/EEC

Regulation (EC) No. 1107/2009 (2009)

US EPA OCSPP Not Applicable

Guideline deviation(s): none GLP/GEP: yes

Objective:

The aim of this study was to determine the effects of the test item on the activity of soil microflora with regard to nitrogen transformation in a laboratory test. The test was performed in accordance with OECD guideline 216 (2000) by measuring the utrogen turnover.

Material and methods:

Test item: BCS-CN88460 EC 50 G, Supplier Catch No.: 2016-001002, Sample description: TOX20246-00, Specification No.: 162000031262, analytical findings; 5.18% w/w (30.46 g/L) BCS-CN88460, Density (20 °C): 0.974 g/mL, water solubility: dispersible

A loamy sand soil (DIN 4220) was exposed for 28 days to 0.1 mg acs/kg soil dry weight, 0.5 mg a.s./kg soil dry weight and a control. Each treatment consisted of 3 replicates. Application rates were equivalent to 75 g a.s./ha (7.5 L product/ha) and 375 g a.s./ha (7.5 L product/ha) corresponding to test concentrations of 0.1 mg a.s./kg soil dry weight (9.5 mg prod/kg soil) and 0.5 mg a.s/kg soil dry weight (9.74 mg prod/kg soil). The nitrogen transformation was determined in soil enriched with lucerne meal (concentration in soil 0.5%). NH4-nitrogen, NO2 and NO2-nitrogen were determined by an autoanalyzer acdifferent sampling intervals (0, 7, 74 and 28 days after reatment). A reference item is not required by the guideline. Nevertheless Dinoterb is tested routinely as reference item in a separate study to verify the sensitivity of the test system.

Findings:

Experimental conditions:

The test conditions were 19.7 21.0 °C in a alfmatic and dark room, 43.29 to 45.24% of WHC_{max} and pH values of 6.2 to 6.3 in the soil. The water content of the soil in each test vessel was determined at test start (after application) and adjusted once a week to the required range of 40-50% of WHC_{max}. The pH values in the soil used in the test were measured at test start (after application) and at the final sampling on day 28.

A statisfical evaluation of the test results was performed by means of a 2-sided Student-t-test (for homogeneous variations at 5% significance level).

The test item BCS-CN88460 CC 50 G (Isoflucypram EC 50) caused temporary stimulation of the daily nitrate rate at the tested concentration of 0.1 mg a.s./kg soil dry weight at time interval 7-14 days after application.

No adverse effects of BCS-CN88460 EC 50 G on nitrogen transformation in soil could be observed at both to seed concentrations at the end of the test, 28 days after application (time interval 14-28). Differences from the control of + 6.3% (test concentration 0.1 mg test item/kg soil d.w.) and -9.7% (test concentration 0.5 mg a.s./kg soil d.w.) were measured at the end of the 28-day incubation period (time interval 14-28).

Time	Cont	rol		0.1 mg a.s./kg soil dry weight equivalent to 75 g a.s./ha				0.5 mg a.s./kg soil dry weight equivalent to 375 g a.s./ha

(75 L prod/ha). end of the 28-day incubation period. The study was performed in a field son at concentrations up to

CP 10.6 Effects on terrestrial non-target higher plants

For the product Isoflucypram EC 50 a dose response study on Terrestrial Plant Vegetative Vigour and a single dose study as well as a dose response study on Terrestrial Plant Seedling Emergence conducted to determine possible effects on seedling emergence and plant growth. The vegetative vigour and seedling emergence tests were carried out according to the OECD 227 and OECD 208 guidelines for the testing of chemicals, respectively.

Table 10.6-1: Effect values relevant for the risk assessment for non-target terrestrial plants for the product Isoflucypram EC 50

Test organism	Study type	Max. effects	Most sensitive species	Roferences 5
Maximum applic	cation rate: 75 g a.s./ha	(equivalent to 1.5 L pro	duct/ha) 👌 🧳	
Terrestrial non- target plants; 10 species	Vegetative vigour; Tier 2 dose response 21 days	No effects ≥ 50% at a rate of 75 gas.s./hax	(Zeti mays)	2917; M≈\$89028 091-1
Maximum applic	cation rate: 75 g a.s./ha	(eqûivalent to 1.5 Ø pro	duct/ha)	o' &' á
Terrestrial non- target plants; 10 species	Seedling emergence; Tier 1 single dose 21 days	No effects ≥50 % at (a rate of 75 a.s./ha)	Onion S	; 2017; \$59629\$- 01-1
Terrestrial non- target plants; 4 species	Seedling emergence; Tier 2 dose response 21 days	No effects \geq 50% at a rate of 75 ga.s./ha	Soy bean (Glycine mox)	, P,≼2017; №60726¥-01-1 КСР Ю.6.2/03

In the case of Isoflucypram EC 00, the Tier 2 vegetative vigour study and the Tier 1 and Tier 2 seedling emergence study showed no phytotoxic effects 50 % at the tested rate of 75 g a.s./ha (equivalent to 1.5 L product/hg).

Risk assessment for Terrestrial Non-Target Higher Plants

The risk assessment is based on the Guidance Document on Terrestrial Ecotoxicology", (SANCO/10329/2002 rev. 2 final, 2002). It is restricted to off field situations, as non-target plants are defined as non-crop plants located outside the treated frea. Effects on non-target plants are of concern in the off field environment, where non-target plants may be exposed to spray drift.

As it is clearly indicated that the maximum single application rate of 75 g a.s./ha (corresponding to 1.5 L product/ha) does not results in effects > 50%, according to the "Guidance Document on Terrestrial Ecotoxicology" (SANCO/10329/2002 rev 2 final 2002), no risk for non-target terrestrial plants is expected. Thus, no further risk assessment is required and no risk mitigation measures are regarded necessary.

Conclusion:

From the data presented above, it is concluded that unacceptable effects of Isoflucypram EC 50 on non-target terrestrial plants are not to be expected when the product is used as recommended.

CP 10.60 Summary of screening data

Not necessary as guideline OLP studies for terrestrial non-target plants are available (see Point 10.6.2 in this MCP summary).

CP 10.6.2 Testing on non-target plants

Report:

BCS-CN88460 EC 50 g/L - Effects on the vegetative vigor of ten species of non-target terrestrial plants (Tier 2) Title:

Report No.: VV17/001 Document No.: M-589028-01-1

Guideline(s): EU Directive 91/414/EEC

Regulation (EC) No. 1107/2009 US EPA OCSPP 850.4150 OECD 227 Vegetative vigor

Guideline deviation(s): none **GLP/GEP:** yes

Objective:

o Fo 50 Ple ence appli The objective of this specific study was to evaluate the effect of BCSC vegetative vigour of ten non-target terrace to the control of the con vegetative vigour of ten non-target terrestrial plant species following a post-mergence application of the test item onto the foliage of plants at the 2-4 leaf stage.

Material and methods:

Test item: BCS-CN88460 EC 60 g/L sample description: OX 50246-01, 5.28 % w/w (51.45 g/L). Supplier batch no: 2016-001002, specification no.: 102000031262. Appearance: Brown light turbid liquid. A total of 10 species, 6 divotyle fonous and 4 monocotyledorious species overe tested in this vegetative vigour test representing 8 plant families. The plants were grown in a greenhouse in 15 cm pots (filled with approx, 1.2 Levoil) The used soil was a lilt loam. Planting density included 2 or 4 plants per pot with 160 or 8 replicate pots, respectively, for a total of 32 plants per treatment level.

The plants were treated at the 24 leaf stage with 5 test item rates and a water control. The stock and application solutions were prepared in the laboratory and transported to the application site immediately before application. Second distributions of BCSCN88460 EC 50 g/L were sprayed onto the foliage of plants using a calibrated laboratory track sprayer at a volume rate of 200 L/ha. Details of the range of test item rates per species are summarized in the following lable:

X: Plant species tested with test item rate.

Control pots were sprayed with 200 L/ha of deionized water. After application, the plants were transferred back to the greenhouse and placed on the tables in a randomized design.

Following application, the pots with plants were maintained under greenhouse conditions, natural daylight was supplemented by artificial lighting. The temperature was regulated to maintain 19°C to 31°C during the light cycle (16 h) and 14°C to 26°C during the dark cycle (8 h). The relative humidity

was regulated to maintain 55-85 %. Assessments were made 7, 14 and 21 days after application. On day 7 and 14, only plant survival and visual phytotoxicity were recorded. Final assessments were made for plant survival, visual phytotoxicity, plant growth stage, shoot length and shoot dry weight, Statistical analyses of the data were performed to obtain NOER (No Observed Effect Rate), LOER (Lowest Observed Effect Rate), ER₂₅/ER₅₀ (Effect Rate producing 25 %/50 % effect) for survival, IR₂₅/IR₅₀ (Inhibition Rate producing 25 %/ 50% effect) for shoot length and Foot dry weight, using ToxRat statistical software.

Findings:

The germination rate of the seeds used in this study was $\geq 70\%$.

All plant species in this study met the validity criterion for survival in the controls (at least 90%). In accordance with US EPA guideline (OCSPP 850.4150) and OECD guideline (DECD 227), there was no visible phytotoxicity, and normal growth occurred in the controls of the ten species rested. The control plants of each species showed normal variation in growth, plant development and morphology. The environmental conditions during the test time were kept identical within each species. The pots used for all species of this study were filled in equal manker with the same soil.

The analysis of BCS-CN88460 content in the initial test mem stock solution revealed measured concentrations of 114 % of nominal.

The symptoms observed at the final assessment on day 21 after application in regetative vigour testing include chlorosis, necrosis deformation and stunting of the mants. In this study, the severity and occurrence of phytotoxic symptoms differed among species and test item rates and was slight.

The NOER, LOER, ER25/ER30 for survival, 1R25/1R350 values for shoot length and shoot dry weight expressed in g a.s./ha are summarized for each of the plant species in the following tables for the final assessment (on day 21 after application)

Codes for phytotoxic symptoms:

- a: chlorosis (yellowing of green shoot tissue)
- b: necrosis (e.g. brown shoot tissue, parts of the plant die)
- d: deformation (e.g. leaf curl, abnormal leaf shape, apprormal plant behitus)

d: deformation (e.g. leaf curl, abnormal leaf shape, abnormal plant habitus)
e: stunting (e.g. plant height reduced with shorter internods length, plant growth reduction)

Conclusion:

This vegetative vigour and growth study in which the effect of BCS-CN88460 FC 50 g/L on ten non-target terrestrial plant species also tasked under growth source and the respective requirements. target terrestrial plant species was tested under greenhouse conditions, resulted in no adverse effects on survival, visual phytotoxicity, growth stage development, shoot length and shoot dry weight above the 50% effect level.

For survival of all species no effects were observed up to the highest test item cate tested, there was 100 % survival of all species for all rates. Therefore the LOER was outside the range tested (>75 g a.s./ha) and the NOER reported a the highest rave tested (75 @ a.s./ha) and the ER25 and ER50 values could not be calculated and are reported as >750g a.s. that for all species.

For shoot length the IR and IR on values could not be calculated and are reported as >75 g a.s./ha for all species tested. The LOER was outside the range tested (>7\$ g a.s./ha) and the NOER reported as the highest rate tested (75 g/a.s./ba) except for Zea mays, the LOER was calculated to be 75 g a.s. ha and the NOER 32.5 g a.s. ha.

For shoot dry weight the R25 and IR500 values could not be calculated and are reported as >75 g a.s./ha for all species tested. The OER was outside the range tested (>75 g a.s./ha) and the NOER reported as the highest are tested (75 g a.s Dna) for the following species Cucumis sativus, Allium cepa, Avena sativa and Lolium perenne. For Bara vulgaris, Brassica napus, Glycine max, Helianthus anguus and Solonum Weoperstrum, the LOBR was calculated to be 75 g a.s./ha and the NOER 37.5 g a.s./ha. For Zea mays, the LOER was calculated to be 18.8 g a.s./ha and the NOER 9.4 g a.s./ha. The most sensitive species for this parameter was Helianthus anuus, showing 16.0 % inhibition at the test rate of 75 g a.s./ha. NOER 37.5 g a.s./ha. For Zea mays, the LOPR was calculated to be 18.8 g a.s./ha and the NOER

The objective of this specific study was to evaluate the potential effect of BCS the control of BCS the objective of this specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the potential of the specific study was to evaluate the specific study was the specific study was to evaluate the specific study w on the seedling emergence and growth of ten species of non-target terrestrial plan emergence application of the product to the soil surface.

Material and methods:

Test item: BCS-CN88460 EC 50 g/L, sample rescription: TOX 20246-01 Supplier batch no: 2016-001002, specification no: 102000031262. Appearance: Brown light turbid liquid. A total of 10 species, 6 dicoryledonous and 4 monocoryledonous species were tested in this seedling emergence test representing 8 plant families. The seeds were sown on the day of the application of the test item to the soil surface in 15 cm pots Willed with prox 3.2 L soil). The used soil was a silt loam.

Planting density included 2 or 4 seeds perport, with 20 or 10 replicate pot replicate pots, respectively, for a total of 40 seeds (20 seeds) per treatment level.

The test was conducted as a limit test, the sown seeds of the plant species were treated with a single test item application rate and a water control.

The stock and application solutions were prepared in the laboratory and transported to the application site immediately before application.

The single rate 19 g as ha of BCS-CN88460 EC 50 g/L was applied once at test initiation to the soil surface using a calibrated laborator track sprayer at a volume rate of 200 L/ha.

X: Plant species tested with test item rate.

Control Pots were sprayed with 200 L/ha of deionized water.

After application, the pots with seeds were transferred back to the greenhouse and placed on the tables in a randomized design. During the course of the experimental study part the pots of each plant species were reachinged within each species plot.

Following application, the pots with plants were maintained under greenhouse conditions, natural daylight was supplemented by artificial lighting The temperature was regulated to maintain 19°C to

31°C during the light cycle (16 h) and 14°C to 26°C during the dark cycle (8 h). The relative humidity was regulated to maintain 55 to 85%.

The control pots of each species were observed daily for the number of seedlings emerged until 50% of the seedlings had emerged (= day 0). Assessments were made individually for each species of this day (= day 0) and 7, 14 and 21 days post emergence of 50 % of the control seedlings. On day 67 and 14, only plant emergence, survival and visual phytotoxicity were recorded.

Final assessments (21 days post emergence of 50 % of the control seedlings) were made for emergence, plant survival, visual phytotoxicity, plant growth stage, shoot length and shoot dry weight. Statistical analysis of emergence, survival, shoot length and shoot dry weight data was carried out with the Mann-Whitney-U-Test (one sided smaller; $p \le 0.05$) included in Too Rat statistics.

Findings:

The germination rate of the seeds used in this study was ≥ 70 %

All species in this study met the validity criteria for spedling emergence (at least 70 %) and survival (at least 90 %) in the controls. In accordance with OECD guideline (OCSPP 850.4100), there was no visible phytoxicity, and normal growth occurred in the controls of the ten species tested. The control plants of each species showed normal variation in growth, plant development and morphology. The environmental conditions during the test time were kept identical within each species. The pots used for all species of this study were filled in equal manner with the same soil.

The analysis of BCS-CN88460 content in the initial test tiem stock solution revealed measured concentrations of 113 % of normal.

As a result of this seedling emergence and growth study, in which BCS-CN88460 EC 50 g/L was tested on 10 species of non-target perrestrial plants with the test item rate of 75 g a g./ha, minor effects on the growth stage of Beta vulgaris, Helanthus annuls and Zea mays were seen at the final assessment. For all other plant species tested no adverse effects on the growth stage development were found in comparison to the control. Meassich napits, Cucumis Sativus, Glycine max, Solanum lycopersicum, Allian cepas Avena sativa and Lolium berenne exhibited normal variation in the growth stage development compared to the control.

At the final assessment, no phytotoxic symptoms were observed for Beta vulgaris, Glycine max, Helianthus annuus, Solanum lycopersicum, Allium cega, Avena sativa, Lolium perenne and Zea mays at the test tem rate of \$15 g ass/ha. Sight phytotoxic symptoms were observed in a few cases for Brassica napus (1.5% stuntion) and Cucumis sativas (1.0%, chorosis, necrosis).

At the test item rate of 75 g a.s./ha emergence for Lotium perenne was reduced by 11.1 %, compared to the water treated controls. This reduction was no ostatistically significant. There was no negative effect on emergence of the other species tested Beta sulgaris, Brassica napus, Cucumis sativus, Glycine max, Delianthus annuus, Sofanum Oycopersicum, Allium cepa, Avena sativa and Zea mays).

There was no negative effect on survival at the test icm rate of 75 g a.s./ha for any species tested at the final assessment.

Compared to the control plants. Shoot length was reduced by 4.0 % for Beta vulgaris and for Brassica napus by 6.2 % at the test tem rate of B g a.s. ha. This reduction was statistically significant. The reduction of shoot length for Greine max (15 %), Helianthus annuus (1.5 %), Allium cepa (7.4 %) and Zea mays (2.5 %) was not statistically significant. There was no reduction of shoot length observed for Cucumis sativus, Solarum lycopersicum, Avena sativa and Lolium perenne, compared to the control plants.

At the test item rue of by a sha compared to the control plants **shoot dry weight** for *Beta vulgaris*, *Glycine max*, and *Allium cena* was statistical significantly reduced by 7.3 %, 1.9 % and 19.4 %, respectively for *Helianthus annuus* and *Zea mays* shoot dry weight was not statistical significantly reduced by 3.0 % and 9.7 %, respectively. For all other plants tested (*Brassica napus*, *Cucumis sativus*, *Solanum lycopersicum*, *Avena sativa* and *Lolium perenne*) no reduction was observed compared to the control plants.

The following table summarises per cent inhibition of emergence, survival, shoot dry weight and shoot length as calculated for the final assessment (21 days after 50 % emergence of the control seedlings). In addition, ratings of phytotoxicity and growth stage (BBCH) are provided for all species tested.

	Ohsei	rvations at 1	the test item rate of	75 σ a s /l	19	ввсн

Title: Effects on the seedling emergence and growth of four species of non-target terrestrial

plants (Tier 2) Isoflucypram EC 50 g/L

Report No.: SE17/056
Document No.: M-607264-01-1

Guideline(s): US EPA OCSPP 850.4100 (2012)

OECD 208 (2006)

Guideline deviation(s): none GLP/GEP: yes

Objective:

The objective of this specific study was to evaluate the potential effect of BCS-CN88460 EC 50 gA on the seedling emergence and growth of four species of non-target terrestrial plants following a pre-emergence application of the product to the soft surface.

Material and methods:

Test item: BCS-CN88460 EC 50 g/L sample description, TOX 20246-01, 5.28% www (51.45 g/L). Supplier batch no: 2016-001002, specification inc. 102000031/62. Appearance: Brown light turbid liquid. Four crop species, 3 dicovyledonous and 1 monocotyledonous species were rested in this seedling emergence test representing 4 different plant species. The seeds were sown on the day of application of the test item to the soil surface in 15 cm pots (filled with approximately 1.2 L soil). The used soil was a silt loam.

Planting density included or 4 seeds per pot with 20 or 10 replicate pots respectively, for a total of 40 seeds per treatment level (test item rates, water control)

The sown seeds of each of the plant species, were created with 5 lest item rates or a water control.

The stock and application solutions were prepared in the laboratory and transported to the application site immediately before application.

Serial dilution of isoflucypram EC 50 of L were sprayed to the sofl surface using a calibrated laboratory track sprayer at a volume rate of 200 tha. Details of the range of test item rates per species are summarized in the following table.

Species name	EPRO CODE	Common name		Test iten	ı rates in	g a.s./ha	
Species name	EAG O COOPE		4.7	9.4	18.8	37.5	75

X: Test item rate tested

Control pots were sprayed with 200 L/ha of defonized water.

After application, the pots with seeds were transferred back to the greenhouse and placed on the tables in a randomized design with all poss of one species arranged together in a species plot. During the course of the experimental study part, the pots of each plant species were rearranged within each species plot.

Following application, the poss with plants were maintained under greenhouse conditions and natural daylight was supplemented by artificial lighting The temperature was regulated to maintain 19°C to 31°C during the light cycle (16 h) and 14°C to 26°C during the dark cycle (8 h). The relative humidity was regulated to maintain 55 to 85% during dark and light cycle.

The control pots of each species were observed daily for the number of seedlings emerged until 50% of the seedlings had emerged (= day 0). Assessments were made individually for each species on this

day (= day 0) and 7, 14 and 21 days post emergence of 50% of the control seedlings. On day 0, 7 and 14, only plant emergence, survival and visual phytotoxicity were recorded.

Final assessments were made for emergence, plant survival, visual phytotoxicity, plant growth stage, shoot length and shoot dry weight 21 days post emergence of 50% of the control seedlings.

Statistical analysis of the data were performed to obtain NOER (No Observed Effect Rate) OER (Lowest Observed Effect Rate), ER₂₅/ER₅₀ (Effect Rate) for emergence, surviver, IR₂₅/IR₅₀ (Philbition Rate) for shoot length and shoot dry weight, using ToxRat statistical software

Findings:

The germination rate of the seeds used in this study was $\frac{8}{2}$ 70%.

All species in this study met the validity criteria for seedling emergence (at least 70%) and survival (at least 90%) in the controls. In accordance with OECD guideline (QECD 208) and US EPA guideline (OCSPP 850.4100), there was no visible phytotox wity, and normal growth occurred in the controls of the four species tested. The control plants of each species showed normal variation in growth plant development and morphology. The environmental conditions during the jest time were kept identical within each species. The pots used for all species of this study were filted in equal pranner with the

The analysis of isoflucypram (BCS-CN 88469) content in the initial test item stock solution revealed measured concentrations of 108% of rominals

Symptoms observed at the final assessment (day 2) after 50% control seedling emergence), in seedling emergence testing include chlorosis, necrosis, deformation and stunting of the seedings. In this study, the severity and occurrence of phytotoxic symptoms differed among species and test item rates and was mainly slight and sporadically.

The NOER, LOER, ER₂₅/ER₅₀ for smergence and survival, IR₂₅/IR₅₀ values for shoot length and shoot dry weight expressed in s.a.s./ha are summarized for each of the plant species in the following tables for the final assessment (21 days after 50% emergence of the control seedlings)

- Codes for phytotox symptoms:
 a: chlorosis (yellowing of green boot tissue)
 b: necrosis (e.g. brown shoot tissue, parts of the Flant die)
 c: bleaching e.g. shoot tissue without pigmentation)
 d: deformation (e.g. leaf curl, abnomal leaf shape, abnormal plant habitus)
 e: stuning (e.g. plant height reduced with shorter internode length, plant growth reduction)
 f: reddening orddening of green shoot tissue)
 Any plant considered as being dead was not rated for phytotoxicity.

n.d.: Confidence limits not determined (outside the range tested)

n.d.: Confidence limits not determined (outside the range tested)

a: Not calculated (outside the range tested).

Conclusion:

This seedling emergence and growth study, in which the effect of Isoflucypram EC 50 g/L on four non-target terrestrial plant species was tested under greenhouse conditions, resulted in no adderse effects on emergence, survival, shoot length, shoot dry weight, growth stage development of sisual phytotoxicity above the 50% effect level.

No statistically significant differences were found for emergence, survival, shoot length or shoot dry weight between treated plants and plants in the control of any species tested. For all measurements and species, the LOER was outside the range tested and the NOER reported as the highest test item ate of 75 g a.s./ha. The ER₂₅/IR₂₅ and ER₅₀/IR₅₀ values for all species tested were higher than the kighest test item rate and could not be calculated and are therefore reported as > 75 g a.s./ha.

CP 10.6.3 Extended laboratory studies on non-target plants

In view of the results presented under Point Ck 10.6.2 above no further studies are deemed necessary.

CP 10.6.4 Semi-field and field tests on non-target

In view of the results presented under Point CP

Effects on other terrestrial organisms (flora and fruna) **CP 10.7**

No further tests on other terrestrial organism deemed to be decessary due to the low to moderate acute and chronic ecotoxicity of Isoflucypram EC 50 to presented under the Points CP 10.1 to CP 10.6 in this MCP Summary

CP 10.8 ©

the application of the comme and the comme and the comme are the comme and the comme are the comme and the comme are the comme a No mornioring data has been collected by the applicant nor have they been reported in any of the public literature references as evaluated of Document MCA. Section 9. Due to the low to moderate acute and chronic ecotoxicity of Isoffreypram ECO as presented under the Points CP 10.1 to CP 10.7, no monitoring of non-target organism is deemed to be necessary.
