Autophagic flux - In the control and in the cells treated with glyphosate at 100 µg/mL, mCherry-GFP-LC3B is present in the form of diffuse yellow fluorescence which is indicative of the absence of autophagy.

Colocalization of mitochondria and lysosomes - The relative coefficient of colocalization between Mito and Lyso was 0.22 ± 0.01 for the control and 0.21 ± 0.02 for the cells treated with glyphosate at 100 µg/mL.

Opening of the mitochondrial permeability transition pore (mPTP) - When compared with the $CoCl_2$-treated control group, no significant increase in fluorescence was noted in the cells treated with glyphosate at 100 µg/mL which is indicative of the absence of mPTP opening.

Immunoblotting of proteins linked with autophagy - The effect of glyphosate on the autophagy related proteins beclin-1, LC3-II/I, and p62 was studied by immunoblotting. When compared with the control no difference was found in the expression ratio of LC3-II/I as well as protein expression of beclin-1 in cells treated with glyphosate at 100 µg/mL. Immunoblotting was also used to examine the phosphorylation of mTOR, AMPK, and p70s6k. No difference in phosphorylation levels of mTOR, p70s6k, and AMPK could be demonstrated in cells treated with glyphosate at 100 µg/mL when compared to controls. These results indicate that glyphosate does not contribute to the activation of the AMPK/mTOR pathway.

Adenosine triphosphate (ATP) content - When compared with the control, no difference was found in the levels of cellular ATP of cells treated with glyphosate at 100 µg/mL.

Conclusion

All commercial glyphosate formulations are more toxic than glyphosate so that the increased toxicity may be attributed to the adjuvants. The herbicidal active substance of Roundup is glyphosate isopropylamine salt and its main adjuvant is polyethoxylated tallow amine (POEA). To explore whether the herbicidal active substance or the adjuvant contributes Roundup's ability of inducing autophagy in human A549 cells, TEM, MDC, immunoblotting, and Ad-mCherry-GFP-LC3B analyses were performed on 4 concentrations of Roundup from 50 to 125 µg glyphosate acid eq./mL and one concentration of glyphosate (100 µg/mL) and POEA (35 µg/mL). This study revealed that the commercial formulation Roundup has the ability to cause autophagy in A549 cells *via* the AMPK/mTOR signaling pathway. Previous studies showed that compared with glyphosate, commercial glyphosate based herbicides are more toxic, and the toxic effect is highly correlated with the adjuvant POEA. This study indicates that the adjuvant POEA in Roundup contributes to its ability of inducing autophagy in A549 cells, and that the herbicidal active substance glyphosate has no contribution.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The effect of glyphosate, POEA and a herbicidal formulation containing POEA as a co-formulant on the AMPK/mTOR signaling pathway was studied in human alveolar carcinoma A549 cells *in vitro*. Only the results of exposure to glyphosate at 100 µg/mL are reported and discussed in this summary. The endpoints selected to study the effect of glyphosate on autophagy are inhibition of viability, monodansylcadaverine (MDC) staining to mark autophagic vacuoles, visualization of double-membrane

autophagosomes by TEM, autophagic flux, colocalization of mitochondria and lysosomes, opening of the mitochondrial permeability transition pore (mPTP), expression of proteins involved in the AMPK/mTOR signaling pathway, and ATP content. No effect could be demonstrated of glyphosate on any of these endpoints indicating that glyphosate, in contrast to POEA and Roundup, does not contribute to the activation of the AMPK/mTOR signaling pathway and has thus no role in autophagy.

This publication is relevant for the risk assessment of glyphosate but reliable with restrictions because only one glyphosate concentration was tested and no positive controls were used.

2. Full summary of the study according to OECD format

In this paper a pooled reanalysis of the data from 2 published non-Hodgkin's lymphoma (NHL) case control studies was conducted: McDuffie *et al*. 2001 and DeRoos *et al*. 2003. The reanalysis sought to evaluate associations for glyphosate use and NHL overall and by histological sub-type. In addition, the pooled analysis implemented more extensive control of confounding factors than in the original publications and considered the impact of excluding pesticide information provided by next-of-kin or proxy respondents. The OR for NHL overall for ever using glyphosate was 1.4 (95 % CI 1.1, 1.8). After adjustment for other pesticides, the OR was reduced to 1.1 (95 % CI 0.8, 1.5). ORs for ever using glyphosate, adjusted for other pesticides, by NHL sub-type were 0.7 (95 % CI 0.4, 1.2) for FL, 1.2 (95 % CI 0.8, 1.9) for DLBCL, 1.8 (0.9, 3.7) for SLL, and 1.5 (95 % CI 0.9, 2.6) for other NHL sub-types. Adjusted ORs excluding data from proxy respondents [supplemental table 1 in the article] were: 0.95 (95 % CI 0.7, 1.3) for NHL overall, 0.7 (95 % CI 0.4, 1.1) for FL, 1.1 (95 % CI 0.7, 1.8) for DLBCL, 1.8 (0.0, 3.8) for SLL, and 0.96 (95 % CI 0.5, 1.9) for other NHL sub-types. ORs for NHL overall were not elevated in the higher categories for years of use (> 3.5 years OR 0.9, 95 % CI 0.6, 1.4) or lifetime days of use (> 7 days OR 1.1, 95 % CI 0.7, 1.8) though there was an elevated OR for the category of more than 2 days of use/year (OR 1.7, 95 % CI 1.0, 2.9). For NHL subtypes, consistent patterns of association across exposure metrics were not seen, with the possible exception of SLL, though SLL findings were not statistically significant. In general, exclusion of proxy respondents reduced ORs to a minor extent with the exception of the analyses for other NHL subtypes. For NHL overall, ever use and analyses that considered duration of use per se or lifetime days of use did not show a relationship with glyphosate. There was a moderate association seen for glyphosate use for the metric > 2 days/year. There was some limited evidence of an association between glyphosate use and SLL across exposure metrics, but the small number of SLL cases resulted in very imprecise OR estimates as evidenced by wide 95 % CIs. The major limitation of the study is possible case recall bias in the reporting of prior pesticide use.

Materials and methods

Study population and exposure assessment
Pahwa *et al*. pooled data from case control studies in the US and Canada. For NHL specifically, this study is essentially a reanalysis of the published studies by McDuffie *et al*. (2001) in Canada and DeRoos *et al*. (2003) in the US. Case identification in the US was through cancer registries and hospitals during the 1980s in four US states (Iowa/Minnesota, Kansas, and Nebraska) and between 1991 and 1994 in six Canadian provinces (Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia). Methods for each study have been previously described. For this pooled analysis, the original histology codes were revisited and classified according to a single scheme [International Classification of Diseases for Oncology version 1 (ICD-O-1)].

Participants, or their proxies, provided information about demographic characteristics, pesticide use, agricultural exposures, and exposure to other known or suspected NHL risk factors, including lifestyle and medical and occupational history. Self-reported glyphosate use was examined using several exposure metrics: ever/never, duration (years used), frequency (days/year handled), and lifetime-days (number of years used multiplied by number of days/year handled). Categories were created for duration, frequency, and lifetime-days analyses based on the median of glyphosate used/handled among controls. Some participants had missing data for duration and frequency of glyphosate use despite reporting that they had ever used glyphosate. In duration and frequency analyses, values for missing data were assigned to cases and controls based on the median duration or frequency of reported glyphosate use among controls by state/province and 10-year age group (simple imputation) and were used for the main analyses. Ordinal analyses and associated trend tests were conducted to determine possible changes in association for increasing increments of every five years, five days/year, and ten lifetime-days of glyphosate use.

Statistical analyses
Unconditional multiple logistic regression was performed using the LOGISTIC procedure of the SAS 9.4 statistical software package (SAS Institute, Cary, NC, USA) to calculate ORs and 95 % CIs for associations between glyphosate exposure metrics (ever/never, duration, frequency, lifetime-days, and as ordinal variables) and NHL overall and by histological sub-type [diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), small lymphocytic lymphoma (SLL), and other]. Initial logistic regression models (OR) contained the following variables: age [age at diagnosis (cases); age at interview or death (controls)], state/province, sex, lymphatic or hematopoietic cancer in a first-degree relative, response by a proxy, and use of any personal protective equipment (PPE). Pesticides that were correlated with glyphosate use in the pooled data and that had previously been associated with NHL based on the individual case-control studies, specifically 2,4-dichlorophenoxyacetic acid, dicamba and malathion, were included in the more fully adjusted logistic regression models (OR). The former models will be referred to as crude and the latter models as adjusted.

Trends for duration, frequency, and lifetime-days of glyphosate use and NHL ORs were assessed by the asymptotic Cochran-Armitage trend test. Subjects who never used glyphosate were the reference group for all analyses. There was a small proportion of subjects (N=175, 2.6 % of all participants) with missing age values. These were imputed using simple imputation based on state/province- and case/control-specific means of age rounded to the nearest whole number. Sensitivity analyses were conducted by excluding proxy respondents from the main analyses.

Ethics approval and consent to participate
Ethics approval for the pooled analysis was obtained from the University of Toronto Health Sciences Research Ethics Board (#25166) and an exemption was obtained from the US National Institutes of Health Office of Human Subjects Research (#11351). Investigators of individual studies received human subjects' approval from their institutions for each study prior to collection of data.

Results

Characteristics of NHL cases and controls

A total of 1690 NHL cases and 5131 controls was available for analysis – 69.6 % of the cases and 70.6 % of the controls were from the US studies. All NHL cases and controls, including those with proxy respondents, were included in analyses of ever/never glyphosate use. For assessments involving duration of use, 1520 cases and 4183 controls were included. For frequency and lifetime-days analyses, 898 cases and 2938 controls were included. The numbers of cases and controls available for the sensitivity analysis excluding proxy respondents were smaller (Figure 1). Characteristics of NHL cases and controls, including histological sub-types, are presented in Table 1.

Figure 5.5.2-5. Subjects in main and proxy respondent analyses of glyphosate use and NHL in the North American Pooled Project (NAPP). * Duration (years) information was not collected in Kansas, ** Frequency (days/year) information was not collected in Iowa, Minnesota, and Kansas.

Glyphosate use and associations with NHL overall and by major histological sub-type

Overall, 113/1690 cases (7 %) and 244/5131 (5 %) controls reported having used glyphosate at any point in their lifetime. In crude analyses, there was a significant association between ever use of glyphosate and NHL overall (OR1.4, 95 % CI 1.1–1.8) that was attenuated appreciably when adjusted for ever use of the pesticides 2,4-D, dicamba, and malathion (OR1.1, 95 % CI 0.8–1.5) (Table 2).[21] Adjusted ORs by for NHL subtypes were: 0.6 (95 % CI 0.4 – 1.2) for FL, 1.2 (95 % CI 0.8–1.9 for DLBCL, 1.8 (95 %CI 0.9 – 3.7) for SLL, and 1.5 (95 % CI 0.9 – 2.6) for other NHL subtypes.

When ORs for NHL and glyphosate use were examined by duration, there were lower ORs with longer use for NHL overall and for subtypes except SLL (see table 2). Conversely, there were higher ORs for those who reported use for more than 2 days per year verses those who reported use ≤ 2 days per year. Analyses by lifetime days of use – the metric used in most studies – showed near null results for all subtypes in the higher lifetime days category, except for SLL. It bears noting that the analyses by duration included 90 % of cases and controls (Kansas subjects did not have the required data), while the analyses of days/year and lifetime days included only 53 % of subjects (cases and controls from Kansas, Iowa, and Minnesota did not have the required data and were excluded). As such, these latter analyses may not be representative of results for the entire pooled study population.

[21] Adjusting for other pesticides appreciably changed the NHL OR for glyphosate. Therefore, it seems most appropriate to focus on the ORs from the adjusted analyses.

Table 5.5.2-62: Adjusted Odds Ratios (95 % confidence intervals) by Various Glyphosate Exposure Metrics

Metric	NHL overall	FL	DLBCL	SLL	Other NHL
ever use	1.1 (0.8, 1.5)	0.6 (0.4, 1.2)	1.2 (0.8, 1.9)	1.8 (0.9, 3.7)	1.5 (0.9, 2.6)
duration					
≤ 3.5 years	1.3 (0.9, 1.8)	0.7 (0.3, 1.3)	1.6 (0.97, 2.7)	1.4 (0.6, 3.7)	1.8 (0.95, 3.5)
> 3.5 years	0.9 (0.6, 1.4)	0.6 (0.3, 1.3)	0.9 (0.5, 1.7)	1.9 (0.8, 4.8)	1.1 (0.5, 2.5)
days/year					
≤ 2	0.7 (0.5, 1.2)	0.4 (0.2, 1.2)	0.7 (0.4, 1.4)	1.3 (0.4, 4.3)	1.1 (0.5. 2.7)
≥ 2	1.7 (1.0, 2.9)	1.3 (0.6, 3.2)	2.1 (1.1, 4.3)	2.3 (0.6, 8.8)	1.6 (0.6, 4.5)
lifetime days					
≤ 7	0.9 (0.5, 1.5)	0.6 (0.3, 1.6)	0.8 (0.4, 1.7)	1.0 (0.2, 4.8)	1.4 (0.6, 3.5)
> 7	1.1 (0.7, 1.8)	0.8 (0.3, 1.8)	1.1 (0.6, 2.2)	2.2 (0.7, 6.9)	1.3 (0.5, 3.3)

Sensitivity analyses excluding proxy respondents

A sensitivity analysis was performed by excluding cases and controls whose data were provided by proxy respondents. The overall pattern of OR estimates were generally similar to the main analyses. However, for SLL, ORs were slightly higher in the > 2 days/year subgroup OR 2.3 (95 % CI 0.6, 8.8) with proxies compared to OR 2.6 (95 % CI 0.7, 10.1)) without proxies. For other NHL subtypes, ORs were slightly to appreciably lower for ever use with proxies OR 1.5 (95 % CI 0.9, 2.6) compared to OR without proxies of 1.0 (95 % CI 0.5, 1.9); OR for > 3.5 years of use 1.1 (95 % CI 0.5, 2.5) compared to OR without proxies 0.5 (95 % CI 0.2, 1.6)); and OR for > 7 lifetime days with proxies 1.4 (95 % CI 0.6, 3.5) compared to OR without proxies of 1.1 (95 % CI 0.4, 3.3)).

Discussion & Conclusion

The objective of this study was to evaluate potential associations between glyphosate use and NHL in the NAPP, a pooled dataset that allowed for a more comprehensive analysis than previously possible in the individual studies. For NHL overall, the OR for ever use of glyphosate and NHL was near null when adjusted for reported use of 2,4-D, dicamba, and malathion (OR1.1, 95 % CI 0.8, 1.5). Analyses by years of use and lifetime days of use showed near null results for NHL overall (OR 0.9 and 1.1, respectively), while the OR for > 2 days/year was elevated (OR 1.7, 95 % CI 1.0, 2.9). It bears noting, however, that the analyses by days per year and lifetime days of use included only 50 % of the pooled population – essentially the Canadian subjects and 1 of the 4 US case-control studies. It is uncertain, therefore, how representative these results are for the entire pooled population. The results of those analyses should be interpreted accordingly.

In analyses of NHL sub-types, there tended to be moderate positive associations between the various glyphosate exposure metrics and SLL. However, as there were only 15 SLL cases overall who ever used glyphosate and 14, 7 and 7 exposed SLL cases in the analyses by years of use, days per year, and lifetime days of use, respectively, the results were not statistically significant and the 95 % CIs were imprecise. For other cell types, there were moderate positive relationships for glyphosate use of more than 2 days per year, though ORs were near null for these cell types for the higher category of years of use and lifetime days of use.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The main advantage of this pooled analysis compared with the previously published individual studies was to enable a more comprehensive analysis for glyphosate with regard to confounding factors and proxy respondents. In general, adjusting for use of 2,4-D, dicamba, and malathion reduced ORs for glyphosate. Analyses that excluded proxy respondents were generally similar to analyses that included

them, though there were some instances, specifically for other NHL subtypes, where excluding proxies appreciably reduced the adjusted OR.

Left unaddressed in this pooled analysis is the intractable issue of case-recall bias in case control studies. Crump has shown in an analysis of all the case control studies that have reported ORs for glyphosate, including the studies in this pooled analysis, that results for all pesticides were markedly skewed toward positive associations (Crump K, Risk Analysis DOI: 10.1111/risa.13440). Crump noted particularly that the ORs for individual pesticides in the McDuffie *et al*. study (and 2 other studies not included in this pooled analysis) were nearly all greater than 1.0. He considered this evidence of case recall bias. Fundamentally, using self-reported exposure recollections from cases and controls violates the basic principle that data should be collected under equivalent circumstances for the groups to be compared (viz., cases and controls). That is impossible when pesticide recall is likely to be affected by their grievous illness for cases and not for controls. Accordingly, while this pooled analysis is an advance in understanding confounding by other pesticides and in assessing the impact of reporting by proxies (except in analysis where 50 % of the subjects were excluded due to data limitations) in the 2 included studies, systematic error related to case recall bias remains an outstanding issue for interpreting the results for glyphosate.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because it concerns a pooled case control study which is subject to recall and selection bias. Notably, potential case-recall bias remains an unresolved issue in this pooled reanalysis.

Assessment and conclusion by RMS:

Reliability Criteria: Epidemiology studies

Publication: Pahwa M. *et al.,* 2019	**Criteria met? Y/N/?**	**Comments**
Study Design		
Adequate study design given study objectives	Yes	Pooled reanalysis of 2 previously published studies.
Appropriate study population to address potential glyphosate-related health outcomes	Uncertain	Populations had very limited glyphosate exposure frequency.
Exposure studied		
Exposure to formulations with glyphosate as a.s.	Yes	
Exposure to formulations with other a.s.	Yes	
Exposure to other farm exposures	Uncertain	
Study Conduct/analysis		
Adequate description of study population	Yes	
Adequate description of exposure circumstances	Yes	
Comparable participation by groups being compared	No	Much less participation by controls: example: McDuffie study –

Publication: Pahwa M. *et al.,* 2019	**Criteria met? Y/N/?**	**Comments**
		participation 67 % for cases, 48 % for controls.
Information provided by proxy respondents	Yes, substantial	31 % for cases, 40 % for controls in DeRoos study; 21 % for cases, 15 % for controls McDuffie study (per Chang & Delzell 2016)
Adequate statistical analysis	Yes	More comprehensive than the original publications regarding confounding & proxy responses. Data for 47 % of subjects were missing for analyses by days of use per year and lifetime cumulative days of use.
Adequate consideration of personal confounding factors	Yes	Better than original studies.
Adequate consideration of potentially confounding exposures	Yes	Better than original studies
Overall assessment		
Reliable without restrictions		
Reliable with restrictions	Yes	
Not reliable		
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because illustrates bias toward positive findings for glyphosate in the original publications due to confounding and, in part, due to proxy responses. Recall bias unresolved. Missing data for 47 % of subjects for analyses by days/year of use and lifetime cumulative days of use hinders interpretation of related results.

Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

Glyphosate is the most widely used herbicide in the USA and worldwide. There has been considerable debate about its carcinogenicity. Epidemiological studies suggest that multiple myeloma (MM) and non-odgkin lymphoma (NHL) have a positive and statistically significant association with glyphosate exposure. As a B cell genome mutator, activation-induced cytidine deaminase (AID) is a key pathogenic player in both MM and B cell NHL. Vk*MYC is a mouse line with sporadic MYC activation in germinal center B cells and considered as the best available MM animal model. Vk*MYC mice and wild-type mice were treated with drinking water containing 1000 mg/L of glyphosate and examined animals after 72 weeks. Vk*MYC mice under glyphosate exposure developed progressive hematological abnormalities and plasma cell neoplasms such as splenomegaly, anaemia, and high serum IgG. Moreover, glyphosate caused multiple organ dysfunction, including lytic bone lesions and renal damage in Vk*MYC mice. Glyphosate-treated wild-type mice developed benign monoclonal gammopathy with increased serum IgG, anaemia, and plasma cell presence in the spleen and bone marrow. Finally, glyphosate upregulated AID in the spleen and bone marrow of both wild-type and Vk*MYC mice. Conclusions: These data support glyphosate as an environmental risk factor for MM and potentially NHL and implicate a mechanism underlying the B cell-specificity of glyphosate-induced carcinogenesis observed epidemiologically.

Materials and methods

Mouse model and treatments; All chronic and acute animal experiments were performed in accordance with NIH guidelines and under protocols approved by the Cleveland Clinic Institutional Animal Care and Use Committee. Wild-type (WT) C57Bl/6 mice were purchased from the Jackson Laboratory (Bar Harbor, ME). Vk*MYC mice in the C57Bl/6 genetic background were obtained from Dr. Leif Bergsagel (Mayo Clinic, Scottsdale, AZ). Vk*MYC and WT mice were intercrossed to obtain WT and Vk*MYC littermates. Sex-matched WT and Vk*MYC mice (8 weeks old) were assigned to treatment or control groups based on body weight. For chronic study of glyphosate effects, treatment groups were provided 1.0 g/L glyphosate (Sigma-Aldrich, St. Louis, MO) in their drinking water for 72 weeks. Regular drinking water was provided for the control groups (Fig. 1a). Every 6 weeks, blood was collected from the tail vein of mice, and the serum IgG level was measured. At week 72, the remaining 3 surviving Vk*MYC mice reached humane endpoints. These 3 treated Vk*MYC mice were used for M-spike detection and pathologic analyses, along with mice from other groups. Other Vk*MYC mice that were sacrificed before week 72 were analysed for total serum IgG levels, complete blood cell count, and total serum creatinine. For comparison, mice from other groups were euthanized at week 72 and their tissues and blood analyzed. For acute treatment, 8-week old mice (n = 5 per group) were given 0, 1.0, 5.0, 10.0, or 30.0 g/L of glyphosate for 7 days before sacrifice. The same variables were analyzed in the acute study.

Blood and post-mortem assays; Whole-blood complete blood count (CBC), IgG enzymelinked immunosorbent assay (ELISA), serum protein electrophoresis, flow cytometry, and histological examinations of relevant tissues were performed as described previously. Serum creatinine was measured by ELISA using a creatinine assay kit (#ab65340, Abcam, Cambridge, MA) according to the manufacturer's protocol.

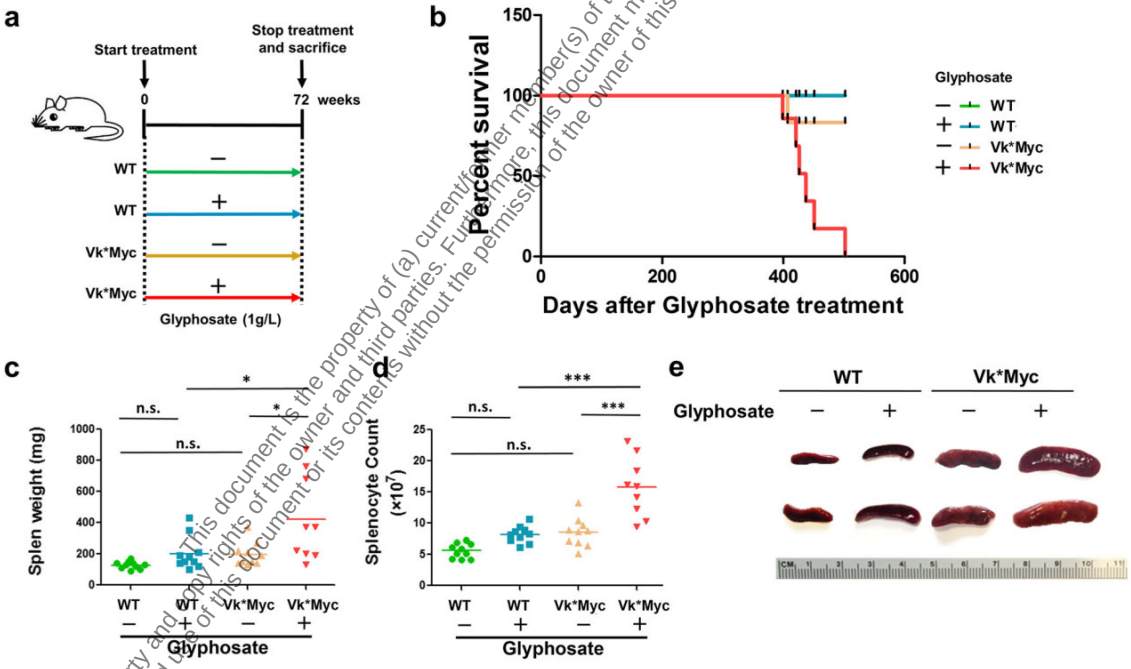
Western blotting analyses; Mouse tissues were processed for Western blotting. The antibodies were from Cell Signaling Technology (Danvers, MA, USA): AID (L7E7) (#4975) and β-actin (#3700). Blotting was run with 3 technical replicates. Horseradish peroxidase- conjugated anti-rabbit or anti-mouse IgG was used as the secondary antibody.

Statistics; Statistical analysis was carried out using GraphPad InStat 3 software (GraphPad Software, Inc., San Diego, CA, USA). The statistical significance between the groups was determined by one-way or two-way analysis of variance (ANOVA) with the appropriate post hoc testing using Tukey's test. Statistical significance was accepted at $P \leq 0.05$. All data are shown as mean ± SEM unless otherwise indicated.

Results

*Chronic glyphosate exposure reduces survival and induces splenomegaly in Vk*MYC mice*; Eight-week-old Vk*MYC mice and their WT littermates were provided 1.0 g/L glyphosate in drinking water for 72 weeks, and animals were monitored at regular intervals before sacrifice (Figure 5.5.2-6a). Glyphosate significantly affected the health of Vk*MYC mice, all of which had to be euthanized by week 72 (Figure 5.5.2-6b). Surviving mice in other groups were sacrificed at week 72 (at age 80 weeks) for necropsy. Inspection of organs revealed a marked increase in spleen weight and size in Vk*MYC mice treated with glyphosate compared to the other 3 groups (Figure 5.5.2-6c, e). Glyphosate significantly augmented the splenocyte number in Vk*MYC mice (Figure 5.5.2-6d). Findings indicate that glyphosate induces splenomegaly in both WT and Vk*MYC mice.

Figure 5.5.2-6: Glyphosate reduced survival and induced splenomegaly in Vk*MYC mice. a Schematic diagram of the chronic glyphosate exposure regimen in 4 groups of mice. b The percentage of mice surviving under glyphosate exposure. The line (blue) to indicate untreated WT mice aligned directly with that for WT treated mice and so was not visible. c Mouse spleen weight at sacrifice. d The total number of splenocytes per spleen from mice at sacrifice. e Representative images of spleens from 4 groups (2 per group).



*Hematological abnormalities occur in Vk*MYC mice with chronic glyphosate exposure*; As illustrated in Fig. 2a, untreated Vk*MYC mice exhibited higher IgG levels than untreated WT mice. Upon glyphosate exposure, WT mice showed moderate yet steady increasing in IgG levels, suggesting that glyphosate induces benign monoclonal gammopathy, a mouse equivalent to human MGUS. Vk*MYC mice receiving glyphosate had greater IgG elevation, and by week 30, IgG levels jumped to 11.78 g/L, more than 5-fold the 2.07 g/L observed in untreated Vk*MYC mice. From week 36 to week 72, the mean IgG level was significantly higher in treated WT and Vk*MYC mice compared to the untreated control groups, and

Vk*MYC mice, treated or untreated, had higher IgG levels than their WT counterparts. Overt MM diagnosis was determined by serum protein electrophoresis (SPEP) analysis to detect the M-spike, which is a significant IgG monoclonal peak. SPEP results showed that Vk*MYC mice treated with glyphosate had a clear M-spike, whereas weaker M-spike was observed in glyphosate- treated WT mice. No clear M-spike was present in the untreated WT mice or Vk*MYC mice (Fig. 2b). This is the direct *in vivo* evidence that glyphosate exposure leads to M-spike, a cardinal hematological abnormality consistent with MM. Hematological abnormalities were present in glyphosate treated mice as compared to untreated control mice (Fig. 2c–i). Data support the notion that glyphosate induces multiple hematological abnormalities characteristic of MM in mice.

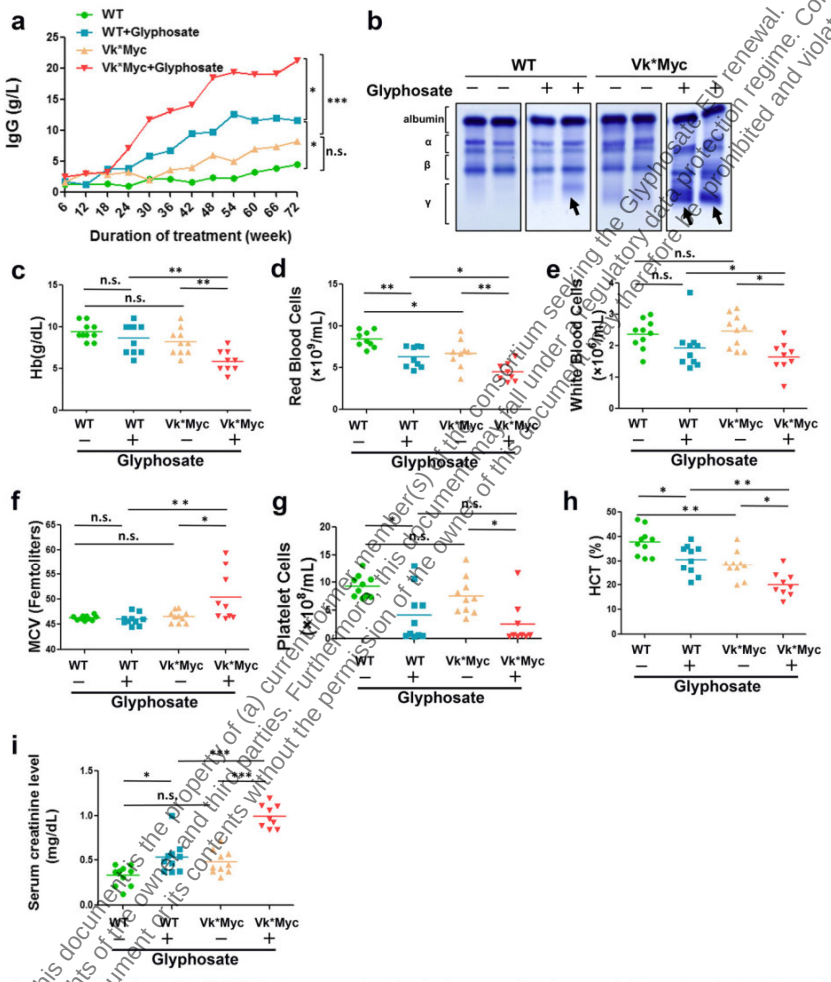


Fig. 2. Hematological abnormalities found in Vk*MYC mice treated with glyphosate. **a** Total serum IgG in mice during 72 weeks of glyphosate treatment. Mouse blood samples were collected and assayed for IgG every 6 weeks. **b** Immunoglobins from mice as determined by SPEP at week 72. Arrows indicate IgG clonal peaks (M-spike; γ-globulin peak). SPEP was performed for all mice in each group, and representative results of 2 mice per group are shown. **c**–**h** Complete blood cell counts in mice. Hemoglobin concentration (Hb, **c**), red blood cell count (**d**), white blood cell count (**e**), mean red cell volume (MCV, **f**), platelet cell count (**g**), and hematocrit (HCT, **h**) are shown. **i** Total serum creatinine in mice at week 72. The horizontal lines indicated the mean value. Data were analyzed by two-way ANOVA (**b**) or one-way ANOVA (**a**, **d**, **e**). $n = 10$ mice per group

*Vk*MYC mice chronically exposed to glyphosate develop progressive plasma cell neoplasms;* Plasma cells exhibit CD138hi B220–(high CD138 expression without B220 expression). Flow cytometric analyses of cells harvested from the spleens and bone marrow showed expansion of plasma cells in mice under glyphosate exposure. A marked increase in the numbers of CD138hi B220– cells was detected in both WT and Vk*MYC mice treated with glyphosate (Fig. 3a). These data demonstrate that glyphosate treatment expands the plasma cell population in the spleen and bone marrow in both WT and Vk*MYC mice.

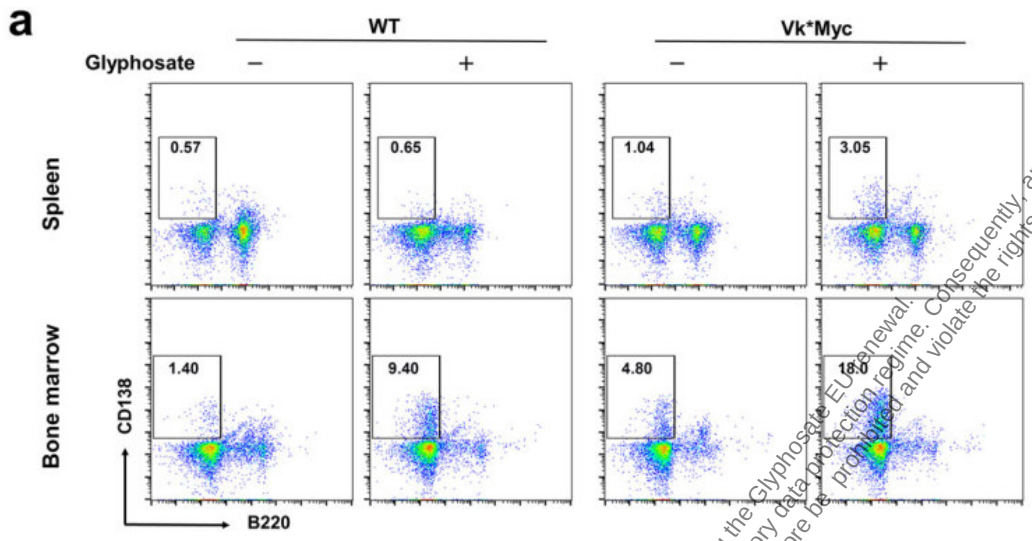

Fig. 3 Glyphosate-treated Vk*MYC mice developed progressive plasma cell neoplasms. **a** Representative flow cytometry plots detecting cell surface markers CD138 (*Y*-axis) and B220 (*X*-axis) in splenocytes (upper panel) and bone marrow cells (lower panel). The numbers on the axes denoted the $\log_{10}$ values of fluorescence. The numbers in the inserts show the percentage of $CD138^{high}B220^{-}$ cells in the entire cell population.

Chronic glyphosate exposure triggers multiple organ dysfunction; To determine whether target organ damage occurred in glyphosate-treated mice, the femoral shaft, spleen, liver, lung, and kidney were sectioned and stained with hematoxylin and eosin (H&E). Severe destructive osteolytic bone lesions in the femoral shaft were readily detectable in glyphosate-treated Vk*MYC mice. Treated WT mice showed smaller bone lesions. No lesions were observed in the control groups (Fig. 4a). Plasma cells with a perinuclear clear zone and eccentric round nucleus were observed in glyphosate-treated WT and Vk*MYC mice (Fig. 4b, c). Next, the histopathologic changes in the liver, lung, and kidney were analyzed. In glyphosate-treated mice, hepatic fibrosis and collagen deposition were observed in Vk*MYC mice, whereas WT mice showed less severe liver damage; the 2 control groups had normal hepatic tissue architectures (Fig. 4d). The lungs in treated Vk*MYC mice were severely damaged, with large distal air spaces filled by lymphocytes, neutrophils, cell debris, and hyperplastic pneumocytes; those from untreated WT mice had normal alveolar spaces and alveolar septa lined with normal pneumocytes. The lungs from treated WT mice and untreated Vk*MYC mice showed an intermediate phenotype (Fig. 4e). Renal tubular obstruction by large casts, indicative of necrotic tubular cells, were detected in glyphosate-treated WT and Vk*MYC mice, but not in the untreated groups; there were more and larger casts in treated Vk*MYC kidneys than in WT kidneys (Fig. 4f). Taken together, these data indicate that glyphosate treatment damages multiple organs in both WT and Vk*MYC mice with more severe damage occurring in Vk*MYC mice.

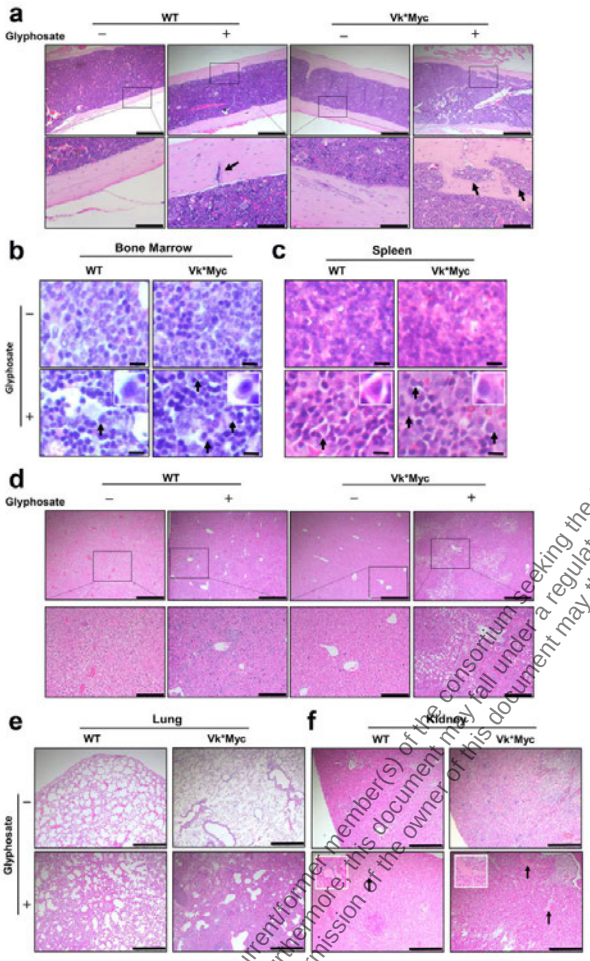

Fig. 4 Glyphosate led to multiple organ dysfunction. **a** Histological evaluation of bone morphology from 4 groups of mice. Bone lytic lesions (indicated by arrows) were detected in the femoral shaft of Vk*MYC mice treated with glyphosate. Scale bar = 500 μm (top) or 100 μm (bottom). **b** Infiltrating plasma cells in the bone marrow of glyphosate-treated mice. Scale bar = 20 μm. Arrows pointed to plasma cells. **c** Infiltrating plasma cells in the spleen of glyphosate-treated mice. Scale bar = 20 μm. Arrows point to plasma cells. **d** Collagen deposition in the liver was observed in glyphosate-treated Vk*MYC mice. $n = 10$ mice per group. All panels show 1 representative image each from 4 groups of mice unless otherwise indicated

Chronic glyphosate exposure induces AID upregulation; To investigate the underlying mechanisms of glyphosate-mediated MGUS induction and MM progression, expression of activation-induced cytidine deaminase (AICDA, also known as AID) in mice treated with 1.0 g/L glyphosate for 72 weeks was examined. It was found that AID was upregulated in both the bone marrow and the spleen of WT and Vk*MYC mice (Fig. 5a).

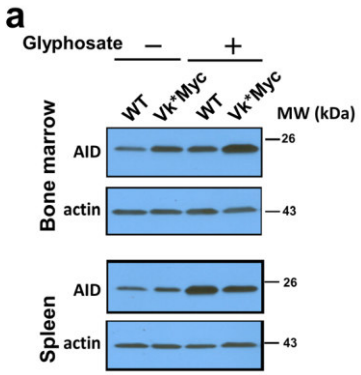

Fig. 5 Glyphosate-induced AID upregulation. **a** Western blotting analysis of mice treated with 1.0 g/L of glyphosate for 72 weeks.

Acute glyphosate exposure induces AID upregulation; To determine the acute effect of glyphosate, 8-week-old WT and Vk*MYC mice were treated with increasing doses of glyphosate (1, 5, 10, and 30 g/L) in drinking water for 7 days. This acute treatment neither increased spleen weight nor affected body weight significantly. Next, expression of AID in the spleen, bone marrow, and lymph nodes were analysed. It was found that AID was upregulated in a glyphosate dose-dependent manner in the spleen and bone marrow of WT and Vk*MYC mice treated with 10 and 30 g/L of glyphosate (Fig. 5c). Given the role of AID in MM pathogenesis in the context of its capacity to induce mutations and chromosome translocations, these results from mice with chronic and acute glyphosate treatment support an AID mediated mutational mechanism in the etiology of MGUS and MM under glyphosate exposure.

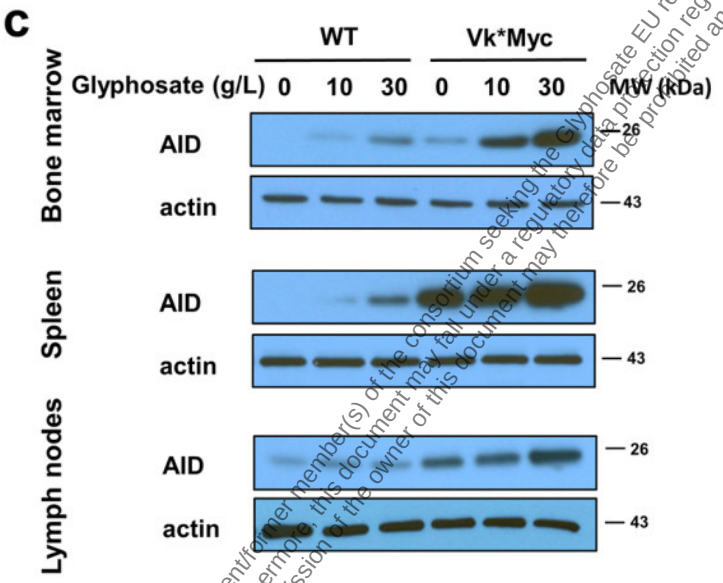

Fig. 5 c Western blotting analysis of mice treated with glyphosate for 7 days. One representative mouse

Discussion

In this study, it was demonstrated that glyphosate induces benign monoclonal gammopathy (mouse equivalent to MGUS in human) in WT mice and promotes MM progression in Vk*MYC mice. In Vk*MYC mice, glyphosate causes hematological abnormalities like anemia and multiple organ dysfunction like lytic bone lesions and renal damage, which are hallmarks of human MM. Beyond epidemiology and animal models, the mechanism of action is the third pillar required to define a compound as a carcinogen. Numerous studies have revealed that glyphosate may induce DNA damage, oxidative stress, inflammation, and immunosuppression, as well as modulate cell proliferation and death and disrupt sex hormone pathways. However, these mechanistic studies have failed to explain why glyphosate exposure is only positively associated with MM and NHL. Our results demonstrate that glyphosate treatment, either at a chronic low dose or acute high doses, upregulates the expression of AID in the bone marrow and spleen of both WT and Vk*MYC mice. The data disclose, for the first time, that glyphosate elicits a B cell-specific mutational mechanism of action in promoting carcinogenesis, as well as offering experimental evidence to support the epidemiologic finding regarding its tissue specificity in carcinogenesis (i.e. only increasing the risk for MM and NHL). The "acceptable daily intake (ADI)" of glyphosate currently allowed in the USA, defined as the chronic reference dose as determined by EPA, is 1.75 mg/kg body weight/day; an average adult male or female in the USA who weighs 88.8 or 76.4 kg and drinks 2 L (8 glasses) water daily containing 77.7 (for male) or 66.9 (for female) mg/L glyphosate would reach the ADI. A dose of 1,000 mg/L glyphosate in drinking water (~ 15-fold the ADI) was chosen in this study, which caused significant adverse effects and accelerated MM progression in Vk*MYC mice, i.e. animals predisposed to MM.

Conclusion
The data provide *in vivo* evidence to support that glyphosate induces MGUS and promotes disease progression to MM. A B cell-specific mutational mechanism for glyphosate exposure that increases MM and NHL risk was uncovered, providing a molecular basis for human epidemiological findings.

3. Assessment and conclusion

Assessment and conclusion by applicant:
The objective of this study was to investigate the pathogenic role of glyphosate in multiple myeloma using Vk*MYC mice. The study did demonstrate the ability of glyphosate to impact measured parameters in the tested models. However, this study is not appropriate for human health risk assessment. The number or animals per group was below the recommended number for guideline toxicity studies and to perform sufficient statistical analysis. Only one dose level was used in the chronic study. It was not possible to correlate effects with a glyphosate dose-response as the water consumption (and therefore test substance intake) of animals was not provided and it is therefore impossible to calculate a dose on a mg/kg bw basis for risk assessment.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used was not characterized, only one dose was considered for the chronic study and the number of animals used per group was either too low (acute study) or not reported (chronic study).

Assessment and conclusion by RMS:

Reliability criteria for *in vivo* toxicology studies

Publication: Wang *et al*., 2019	**Criteria met? Y/N/?**	**Comments**
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines	N	
Study performed according to GLP	N	
Study completely described and conducted following scientifically acceptable standards	Y?	
Test substance		
Test material (Glyphosate) is sufficiently documented and reported (i.e. purity, source, content, storage conditions)	N	Purity not reported. Source: Sigma-Aldrich, St Louis, USA.

Guidelines followed in study	Not applicable
Deviations from current test guideline	Not applicable
GLP/Officially recognised testing facilities	Not applicable
Acceptability/Reliability:	Yes/Reliable/Reliable with restrictions

2. Full summary of the study according to OECD format

In 2005, an evaluation of glyphosate and cancer risk was conducted in the Agricultural Health Study (AHS) (DeRoos *et al*. 2005). This evaluation considered glyphosate use reported at enrollment (1993–1997) and included 2,088 cancers diagnosed between enrollment and 2001. No statistically significant associations were found for any cancer site. For NHL, the relative risk (RR) adjusted for age, personal factors and other pesticides was 1.1 (95 % CI 0.7-1.9) and there was no trend of increasing RRs with increasing frequency of glyphosate. For multiple myeloma, the overall adjusted RR was 2.6 (95 % CI 0.7 – 9.4) and the assessment of RR by frequency of glyphosate use did not evidence a significant trend. Andreotti *et al*. 2018 updated the 2005 AHS publication by DeRoos *et al*. (2005), extending cancer incidence follow-up through

2012 in North Carolina and 2013 in Iowa and incorporating additional exposure information from a follow-up questionnaire. The authors also dealt with missing information through imputation and conducted sensitivity analyses to address the potential for various types of bias in their primary analyses. This 2018 publication includes a total of 7,290 cancers, 3.6 times as many as in the earlier publication. The median lifetime days of glyphosate use for cohort members who reported glyphosate use (83 % of the cohort) was 48 days (interquartile range (IQR) 20 to 166 days). The authors found no evidence of an association between glyphosate use and risk of any solid tumour, NHL (RR 0.87 (95 % CI 0.64, 1.20 in the highest intensity weighted exposure quartile, p_{trend} 0.95), or multiple myeloma (RR 0.87, 95 % CI 0.45, 1.69 highest quartile, p_{trend} 0.84). They found a moderately elevated RR for acute myelogenous leukaemia that was not statistically significant (RR 2.44, 95 % CI 0.94, 6.32, p_{trend} = 011). The findings for cancer types were consistent across different exposure metrics, in various sensitivity analyses, and for lagged exposure analyses meant to address cancer induction-latency.

Materials and methods

Study design

Briefly, 57,310 individuals seeking licenses to apply restricted-use pesticides were enrolled between 1993 and 1997. Of the enrolled participants, 63 % completed a follow-up phone interview approximately five years after enrollment (1999–2005). Incident cancer diagnoses were ascertained *via* linkage to cancer registries in Iowa (through 2013) and North Carolina (through 2012). Cancer diagnoses were classified according the International Classification of Disease– Oncology, 3rd Revision. Subtypes of lymphoid malignancies were defined according to the Surveillance, Epidemiology, and End Results Program Lymphoma Subtype Recodes. According to this updated classification of lymphoid malignancies, multiple myeloma was included in the analyses as a subtype of non-Hodgkin's lymphoma. Vital status was ascertained *via* state mortality registries and the National Death Index, and state of residence was regularly updated using various government databases.

Exposure assessment

Lifetime use of glyphosate and 49 other pesticides was ascertained at enrollment and in the follow-up questionnaire. At enrollment, applicators reported the number of years and days per year each pesticide was used, while at follow-up applicators reported the number of days each pesticide was used in the most recent year farmed. Using this information, three metrics of cumulative lifetime exposure were created for each pesticide: ever/never use, lifetime days of use (days per year multiplied by the number of years), and intensity-weighted lifetime days (lifetime days multiplied by an intensity score). The intensity score was derived from an algorithm based on literature-based measurements and information provided by the applicator, specifically whether the participant mixed or applied pesticides, repaired pesticide-related equipment, used personal protective equipment, and application method used. For participants who did not complete the follow-up questionnaire (37 %), multiple imputation was used to impute pesticide use since enrollment. Factors used to impute pesticide use included demographic data and medical history, as well as factors related to farm characteristics and reported pesticide use at enrollment.

Statistical analysis

For this analysis, individuals who had a history of cancer at enrollment (n=1096), did not live in North Carolina or Iowa (n=343), or did not report whether they had used glyphosate or not at enrollment (n=1620) were excluded, resulting in an analytic sample of 54,251 licensed farmers and applicators. Individuals accumulated person-time from enrollment until the earliest of the following events: movement out of state, diagnosis of cancer, death, or end of the follow-up period (December 31, 2012 in NC, December 31, 2013 in IA). Poisson regression was used to calculate incidence rate ratios (RRs) and 95 % confidence intervals (CIs), and PROC MIANALYZE was used to obtain the appropriate variance for the imputed data. All statistical significance tests were two-sided and considered to be statistically significant when $p \leq 0.05$. RRs for total cancer and for cancer sites with at least 20 exposed cases were evaluated. For analyses by exposure level, based on the distribution among all cancer cases, cumulative lifetime days and intensity-weighted lifetime days of glyphosate exposure into quartiles, tertiles, or the median were categorized, such that there were at least five exposed cases in each category. Linear trend was evaluated according to the

Wald test using the median of each exposure category as a continuous variable. Risk estimates were adjusted for attained age (continuous), cigarette smoking status (never, former, current), alcohol drinks per month (none, ≤ 6 per month, ≥ 7 per month), family history of any cancer (yes, no), state of recruitment (North Carolina, Iowa), and the five pesticides most highly correlated with glyphosate based on lifetime days and intensity-weighted lifetime days (r > 0.4: atrazine, alachlor, metolachlor, trifluralin, 2,4-D). Lagged exposure was also evaluated allowing for 5, 10, 15, or 20 years to address the induction-latency period for specific cancers. Other potential confounding factors were calculated, including body mass index (BMI; <25, 25–<30, _30 kg/m^2) and pack-years of cigarettes smoked (tertiles of use among former and current smokers). The numbers of women and nonwhites were small, precluding adjustment for sex and race for most cancer sites; in sensitivity analyses, the risks in men and whites alone were assessed. For lymphohematopoietic cancers, RRs were additionally adjusted for occupational exposure to solvents, gasoline, x-ray radiation, and engine exhaust, and pesticides linked to lymphohematopoietic malignancies in previous AHS analyses (lindane, DDT, diazinon, terbufos, and permethrin). The risk of NHL excluding multiple myeloma was calculated for comparison with previously published studies. Lastly, sensitivity analyses were conducted to evaluate the impact of including additional exposure information.

Results

Among 54,251 participants, 44,932 (82.8 %) reported ever using glyphosate at enrollment or during follow-up. Among the participants who used glyphosate, the median lifetime days of use was 48 (interquartile range [IQR] = 20–166 days), and the median lifetime years of use was 8.5 years (IQR = 5–14 years). A total of 7,290 incident cancers were diagnosed during the follow-up period. Among the participants who used glyphosate and were diagnosed with cancer during follow-up (n=5,779), the median lifetime days of use was 38.75 (IQR = 13.75–108.5 days), and the median lifetime years of use was 8.0 (IQR = 3.5–13.0). Selected characteristics of the study participants by glyphosate use are presented in Table 1. Risk ratios for intensity-weighted lifetime days of glyphosate use and cancer risk are shown in Table 2. Glyphosate use was not associated with total cancer or with lymphohematopoietic malignancies. There also was no evidence for positive associations with NHL (RR in the highest intensity weighted days of glyphosate use quartile = 0.9 (95 % CI 0.6 – 1.2)), multiple myeloma ($RR_{quartile\ 4}$ = 0.9, 95 % CI 0.5 – 1.7) or for any NHL subtype. Although not statistically significant, the authors observed an elevated RR for acute myeloid leukemia (AML; n = 57 exposed cases) among applicators in the highest quartile of intensity weighted glyphosate use compared with never users (n = 18 cases, RR.2.4, 95 % CI = 0.9 to 6.3, P_{trend} =.11). The results based on intensity weighted days of use were very similar to results based on unweighted days of use.

The impact of lagging exposure on risk estimates for lymphohematopoietic cancers was evaluated for intervals of 5, 10, 15 and 20 years. The patterns of risk for lagged exposures were similar to those for unlagged exposures.

Conclusion

In conclusion, the authors found no evidence of an association between glyphosate use and risk of any solid tumor, NHL, or multiple myeloma. They found an elevated RR for AML that was not statistically significant, but that merits evaluation in AHS updates or other studies. This findings across cancer types were consistent across different exposure metrics, in various sensitivity analyses, and for lagged exposure analyses meant to address cancer induction-latency.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The AHS is an ongoing prospective cohort study of glyphosate and other pesticides. It was initiated in 1993 and has been ongoing for more than 25 years. Researchers from the US National Cancer Institute and other government agencies initiated the AHS as a prospective cohort study to eliminate the possibility of case-recall bias – an intractable potential bias in case control studies that rely on self-reported exposure information. Crump (Risk Analysis DOI:10.1111/risa.13440) has recently illustrated that the results from the glyphosate case-control studies align closely with what would be expected from case recall bias.

In addition to obviating concerns about case-recall bias, the Andreotti *et al*. publication is noteworthy on several counts. First, the frequency of glyphosate use by participants (median = 48 days, IQR 20 to 166 days) vastly exceeds that in the glyphosate case-control studies. In those studies the most frequent days of use category is > 10 days (Eriksson M, *et al*. Int J Cancer. 2008; 123:1657-1663), while most of the case control studies' primary analyses were based on 1 day or more of use in a lifetime. Second, the participants in the AHS were licensed pesticide applicators who were considered by the authors to be very capable to report pesticide use accurately compared with other study populations. Third, the analyses by Andreotti *et al*. controlled for a multitude of personal factors and for other pesticides in addition to incorporating a wide range of sensitivity and lagged analyses (allowing for up to 20+ years induction-latency). No other study has evaluated the relationship between glyphosate use and cancers as extensively. The AHS is, by far, the most informative and relevant study epidemiologic study for glyphosate to date. The authors found no evidence of an association between glyphosate use and risk of any solid tumour, NHL, or multiple myeloma.

Accordingly, given the AHS results for NHL among those with extensive glyphosate use (n = 111 exposed cases, RR = 0.9, 95 % CI 0.6 – 1.2), it is unlikely that the positive associations for glyphosate and NHL in some case control studies are valid. As follow-up of the AHS cohort continues, it remains to be seen whether subsequent results will identify relationships between individual cancers and glyphosate use that are relevant for risk evaluations.

Assessment and conclusion by RMS:

Reliability Criteria: Epidemiology studies

Publication: Andreotti G. *et al.,* 2018	**Criteria met? Y/N/?**	**Comments**
Study Design		
Adequate study design given study objectives	Yes	
Appropriate study population to address potential glyphosate-related health outcomes	Yes	Most appropriate population studied to date. Highest frequency of glyphosate use by far.
Exposure studied		
Exposure to formulations with glyphosate as a.s.	Yes	
Exposure to formulations with other a.s.	Yes	
Exposure to other farm exposures	Yes	
Study Conduct/analysis		
Adequate description of study population	Yes	
Adequate description of exposure circumstances	Yes	
Comparable participation by groups being compared	Yes	
Information provided by proxy respondents	No	
Adequate statistical analysis	Yes	Very comprehensive
Adequate consideration of personal confounding factors	Yes	Very comprehensive
Adequate consideration of potentially confounding exposures	Yes	Very comprehensive
Overall assessment		
Reliable without restrictions	Yes	Most reliable epidemiology study for glyphosate users versus non-users.
Reliable with restrictions	Yes	Certain analyses are limited: dose is not known, only frequency of use. So, "dose response" analyses must be interpreted cautiously.
Not reliable	No

2. Full summary of the study according to OECD format

Three case-control studies in the United States and Canada were pooled to create the North American Pooled Project (NAPP) to investigate associations between pesticide use and haematological cancer risk. This analysis used data from 547 MM cases and 2700 controls. Pesticide use was evaluated as follows: ever/never use; duration of use (years); and cumulative lifetime- days (LD) (days/year handled 3 years of use). Odds ratios (ORs) and 95 % confidence intervals (CIs) were estimated using logistic regression adjusted for age, province/state of residence, use of proxy respondents and selected medical conditions.

Materials and Methods

Study population - The North American Pooled Project (NAPP) is comprised of three population-based incident case-control studies conducted by the U.S. National Cancer Institute in Kansas, Iowa/Minnesota and Nebraska in the 1980s, and the Cross Canada Study of Pesticides and Health (CCSPH), a population-based incident case-control study that was conducted in Quebec, Ontario, Manitoba, Saskatchewan, Alberta and British Columbia in the early 1990s. All 4 studies aimed to investigate the effects of pesticides and other agricultural exposures on the risk of lymphatic and hematopoietic cancers. The present analysis is restricted to a subset of three NAPP studies conducted in Iowa, Nebraska and Canada (CCSPH) where multiple myeloma (MM) cases were recruited. The study design and data collection in the CCSPH were modeled after the U.S. studies, making the data amenable to pooling. Eligible participants included white men aged 30 years or older in Iowa, white men and women aged 21 years or older in Nebraska, and men aged 19 years or older in Canada. Deceased participants were considered eligible in Iowa and Nebraska, but not in the Canadian study. Proxy respondents were used on behalf of deceased subjects in Iowa and Nebraska, and were permitted in Iowa, Nebraska, and Canada for participants requiring assistance due to illness or disability. Incident MM cases were identified using state and provincial cancer registry records, with the exception of Nebraska and Quebec, where cases were recruited from hospitals. Population-based controls were identified using random digit dialing (all studies), Medicare records and state mortality files (Iowa and Nebraska), health insurance records (Alberta, Saskatchewan, Manitoba and Quebec), telephone listings (Ontario) and voter lists (British Columbia). Cases and controls were frequency-matched to the overall case distribution by age (62 years in Nebraska and Canada, 65 years in Iowa), vital status and year of death (if applicable), sex (Nebraska) and province of residence (Canada). The participation rates in the MM subset of NAPP studies were modest for Canadian controls (48 %) and higher in Iowa (78 %) and Nebraska (85 %). Participation rates were higher for cases in Canada (58 %), Iowa (84 %) and Nebraska (88 %).

Exposure assessment - A set of *a priori* pesticides to be investigated in this analysis included agents that showed positive (significant or nonsignificant) associations in the earlier U.S. and Canadian studies. Pesticides that met these criteria were 2,4-D, captan, carbaryl, chlordane, DDT, glyphosate, lindane, malathion, methoxychlor, permethrin and the pyrethrins. Self-reported information on pesticide use, farming activities and demographic characteristics were obtained through standardized interviews with participants. Individuals who provided an affirmative answer to general questions about pesticide use or exposure to substances within broad groups (i.e. insecticides, herbicides, fungicides) were subsequently asked more detailed follow-up questions regarding specific agents, including the frequency and duration of exposure. Participants who did not report any pesticide use were classified as unexposed. Among individuals reporting pesticide use, missing information for duration or frequency of exposure was treated

as missing or unknown. Information on duration of pesticide use (years) was collected in all studies, whereas frequency information (days per year) was only collected in Canada and Nebraska. The data from Nebraska were excluded from the analysis since the number of exposed cases for pesticides of interest was low and the proportion of missing data was prohibitively high (>40 %).

Exposure metrics - Associations were examined for dichotomous exposure (ever/never pesticide use) and by major chemical classes i.e. phenoxy herbicides, and organochlorine, organophosphate and carbamate insecticides. The duration of exposure was evaluated for each individual pesticide using years of self-reported use. Cumulative exposure was investigated using a composite lifetime days (LD) metric, defined as: LD = years of pesticide use x days/year of pesticide use. Analyses of cumulative exposure were restricted to the Canadian subset of the NAPP data, where sufficient information about both years and days/year was available. For subjects with missing information for the duration of pesticide use, simple conditional imputation was carried out. Age- and state/province-specific median values for years and days/year were assigned to participants classified as exposed based on the ever/never metric. Imputed values were only assigned if <35 % of exposure duration data were missing among cases, and if the proportions of missing data differed by <20 % between cases and controls.

Statistical analysis - Descriptive analyses were performed on potential confounders identified from the literature including age, province/state of residence, use of a proxy respondent, farming history (ever lived or worked on a farm) and personal medical history. Covariates that were significantly ($p < 0.05$) associated with MM or those that produced meaningful changes (≥5 %) in the OR estimates were retained in the final models. Unconditional logistic regression was used to calculate odds ratios (OR) and 95 % confidence intervals (CI) for pesticide exposure variables with adjustment for age, province/state of residence, use of proxy respondent, and ever being diagnosed with any allergy, hay fever, or rheumatoid arthritis. For all analyses of individual pesticides, the referent population consisted of subjects who did not report any pesticide use, or those who indicated that they had not used that specific agent. Duration of pesticide exposure and cumulative LD were modeled as ordinal variables and linear trends were examined (*p*-trend). Cut-offs for categories were based on the median duration and LD among cases and controls for each pesticide. The use of proxy respondents was also considered as an effect modifier and sensitivity analyses were conducted excluding information provided by proxy respondents All analyses were performed using SAS version 9.3.

Results

The analysis included a total of 587 MM cases and 3,588 controls from Iowa, Nebraska and six Canadian provinces. Female cases ($N = 40$) and female matched controls ($N = 707$) contributed by the Nebraska study were excluded due to the very low prevalence of pesticide use among females. The youngest MM case in the NAPP dataset was 31 years old and, therefore, the controls of an age of 30 years and younger were excluded ($N = 181$) to maintain a comparable distribution of age between cases and controls. The final analysis included 547 male cases and 2,700 male controls. Among the participants, cases were older than controls. This was expected since a common age-matched control group was used for all cancer sites in the NAPP and the majority of MM cases are typically diagnosed at slightly older ages (>65 years) than non-Hodgkin lymphoma and Hodgkin lymphoma cases. Proxy respondents were used for 35 % of the cases and 28 % of the controls overall. Associations of demographic characteristics and medical history covariates with MM were modeled using logistic regression, with adjustment for age (in years) and province or state of residence. A history of any type of cancer among first-degree relatives was significantly associated with MM risk. However, having a first-degree relative with any lymphatic or haematopoietic cancer, including MM, was not associated with MM. A number of conditions associated with stimulation of the immune system showed statistically significant inverse associations with MM risk. In this summary only data on glyphosate are reported.

Pesticide exposure (ever/never in the NAPP) - For the "never" use of glyphosate 502 (91.8 %) cases and 2,504 (92.7 %) controls and for the "ever" use of glyphosate 45 (8.2 %) cases and 196 (7.3 %) controls were identified. The adjusted OR was 1.29 (95 % CI 0.9-1.85). When proxy respondents were excluded then the adjusted OR was 1.07 (95 % CI 0.69-1.66).

Pesticide exposure relative to the years of exposure (Iowa and Canada subset of the NAPP) – For no exposure to glyphosate 471 (91.4 %) cases and 1,832 (91.7 %) controls, for up to 3 years of exposure to glyphosate 22 (4.3 %) cases and 87 (4.3 %) controls and for more than 3 years 22 (4.3 %) cases and 80 (4.0 %) controls were identified. The adjusted OR was 1.30 (95 % CI 0.79-2.16) for up to 3 years of exposure and 1.34 (95 % CI 0.80-2.23) for more than 3 years of exposure. The trend was not statistically significant (p = 0.16). When the adjusted OR was taken with exclusion of proxy respondents it was 1.19 (95 % CI 0.67-2.11) for up to 3 years of exposure and 0.95 (95 % CI 0.50-1.83) for more than 3 years exposure. The trend was not statistically significant (p = 0.90).

Pesticide exposure relative to the number of lifetime days (LD) (Canadian subset of the NAPP) - For no exposure to glyphosate 310 (90.6 %) cases and 1,228 (91.0 %) controls, for up to 6 LD of exposure to glyphosate 18 (5.3 %) cases and 65 (4.8 %) controls and for more than 6 LD 14 (4.1 %) cases and 56 (4.2 %) controls were identified. The adjusted OR was 1.35 (95 % CI 0.76-2.40) for up to 6 LD of exposure and 1.11 (95 % CI 0.59-2.07) for more than 6 LD of exposure. The trend was not statistically significant (p = 0.48). When the adjusted OR was taken with exclusion of proxy respondents it was 1.43 (95 % CI 0.76-2.70) for up to 6 LD of exposure and 0.94 (95 % CI 0.44-1.99) for more than 6 LD of exposure. The trend was not statistically significant (p = 0.74).

Discussion and Conclusions

Despite the increase in the overall sample size resulting from pooling data from the CCSPH and U.S. NCI studies, the numbers of exposed participants were still low for some pesticides, and information for duration or frequency was sparse and not collected in all MM studies. Our ability to investigate the effects of high levels of exposure was further limited, since few participants reported frequent and long- term pesticide use. Exposure misclassification due to the use of proxy respondents may also influence results. Studies have shown that farmers may be able to recall pesticide use better compared to nonfarmers, and certain types of proxy respondents, such as friends and family members who also work in agriculture, may be more likely to recall the use of certain specific pesticides. It should be recognized that a large number of comparisons were made and some of the effect estimates were based on small numbers of exposed cases and controls. Therefore, it cannot be excluded that some of the observed associations may represent chance findings. Despite these limitations, this study has several important strengths. The NAPP is one of the largest pooled case-control studies of agricultural exposures and haematopoietic cancers. This analysis was the first to investigate the association between pesticide exposure and MM risk in a pooled sample of Canadian and American participants. Since similar pesticides were used in both Canada and the United States, it was possible to investigate the effects of these exposures in the NAPP overall. Furthermore, similarities in the design of the case-control studies facilitated successful pooling of these datasets, which afforded a larger sample size for more comprehensive and powerful analyses. Specifically, the investigation of different aspects of pesticide exposure, such as duration of use and cumulative lifetime exposure provided an informative and novel addition to this analysis of pesticide use alone. A further advantage of this study was the extensive medical history information that was collected in the Canadian and U.S. studies. This allowed us to take into account the influence of several conditions that result in sustained stimulation of the immune system, such as rheumatoid arthritis, systemic lupus erythematosus, certain viral infections and allergies, which were inversely associated with MM in our data.

No statistically significant increases in risk of multiple myeloma (MM) associated with self-reported exposure to glyphosate were observed.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Four population-based incident case-control studies (3 US studies and one Canadian study) pooled in the North American Pooled Project (NAPP) aimed to investigate the effects of pesticides and other agricultural exposures on the risk of lymphatic and hematopoietic cancers. The present analysis is restricted to a subset of three NAPP studies (Iowa, Nebraska and Canada) where multiple myeloma

(MM) cases were recruited. Self-reported information on pesticide use, farming activities and demographic characteristics was collected and the odds ratios (OR) were calculated for "ever/never" exposure, years of exposure and cumulated lifetime days of exposure to glyphosate with and without exclusion of proxy respondents. The result is that no statistically significant increases in risk of multiple myeloma (MM) associated with self-reported exposure to glyphosate were observed.

This publication is considered relevant for glyphosate risk assessment but reliable with restrictions because it concerns pooled case control studies which are subject to recall bias and in which confounding factors could not be ruled out.

2. Full summary of the study according to OECD format

The Relative risks (RRs) for exposed and non-exposed subjects were calculated using Poisson regression; subjects with missing data were not excluded from the main analyses. Using the full dataset adjusted for age and gender the analysis produced a RR of 1.12 (95 % CI 0.50 to 2.49) for ever-use of glyphosate. Additional adjustment for lifestyle factors and use of ten other pesticides had little effect (RR 1.24, 95 % CI 0.52 to 2.94). There were no statistically significant trends for multiple myeloma risks in relation to reported cumulative days (or intensity weighted days) of glyphosate use. The doubling of risk reported previously arose from the use of an unrepresentative, restricted dataset and analyses of the full dataset provides no convincing evidence in the AHS for a link between multiple myeloma risk and glyphosate use.

Materials and Methods

The secondary data file which served as a basis for this study was provided by researchers of the Agricultural Health Study (AHS) taking care of the privacy of the participants. AHS researchers supplied an informative description of the file and the file was found to be internally consistent as well as consistent with data descriptions supplied earlier. All subjects gave their informed consent for inclusion before they participated in the AHS study and ethics approval for the original data collection by AHS researchers was obtained from the Institutional Review Board of the National Institutes of Health. This secondary analysis was conducted in accordance with the Declaration of Helsinki and the protocol was approved by the University of Birmingham Science, Technology, Engineering and Mathematics Ethical Review Committee.

Data on lifestyle factors and use of pesticides were collected from 57,311 private and commercial pesticide applicators from Iowa and North Carolina. Previous analyses were carried out on three subsets of data: Set 1 comprised 54,315 applicators excluding those with any cancers diagnosed before enrolment, applicators lost to follow-up, who had missing data for age at enrolment, or who provided no information on whether they had ever used glyphosate. Set 2 comprised 49,211 applicators and further excludes applicators with missing data on level of education, smoking history, or use of alcohol. Set 3 comprised 40,719 applicators and further excludes applicators with missing data on either use or estimated cumulative exposure days for 2,4-D (2,4-dichlorophenoxy acetic acid), alachlor, atrazine, metolachlor, or trifluralin, and missing data on ever-use of benomyl, maneb, paraquat, carbaryl, or diazinon. The objective of this analysis was to examine findings in an as full a dataset as possible and some analyses have also been carried out on a larger fourth set of 55,934 applicators, a category that does not exclude applicators with missing data on ever-use of glyphosate but only applicators with cancers diagnosed before enrolment, applicators lost to follow-up, or who had missing data for age at enrolment.

Poisson regression was used to estimate RRs and 95 % CIs associated with glyphosate exposure metrics, with and without adjustment for other variables. Each variable under analysis was classified into levels or categories. The analytical approach for the full dataset was to have a "not known/missing" category for each variable so that analyses of all available cases could be maintained. However, it was necessary to ensure that there was at least one case of multiple myeloma in each level of each variable for the regression

to successfully calculate RRs. There were no cases of multiple myeloma in those applicators with "unknown use of 2,4-D", such applicators were combined with those reporting "no use" to create a new category of "no claim of use". There were no cases of multiple myeloma in applicators with an "unknown level of education". These applicators were combined with those reporting no education beyond high school. All significance tests were two-tailed and tests for trend (where applicable) were calculated by scoring the levels of a variable and treating the variable as unfactored. All analyses were performed with the EPICURE statistical software, using the double precision DOS version 2.12 of DATAB and AMFIT, dated March 2002.

Results

There were 32 cases of multiple myeloma in Set 1, 26 cases in Set 2, and 22 in Set 3. For the calculation of the RRs there was no adjustment for gender. None of the RRs calculated (RR including statistical adjustment for age at enrolment and RR with additional adjustments) for the three sets is statistically significant and in Set 1, the largest data set, the RR for ever-use of glyphosate is close to unity (RR 1.08, 95 % CI 0.48 to 2.41). The point estimates of risk for the smaller datasets show an approximate doubling of risk irrespective of whether adjustment for other variables is carried out. The largest RR is shown for the fully adjusted model of the smallest dataset (RR 2.79, 95 % CI 0.78 to 9.96).

Estimated risks of multiple myeloma for reported ever-use for the 54,315 applicators in Set 1 (total of 32 cases) were calculated in relation to use of pesticides and other variables (smoking, alcohol consumption, family history of cancer and education). The RR for ever-use of glyphosate, with adjustment for age at enrolment and gender only, is close to unity (RR 1.12, 95 % CI 0.50 to 2.49). The RR for ever-use of glyphosate is little changed with additional adjustment for all 14 other variables (RR 1.24, 95 % CI 0.52 to 2.94).

RR estimates were calculated for multiple myeloma in terms of levels of reported cumulative days of glyphosate use and levels of estimated intensity-weighted exposure days for the 54,315 applicators in Set 1. For each exposure metric three sets of RRs have been calculated: firstly, adjusting for age at enrolment and gender; secondly, with additional adjustment for cigarette smoking, use of alcohol, family history of cancer, and level of education; and thirdly, with additional adjustment for use of ten other pesticides. Two tests for trend were applied to each of these analyses, the first scored the levels of cumulative exposure as 1-4, the second scored the level by mean values. There were no statistically significant trends, but a not statistically significantly elevated RR was shown for the highest category of intensity-weighted exposure days in the fully adjusted model (RR 1.87, 95 % CI 0.67 to 5.27). There were no cases of multiple myeloma in glyphosate users with unknown extent of use.

RR estimates were calculated for multiple myeloma in terms of levels of ever-use of glyphosate, reported cumulative days of glyphosate use, and estimated intensity-weighted exposure days for the 55,934 applicators in Set 4 with a total of 34 cases of multiple myeloma. The risk of multiple myeloma in ever-users of glyphosate was close to unity (RR 1.18, 95 % CI 0.36 to 8.20) and there were no significant trends with either of the two cumulative exposure metrics.

Discussion

This study found no significant trends of multiple myeloma risk with reported cumulative days of glyphosate use and unexceptional point estimates of risk for ever-use of glyphosate. This was irrespective of whether the analyses had adjustment for a few basic variables (age and gender) or adjustment for many other lifestyle factors or pesticide exposures, as long as data on all available pesticide applicators were used. The suspiciously elevated RRs reported previously arose from the use of restricted data sets that, probably by chance, turned out to be unrepresentative. These restrictions would seem to be unnecessary because there is no technical problem in dealing with missing data in Poisson regression. The practice of restricting analyses to subjects with complete data for all variables is, perhaps, a procedure to be carried out with caution as it is clear from this example that such restrictions can lead to misleading findings. It also ignores the fact that findings for missing categories can often be interesting in their own right.

Conclusion
This secondary analysis of AHS data does not support the hypothesis that glyphosate use is a risk factor for multiple myeloma, and suggests that the practice of restricting analyses to subjects with complete data for all variables is perhaps not to be recommended.

3. Assessment and conclusion

Assessment and conclusion by applicant:
In this study the relative risk estimates for exposed and non-exposed applicators were calculated using Poisson regression and subjects with missing data were not excluded from the main analyses. When using the full dataset adjusted for age and gender the analysis produced a RR close to unity for ever-use of glyphosate. Additional adjustment for lifestyle factors and use of ten other pesticides had little effect. This study found no statistically significant trends of multiple myeloma risk with reported cumulative days of glyphosate use and unexceptional point estimates of risk for ever-use of glyphosate. This was irrespective of whether the analyses had adjustment for a few basic variables (age and gender) or adjustment for many other lifestyle factors or pesticide exposures, as long as data on all available pesticide applicators were used. The suspiciously elevated RRs reported previously arose from the use of restricted data sets that, probably by chance, turned out to be unrepresentative.

This publication concerns a secondary analysis of the data from the Agricultural Health Study (AHS) and is considered relevant for the risk assessment of glyphosate and reliable without restrictions because it complies with the reliability criteria of a well conducted epidemiology study.

Assessment and conclusion by RMS:

Reliability criteria for epidemiology studies

Publication: Sorahan T., 2015	**Criteria met? Y/N/?**	**Comments**
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines/practices.		
Study completely described and conducted following scientifically acceptable standards	Y	Secondary analysis of the AHS data
Test substance		
Exposure to formulations with only glyphosate as a.s.		
Exposure to formulations with glyphosate combined with other a.s.		
Exposure to various formulations of pesticides	Y	
Study		
Study design – epidemiological method followed	Y	
Description of population investigated	Y

Not reliable		
This publication concerns a secondary analysis of the data from the agricultural health study and is considered relevant for the risk assessment of glyphosate and reliable without restrictions because it complies with the reliability criteria of a well conducted epidemiology study.		

CA 5.6 Reproductive toxicity

The potential of glyphosate to cause effects on **reproduction** (reproductive performance, fertility, development) was examined in several multi-generation studies. Further, two one-generation studies are available which were considered as supportive data to assess reproductive toxicity. Reliable and relevant publications on reproductive toxicity were also taken into account for hazard assessment.
No specific reproductive toxicity potential was concluded for glyphosate in the previous evaluation (RAR, 2015). A significant decrease in homogenisation-resistant spermatid count and equivocal effects on litter size was observed in individual studies at high doses which caused parental toxicity. Further, weak effects on the offspring consisting of reduced pup weight and delayed preputial separation were seen at high dose levels and were associated with signs of paternal toxicity. Treatment-related effects in parent animals were similar to those seen in subchronic and chronic toxicity studies and occurred at comparable dose levels.

Developmental toxicity studies were performed in rats and rabbits.
Glyphosate did not cause teratogenicity in any of the conducted studies. Adverse effects on the number of viable foetuses and the foetal weight were noted in rats and rabbits at higher dose levels also causing maternal toxicity. A reduced ossification and a higher incidence of skeletal and/or visceral anomalies at these dosages were also indicative of foetotoxicity. Overall, there is an inconsistent pattern of the most commonly occurring cardiac defects at maternally toxic doses without a clear dose effect. The overall ~~lowest~~ NOAEL for developmental effects was 300 mg/kg bw/day in rats (CA 5.6.2/003) and 175 mg/kg bw/day in rabbits ([redacted], 1991; CA 5.6.2/014 and CA 5.6.2/015).

CA 5.6.1 Generational studies

In the previous glyphosate evaluation (RAR, 2015) a number of multi-generation studies were reviewed. The available data are summarised below. In addition, results of the conducted one-generation studies are considered as supportive data for the current assessment. Relevant and reliable literature was also assessed to finally evaluate intrinsic properties of glyphosate on reproductive tissues and organs. A summary of the considered literature is shown in the below table.

§ The category describes the acceptability/reliability of the study within the AIR 5 submission. This category does not describe hazard classification.

Publications on reproductive toxicity

A literature search for the active substance glyphosate was performed in accordance to the provisions of the EFSA Guidance "Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) 1107/2009" and updated Appendix to this Guidance document. The following publications were found relevant and reliable for this section and the summaries are thus presented below and are part of the general discussion at the beginning of the section.

Table Error! Use the Home tab to apply Überschrift 2 to the text that you want to appear here.**.1-2: Publications on reproductive toxicity on glyphosate**

Annex Point	Study	Study type	Substance(s)	Results (given for glyphosate exposure only)	Applicant assessment
CA 5.6.1/015	Gorga *et al.*, 2020	*in vitro* effects on Sertoli cell cultures, 10-100 ppm	Glyphosate and Roundup Full II	Altered Sertoli cell junction barrier permeability and decreased testosterone-stimulated TER; redistribution of claudin11	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used was not sufficiently characterised, there was no positive control and most of the endpoints were tested at only 2 concentrations preventing any dose-response evaluations, with the highest concentration exceeding a physiologically relevant dose.
CA 5.6.1/016	Manservisi *et al.*, 2019	SD rat (13 weeks, dose range-finder OECD 443), drinking water, 1.75 mg/kg bw/day	Glyphosate (Purity: 99.5 %) and Roundup (Bioflow)	Offspring: increased anogenital distance at PND 4 in males; increase in plasma TSH concentration in males	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because of the limited number of animals used per dose level and only one dose level tested.
CA 5.6.1/017	Pham *et al.*, 2019	Swiss mouse (GD 0 p.c. PND 2), drinking water 0, 0.5, 5, 50 mg/kg bw/day	Glyphosate (Purity: 99.2 %) and Roundup 3 Plus	No adverse effects observed on male offspring and endocrine endpoints including testicular function	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the test conditions were not clearly described and the number of animals tested per dose level is too limited.
CA 5.6.1/018	Ren *et al.*, 2019	ICR Mouse (GD 0 up to PND 21) drinking water, 0.5%	Glyphosate (Purity: 99.2 %) and Roundup 3 Plus	Offspring: hepatic steatosis, increased serum and liver concentrations of lipids	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used is not sufficiently characterised, only one dose level was tested, there was large inter animal variability observed and too few animals per dose level were analysed.
CA 5.6.1/019	Zhang *et al.*, 2019	*in vitro* effects on mice oocyte cultures, 500 µM	Glyphosate (Purity: not reported)	Effects on oocyte development and apoptotic fate	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because of the poor characterisation of the

Table Error! Use the Home tab to apply Überschrift 2 to the text that you want to appear here.**.1-2: Publications on reproductive toxicity on glyphosate**

Annex Point	Study	Study type	Substance(s)	Results (given for glyphosate exposure only)	Applicant assessment
					glyphosate tested, no cytotoxicity testing, the lack of a positive control and insufficient dose-response characterisation at biologically relevant doses.
CA 5.6.1/020	Johansson *et al.*, 2018	SD rat (14 days), gavage, 0, 2.5, 25 mg/kg bw/day	Glyphosate (Purity: ≥96 %) and in herbicide formulation (Glyfonova)	No effects observed on either of the various testicular parameters examined	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because only two dose levels were used to explore the dose-effect relationship for the endpoints assessed.
CA 5.6.1/021	Panzacchi *et al.*, 2018	SD rat (treatment from weaning to PND 73 or 125), drinking water, 1.75 mg/kg bw/day	Glyphosate (Purity: >99.5 %) and Roundup Bioflow	No effects on examined endpoints. Similar toxicity profile of pure glyphosate and reference formulation.	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because only one dose level for glyphosate and MON 52276 was considered, only 8 animals were used per dose and per sex and the method of analysis of glyphosate and AMPA in urine and its validation were not fully reported.
CA 5.6.1/022	Perego *et al.*, 2017	in vitro effects on bovine granulosa and theca cells, 0, 0.01, 0.03, 0.5, 1.7, 5.0 µg/mL	Glyphosate (Purity: >99.5 %)	Impaired granulosa cells proliferation and estradiol production at 5 µg/mL, but no effects at lower, physiologically relevant, concentrations	This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate tested was not sufficiently characterised, no positive controls were used and the tests were conducted with only one or 2 test concentrations of glyphosate.
CA 5.6.1/023	Dai *et al.*, 2016	SD rat (5 weeks), gavage, 0, 5, 50, 500 mg/kg bw/day	Glyphosate (Purity 90 %)	Reduced food consumption at 50 mg/kg bw/day, decreased weight of seminal vesicle gland, coagulating gland as well as the total sperm count at 500 mg/kg bw/day	This publication is considered relevant but reliable with restrictions because there are deviations from regulatory guidelines for reproductive toxicicity studies and the reproductive effects seen are not corroborated by the results from guideline studies at similar dose

Table Error! Use the Home tab to apply Überschrift 2 to the text that you want to appear here.**.1-2: Publications on reproductive toxicity on glyphosate**

					levels.
CA 5.6.1/024	Forgacs *et al.*, 2012	*in vitro*, murine Leydig cell culture, 1, 3, 10, 30, 100, 300, 600 µM	Glyphosate (Purity: not reported)	No effect on induction of testosterone production or alteration of rhCG induction of testosterone	This publication is considered relevant for glyphosate risk assessment but reliable with restrictions because the test substance was not characterised and the results of only one concentration level were reported.

GD gestational day
PND post-natal day

In the most recent two-generation study by [redacted]. (CA 5.6.1/001; CA 5.6.1/002 and CA 5.6.1/003) possible treatment-related effects on the parental and offspring generations were observed. Briefly, increased liver (F0 and F1 females) and kidney weights were observed in females of both generations at 15000 ppm. No similar findings were detected in males. No toxicological concern regarding the significantly increased liver weights is considered due to the absence of any histopathological changes in the liver. Further, at 15000 ppm a significant decrease in homogenisation resistant spermatids (HRS, cauda epididymis) was counted in F0 males (control: 400 million/gram; 15000 ppm: 309 million/gram**). No similar effects were seen at lower dose levels or at any dose levels in F1 males. In F1 male offspring preputial separation was delayed at 15000 ppm without any additional developmental retardation indicating a delay in male sexual maturation. Sperm changes and histopathological examinations did not reveal any changes in the testis or epididymes. Although, the later onset of preputial separation in male offspring at 15000 ppm had obviously no impact on reproductive performance in week 29, a treatment related effect on sexual maturation at parental toxic dose cannot be excluded. However, it is important to note that this finding occurred at the limit dose at which parental toxicity was also apparent. Based on the above mentioned effects, a NOAEL of 5000 ppm (ca. 351 mg/kg bw/day) is considered for parental, reproductive and offspring toxicity.

In the [redacted] (2000) (CA 5.6.1/004) study, fertility and reproductive performance was not adversely affected by treatment. No impact on sexual maturation was observed up to the highest dose level of 10000 ppm. A reduction in body weight of F1A pups was observed at the highest applied dose of 10000 ppm resulting in a subsequent reduction in body weight of the selected F1 parent males for the duration of the mating period. A NOAEL of 3000 ppm (equivalent to 322 and 459 mg/kg bw/day for males and females, respectively) was considered for the parental generations and offspring for both generations. A NOAEL of 10000 ppm is derived for reproductive toxicity.

In a further two-generation study performed by [redacted] (1997) (CA 5.6.1/005), no treatment-related signs of toxicity were noted in parental animals up to 6000 ppm. At 30000 ppm, treatment-related adverse effects were observed that consisted of defecation of loose stool in males and females, and lower body weights in males compared to control group males in both generations. Further, distension of the caecum and increased liver and kidney weights were evident at this dose level in males. Decreased prostrate weights were detected in F1 males at necropsy. Reproductive performance was not affected by the treatment in any dose group. Slightly lower gestation indices were observed in F1 females at 6000 and 30000 ppm which were considered unrelated to treatment, as shown by the results of the reciprocal crosses of F1 animals with untreated rats. Pups of both sexes of the F1 and F2 generation showed significantly decreased body weight

at 30000 ppm. Based on the results the NOAEL for parental and offspring toxicity was considered to be 6000 ppm (417 mg/kg bw/day). A NOAEL of 30000 ppm is considered for reproductive toxicity.

Supportive data indicating no hazard on reproduction are obtained by the two-generation study performed by [redacted] (1993) (CA 5.6.1/006). Parameters like general health, growth of parents, gestation/lactation period, body weight and food consumption, gross necropsy findings of pups and parents were unaffected by treatment up to the highest tested dose of 10000 ppm. Further, glyphosate did not affect mortality incidence, parturition performance, mean litter size, pup weight and male and female fertility index. Thus, the highest dose of 10000 ppm is considered to be the NOAEL for parental, reproductive and offspring toxicity.

In the study by [redacted] [redacted] (1992) (CA 5.6.1/007 and CA 5.6.1/008) no effects on reproduction (reproductive performance, fertility, parturition, lactation, sperm parameters and oestrus cycle) were noted up to the maximum dose of 10000 ppm. Oral administration of glyphosate to rats by dietary admixture at a maximum dose level of 10000 ppm for two successive generations resulted in minimal effects consisting of increased food and water consumption of F1 females and possibly reduced body weights of F1 males. Minimal histopathological changes on the salivary glands were observed in parental and offspring animals at 10000 ppm and to a lower extent at 3000 ppm. This observation was also noted in other repeated-dose studies with glyphosate but is considered an adaptive response to high dietary doses of glyphosate, which is a strong organic acid, and can therefore cause irritation of the oral cavity leading to increased salivary excretion. Thus, the parental reproductive and offspring NOAELs are considered to be 10000 ppm, corresponding to 668 and 752 mg/kg bw/day in males and females, respectively.

In the respective one-generation dose-range finding study performed by [redacted] [redacted] (1991) (CA 5.6.1/009) 3000, 10000 and 30000 ppm were applied from day 3 of pregnancy through to termination of the study. No effects on reproductive parameters were noted at any dose. Maternal toxicity was dose-dependently evident starting already at the lowest dose tested determined by slightly lower body weight gain, macroscopic salivary gland changes and macroscopic gastro-intestinal changes, minimal granular basophilic cytoplasm of acinar cells with minimal hypertrophy of acinar cells. Findings in the offspring were observed at 30000 ppm and included a reduction in litter and mean pup weight, loose faeces, reduced food intake and food conversion ratio and, in males only, a slight continuation of the reduced weight gain evident from birth to weaning was observed in the offspring. Findings at post mortem examination included macroscopic changes to the salivary gland and gastro-intestinal disturbances in males and females.

The two-generation study by [redacted] (1990) (CA 5.6.1/010) confirmed that glyphosate does not affect reproduction capacity in rats exposed over two consecutive generations to 30000 ppm. Maternal toxicity was evident in the high dose group at 30000 ppm indicated by soft stool and reduced body weights. At the same dose level, pups showed decreased body weights (about 10 %) when compared to controls. In the 10000 ppm dose group, decreased pup body weights were observed, but the effect was less pronounced and occurred not in both sexes of all generations. The NOAEL for reproductive toxicity was considered to be 30000 ppm. The NOAEL for parental and developmental toxicity was considered to be 10000 ppm.

Two studies are available from [redacted] (1988) (CA 5.6.1/011 and CA 5.6.1/012) including a three-generation and a one-generation study in rats. Both studies are considered as supportive data due to the very low dietary concentrations applied. In both studies, reproduction was not affected up to the maximum concentration of 300 ppm (calculated to be similar to 15 mg/kg bw/day) or 10 mg/kg bw/day in the three-generation and one-generation study, respectively. Likewise, no effects indicating parental, offspring or developmental toxicity were observed.

Based on the submitted reproductive toxicity studies, an overall parental NOAEL is 700 mg/kg bw/day, well below the lowest parental LOAEL of 1000 mg/kg bw/day ([redacted] 1997, CA 5.6.1/005; [redacted], 2000, CA 5.6.1/004; [redacted] [redacted] [redacted], 2007, CA 5.6.1/001 – CA 5.6.1/003; Figure 5.6.1-1), which is somewhat consistent with the subchronic studies. Parental toxicity was observed in those, independent studies mainly indicated by gastro-intestinal disturbances (soft stool, distension of caecum), reduced body weight and

organ weight changes. Furthermore, increased food and water consumption and an increased incidence of hypertrophy and basophilic staining of the parotid (males and females) and submaxillary (females) salivary glands were observed. The minimal histological alterations in the salivary gland are considered as an adaptive response to high dietary doses of glyphosate, which is a strong organic acid, due to local irritation of the oral cavity leading to increased and prolonged salivary excretion. The lowest NOAEL for parental toxicity was defined as 3000 ppm (322 and 459 mg/kg bw/day in males and females, respectively ([redacted], 2000, CA 5.6.1/004).

In offspring, body weight gain was reduced at parentally toxic dose levels and, in one study, preputial separation was delayed, and considered secondary to parental toxicity ([redacted], 2007, CA 5.6.1/001 – CA 5.6.1/003). The overall NOAEL/LOAEL values were the same as for parental toxicity, 700 mg/kg bw/day and 1000 mg/kg bw/day respectively (Figure 5.6.1-2).

Regarding reproductive toxicity, equivocal effects on litter size was observed in one study ([redacted] 1990, CA 5.6.1/010) at the extremely high dose of 2000 mg/kg bw/day. In another study a significant decrease in homogenisation-resistant spermatid count in F0 males was observed at ca. 1000 mg/kg bw/day, and considered secondary to general toxicity ([redacted], 2007, CA 5.6.1/001 – CA 5.6.1/003). The overall NOAEL for reproductive toxicity was 700 mg/kg bw/day (Figure 5.6.1-3).

Published studies rated as reliable and relevant for hazard assessment of reproductive toxicity include *in vitro* and *in vivo* investigations. In some studies, highly specific endpoints on cellular level including molecular investigations on protein and RNA level were investigated. An interpretation of those molecular and cell type-specific observations in regard to reproductive toxicity in intact organisms is challenging. The biological significance of effects observed in these specific studies in intact organs within their physiological environment is not yet validated and hence, concluding on reproductive toxicity is currently not considered as appropriate.

In the following, the most relevant reported findings after glyphosate treatment are discussed briefly.

In some studies the effects of glyphosate and Round-up formulations have been investigated. In the following, the focus is on effects after glyphosate treatment. The results obtained after treatment with the Round-up formulations are described in the respective summaries (please refer to CA 5.6.1/015 - CA 5.6.1/024).

Effects on the male reproductive system were investigated in two *in vitro* and four *in vivo* studies following different treatment protocols. Briefly, *in vitro* exposure of Sertolli cells to glyphosate was reported to alter Sertolli cell junction barrier permeability and to decrease testosterone-stimulated TER. Further, a redistribution of claudin11 was observed ([redacted] (2020) (CA 5.6.1/015). No effects on the induction of testosterone production or alteration of recombinant human CG induction of testosterone was reported in Leydig cells up to 600 µM (Forgacs (2012) (CA 5.6.1/024).

Under *in vivo* conditions, decreased weight of seminal vesicle gland, coagulating gland as well as the total sperm count was reported in rats after subacute exposure to 500 mg/kg bw glyphosate/day (Dai *et al.* (2016) (CA 5.6.1/023). Further, sperm-depleted seminiferous tubuli were reported in mice exposed to 5 mg glyphosate/kg bw/day (Pham *et al.* (2019) (CA 5.6.1/017). No similar effect was observed in the same study in mice sacrificed at later time points. For both test groups, exposure to glyphosate was stopped at PND 20. The biological significance of the observed findings on seminiferous tubules depletion remains highly questionable as the overall quality of the obtained data is not sufficiently conclusive to indicate test substance-specific adverse effects on testicular function and development especially as the effect was only seen in the mid-dose group.

No effects on testes have been observed after *in vivo* exposure up to 25 mg/kg bw/day over 14 weeks in a NTP study (Johansson *et al.* (2018) (CA 5.6.1/020). Likewise, sperm parameters (number of mature spermatids in the testis, daily sperm production, number and sperm transit time through caput/corpus and

cauda epididymis and morphology) remained to be unaffected by glyphosate exposure at the US ADI of 1.75 mg/kg bw/day for over 13 weeks (Manservisi *et al.* (2019) (CA 5.6.1/016).

Overall, the published data might suggest that the male reproduction system was adversely affected by glyphosate exposure leading to reduced sperm counts at doses of at least 500 mg/kg bw/day. Likewise, a significant decrease in homogenisation-resistant spermatid count in F0 males was observed at ca. 1000 mg/kg bw/day in the regulatory study performed by [redacted] (2007), and considered secondary to overt toxicity (CA 5.6.1/001 – 003). Based on the latter study, a NOAEL of 351 mg/kg bw/day was derived for reproductive toxicity, which covers the effects described in the literature by Dai *et al.* (2016) (CA 5.6.1/023).

Effects on maturation of oocytes was investigated in two studies under *in vitro* conditions. Zhang *et al.* (2019) (CA 5.6.1/019) reported that 500 µM glyphosate treatment negatively affected development of mouse oocytes as indicated by reduced rates of germinal vesicle breakdown and first polar body extrusion. Further, molecular analysis indicated increased reactive oxygen species and an influence of glyphosate on DNA stability and intracellular signaling pathways relevant for apoptosis. As only one concentration was applied in this study, no distinction between spontaneous or treatment-related causes is possible and hence, biological significance of these observations is rather difficult to evaluate. Further, Perego *et al.* (2017) (CA 5.6.1/022) investigated ovarian function in bovine granulosa and theca cells after glyphosate stimulation. A slight, non-dose-related alteration in bovine granulosa cell proliferation and estradiol production was observed. Due to the isolated occurrence of the observed effects without any dose-response relationship, the biological significance of those findings is rather limited and not considered to indicate hazardous properties of glyphosate on overall ovarian function.

In general, effects observed on isolated oocytes which have been taken out from their physiological, cellular environment (which can be considered as protective environment towards e.g. xenobiotics and also physical stressors), can only be considered to be of limited *in vivo*-relevance. Thus, when interpreting the reported findings on isolated oocytes together with the results of the performed multi-generation studies, in which fertility in females was unaffected by glyphosate treatment in any study, the effects hypothesised in the publications are not considered to conclusively indicate a hazard to female fertility.

In addition to these rather specific investigations, three further *in vivo* studies are published, in which reproductive and developmental toxicity were investigated in a manner which can be considered as similar to OECD guideline studies with limitations and deviations (For details please refer to CA 5.6.1/016; CA 5.6.1/018 and CA 5.6.1/022). Manservisi *et al.* (2019) (CA 5.6.1/016) performed a pilot study for an extended-one generation study (OECD 443). Reproductive parameters remained to be unaffected by glyphosate exposure at 1.75 mg/kg bw/day (representing the US ADI).

Overall, a delay in male sexual development indicated by increased anogenital distance observed on PND 4 and an increased TSH level in plasma was reported in male rats. Due to relevant methodological limitations, including the low number of test animals and timing of blood sample collection, interpretation of the reported findings should be considered with high uncertainty. However, a significant delay in sexual maturation in male offspring (F1) indicated by delayed preputial separation (occurring after 45.9 days in the mean versus 43.0 days in the control group) was also observed in the regulatory study performed by [redacted] (2007) (CA 5.6.1/001 – 003), which became apparent at the top dose level of 15000 ppm (higher than 1000 mg/kg bw/day), and considered secondary to parental toxicity. Thus, following a weight-of-evidence approach a negative effect on male sexual development cannot be fully excluded.

No clear evidence for glyphosate-induced foetal or developmental toxicity was found in the study reported by Ren *et al.* (2019) (CA 5.6.1/018). Hepatic steatosis and increased serum and liver concentrations of lipids were announced by the authors to occur in the offspring. Although the authors concluded that there were treatment related effects on foetal and offspring body weight after treatment with 0.5 % glyphosate solution (w/v, 0.5 g/100 mL) during pregnancy, there is no evidence from this study to suggest that glyphosate exposure has had any impact on foetal or pup development (Please refer to CA 5.6.1/018 for

further discussion).

Further, pregnancy and early life stages were reported to be unaffected by glyphosate exposure after subchronic exposure to 1.75 mg/kg bw/day (Panzacchi *et al.* (2018) (CA 5.6.1/021).

Overall, a comprehensive review of recently published literature did not provide conclusive evidence that glyphosate exposure negatively affects reproduction.

Figure 5.6.1-01. Rat multigenerational study parental NOAEL and LOAEL values, showing "overall" parental NOAEL of 700 mg/kg bw/day [1. [redacted] (2007) (CA 5.6.1/001 – 003); 2. [redacted] (2000) (CA 5.6.1/004); 3. [redacted] (1997) (CA 5.6.1/005); 4. [redacted] (1993) (CA 5.6.1/006); 5. [redacted] (1992) (CA 5.6.1/007 – 008); 6. [redacted] (1990) (CA 5.6.1/010); 7. Figure 5.6.1-02. Rat multigenerational study offspring NOAEL and LOAEL values, showing "overall" offspring NOAEL of 700 mg/kg bw/day [1. [redacted] (2007) (CA 5.6.1/001 – 003); 2. [redacted] (2000) (CA 5.6.1/004); 3. [redacted] (1997) (CA 5.6.1/005); 4. [redacted] (1993) (CA 5.6.1/006); 5. [redacted] (1992) (CA 5.6.1/007 – 008); 6. [redacted] (1990) (CA 5.6.1/010); 7. [redacted] (1988) (CA 5.6.1/0011); 8. [redacted] (1988) (CA 5.6.1/0012); 9. [redacted] (1981 (CA 5.6.1/0014))]

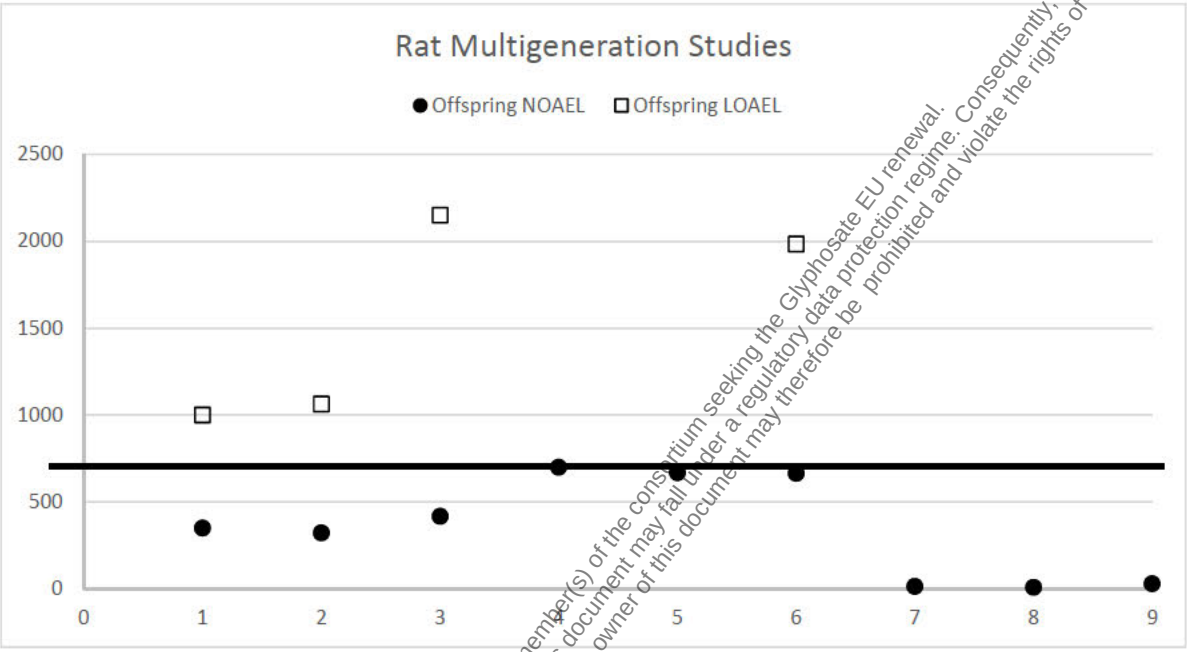

Figure 5.6.1-03. Rat multigenerational study reproductive NOAEL and LOAEL values, showing overall reproductive NOAEL of 700 mg/kg bw/day [1. [redacted] (2007) (CA 5.6.1/001 - 003); 2. [redacted] (2000) (CA 5.6.1/004); 3. [redacted] (1997) (CA 5.6.1/005); 4. [redacted] (1993) (CA 5.6.1/006); 5. [redacted] (1992) (CA 5.6.1/007 - 008); 6. [redacted] (1990) (CA 5.6.1/0010); 7. [redacted] (1988) (CA 5.6.1/0011); 8. [redacted] (1988) (CA 5.6.1/0012); 9. [redacted] (1981) (CA 5.6.1/0014)]

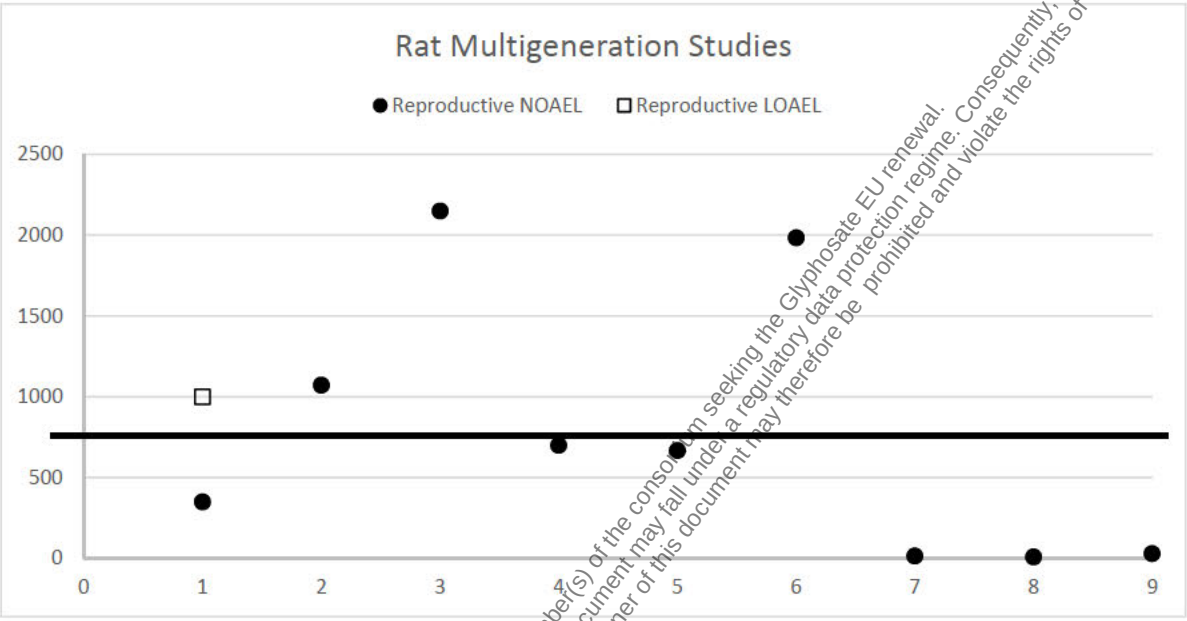

Taking into account all available generational studies on glyphosate, the overall multigenerational study NOAEL in rats for parental, offspring and reproductive toxicities is 700 mg/kg bw/day.

2. Full summary

Glyphosate technical was administered by dietary admixture to three groups of 28 male and female F0 generation Sprague-Dawley rats each, at dietary concentrations of 1500, 5000 and 15000 ppm (equivalent to a mean achieved dosage of 104, 351 and 1063 mg/kg bw/day for males and 162, 530 and 1634 mg/kg

bw/day for females respectively). A further group of 28 male and 28 female F0 animals was exposed to basal laboratory diet to serve as a control.

Clinical signs, body weight development, food and water consumption were monitored during the study. After 10 weeks of treatment, pairing of animals within each dose group was undertaken on a 1:1 basis. At weaning of offspring from the F0 mating phase, groups of 24 male and 24 female offspring from each dose group were selected to form the F1 generation. The remaining surviving F0 females and unselected offspring were terminated at Day 21 post partum, followed by the termination of all F0 male dose groups. The offspring selected for the F1 generation were dosed for at least 10 weeks and then paired within each dose group to produce the F2 litters. At weaning of the F2 litters all surviving adults and their offspring were killed, followed by the termination of all F1 male dose groups.

Oestrous cycle assessment was performed daily for three weeks prior to mating for both the F0 and F1 generations. Observations for positive evidence of mating were recorded together with the start and completion of parturition. During the maturation phase of the F1 generation offspring, males and females were evaluated for sexual maturation. The ano-genital distance was recorded for all F2 generation offspring on Day 1 post partum. During the lactation phases daily clinical observations were performed on all surviving offspring, together with litter size. Litter weight, individual offspring weights and landmark developmental signs were also recorded on specific days post partum.

All animals at termination were subjected to a gross necropsy examination and histopathological evaluation of selected tissues was performed.

The following treatment-related effects were observed:
During the end of the lactation phases, females showed less body weight loss when compared to controls for the F0 and F1 generations. There was no adverse effect on body weight change for males throughout the treatment period, or for females during the pre-pairing and gestation phases of the study.
An increase in liver weights was noted for females treated with 15000 ppm from both generations. No such effect was noted for males treated with 15000 ppm or for animals of either sex treated with 5000 or 1500 ppm. However, this finding was considered as an adaptive response to treatment and not as an adverse health effect.

There were no treatment-related histopathological changes for F0 generation animals. Treatment-related changes in the F1 generation were confined to the presence of lower incidences and severities of cortical vacuolation of the adrenal glands for treated males when compared to controls.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White crystalline solid
Lot/Batch #:	H05H016A
Purity:	95.7 % (w/w)
Stability of test compound:	Not reported
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Sprague-Dawley Crl:CD (SD) IGS BR
Source:	[redacted]

Age:	Approximately 8 weeks
Sex:	Males and females
Weight at dosing:	Males: 138 – 257 g; females: 140 – 195 g
Acclimation period:	At least 14 days
Diet/Food:	Rodent PMI 5002 (certified) diet (BCM IPS Limited, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Initially in groups of up to four in polypropylene cages with stainless steel grid floors and tops, suspended over polypropylene trays lined with absorbent paper. During mating animals were house one male : one female. Mated females were housed individually during gestation and lactation in polypropylene cages with solid floors and stainless steel lids, furnished with softwood flakes.
Environmental conditions:	Temperature: 21 ± 2 °C Humidity: 55 ± 15 % Air changes: at least 15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates
2005-11-18 to 2006-11-06

Animal assignment and treatment
In a two-generation reproduction study groups of 28 Sprague-Dawley rats per sex of the F0 generation received daily dietary doses of 0, 1500, 5000 and 15000 ppm (equivalent to mean achieved dose levels of 0, 104, 351 and 1063 mg/kg bw/day for males, and 0, 162, 530 and 1634 mg/kg bw/day for females) glyphosate technical in diet. The dose levels were chosen based on results of a previously conducted study and aimed to achieve the maximum regulatory limit of 1000 mg/kg bw/day. After 10 weeks of treatment pairing of animals within each dose group was undertaken on a one male: one female basis, to produce the F1 litters. At weaning of offspring from the F0 mating phase, groups of twenty-four male and twenty-four female offspring from each dose group were selected to form the F1 generation. The remaining surviving F0 females and unselected offspring were terminated at Day 21 post partum, followed by the termination of all F0 male dose groups. The offspring selected for the F1 generation were dosed for at least 10 weeks and then paired within each dose group to produce the F2 litters. At weaning of the F2 litters all surviving adults and their offspring were killed, followed by the termination of all F1 male dose groups.

Diet preparation and analyses
For preparation of diet mixtures a known amount of the test substance was mixed with a small amount of basal diet at a constant speed for 19 minutes in a Hobart QE200 mixer. This pre-mix was then added to larger amount of basal diet and blended for further 30 minutes in a Hobart H800 mixer.
The stability and homogeneity of the test material in diet were determined. Dietary admixtures were analysed for achieved concentration weekly for the first four weeks of the study and monthly thereafter.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made once daily.

Body weight
Individual body weights were recorded for F0 males on day 1 (prior to treatment) and at weekly intervals for F0 and F1 males until termination. F0 and F1 females were weighed daily until mating was evident.

Body weights for females showing evidence of mating were recorded on days 0, 7, 14 and 21 post coitum. Females with live litters were weighed on days 1, 4, 7, 14 and 21 post partum.

Food consumption and compound intake
During the maturation period, weekly food consumption was recorded for each cage of adults. For females showing evidence of mating, food consumption was recorded for the periods covering days 0 - 7, 7 - 14 and 14 – 21 post coitum. For females with live litters, food consumption was recorded for the period covering days 1 - 4, 4 - 7, 7 - 14, 14 - 21 post partum.
Food conversion efficiency (the ratio of body weight change / dietary intake) was calculated retrospectively for males for both the pre-mating and post-mating phases of the study. For females, food conversion efficiency was only calculated for the pre-mating phases of the study. Due to offspring growth, milk production and weaning, food efficiency could not be accurately calculated for the gestation and lactation phases of the study.

Water consumption
Water intake was observed daily by visual inspection of water bottles for any overt change.

Reproduction parameters
Oestrus cycle
Prior to pairing of females for the F0 and F1 mating phases, a vaginal smear was taken daily for twenty-one days and examined microscopically to determine the stage of oestrous.

Pregnancy and parturition
Pregnant females were observed at approximately 0830, 1230 and 1630 hours daily, and at approximately 0830 and 1230 hours on weekends and public holidays. In addition, the females were observed around the period of expected parturition. The date of mating, date and time of start and end of parturition and duration of gestation was recorded.

Litter data
The following litter data were recorded:
The number of offspring born, the number of offspring alive recorded daily and reported on day 1, 4, 7, 14, 21 post partum. On days 1, 4 and 21, the sex of individual offspring was recorded. The clinical condition of offspring during lactation, as well as individual offspring and total litter weights were recorded after birth on day 1, 4, 7, 14.

Physical and sexual development
All live offspring were observed for the detachment and unfolding of pinna, incisor eruption and eyelid separation and assessed for reflexological response to stimuli by assessing surface righting reflex on day 1 post partum and air righting reflex on day 17 post partum. Pupillary reflex and auditory startle response were performed on day 21 post partum.

All selected F1 offspring were observed for sexual development and the body weight for each individual animal at the time of sexual maturation was recorded. In addition, the ano-genital distance was recorded for all F2 generation offspring on day 1 post partum.

Sacrifice and pathology
All surviving adult females and surviving offspring, except offspring selected to form the F1 generation, as well as surviving males were sacrificed on day 21 post partum.
All adult animals and offspring, including those dying during the study, were subjected to a full external and internal examination, and any macroscopic abnormalities were recorded. For females the uterine implantation sites were counted. In addition, the corpora lutea of all ovaries from pregnant females were counted at necropsy.

The following organs of F0 males and females from each dose group that were sacrificed at the end of the

study sampled, weighed and preserved, except for the thyroids, which were weight after fixation:
adrenals, brain, left cauda epididymis, epididymides, kidneys, liver, ovaries, prostrate, pituitary, seminal vesicles (with coagulating gland and fluids), spleen, testes, thymus, thyroid glands, and uterus (with cervix and oviducts).

The following organs from one male and one female offspring from the F0 and F1 pairings were weighed: brain, spleen, thymus, and uterus.

The following tissues were preserved from all F0 males and females from each dose group in 10 % buffered formalin, except for the right epididymis, right testis, which were fixed in Bouins fluid and 70 % IMS: adrenals, coagulating gland, right epididymis, ovaries, right testis, pituitary, prostrate, seminal vesicles, Uterus (with oviducts) and cervix, vagina and all gross lesions.

A detailed histopathological examination was performed on all sampled tissues from all F0 and F1 control and high-dose animals, and on animals that died or were killed *in extremis*.
During the histopathological examination there were indications of treatment-related changes in the adrenal glands for the F1 animals. Thus, the microscopic examination was subsequently extended to include similarly prepared sections of adrenals from the F1 animals from the 5000 and 1500 ppm dose groups.

Semen assessment
At necropsy of adult F0 and F1 males at least 200 individual sperms were evaluated for motility, motility characteristics, and morphology. In addition, samples of the testis and cauda epididymis of the control and high dose animals were homogenised and examined for homogenisation resistant spermatids.

Evaluation of the oocyte number
From ten control and ten high dose females of the F1 generation slides of the ovaries were prepared and analysed for visible oocytes. The identified oocytes were classified as small, medium or large follicles.

Statistics
Organ weight (absolute and relative to terminal body weight), weekly body weight gain, litter weights and offspring body weights were assessed for dose response relationships by linear regression analysis, followed by one way analysis of variance (ANOVA) incorporating Levene's test for homogeneity of variance. Where variances were shown to be homogenous, pair wise comparisons were conducted using Dunnett's test. Where Levene's test showed unequal variances the data were analysed using non-parametric methods: Kruskal-Wallis ANOVA and Mann-Whitney 'U' test.
The non-parametric methods were also used to analyse implantation loss, offspring sex ratio and developmental landmarks and reflexological responses.
Probability values (p) are presented as follows:
$p<0.001$ ***
$p<0.01$ **
$p<0.05$ *
$p\geq0.05$ (not significant)

Histopathology data were analysed using the following methods to determine significant differences between control and treatment groups for the individual sexes:
1. Chi-squared analysis for differences in the incidence of lesions occurring with an overall frequency of one or greater.
2. Kruskal-Wallis one-way non-parametric analysis of variance for the comparison of severity grades for the more frequently observed graded conditions.
Probability values (p) were calculated as follows:
$p<0.001$ +++ --- ***
$p<0.01$ ++ -- **
$p<0.05$ + - *
$p<0.1$ (+) (-) (*)

p≥0.1 N.S. (not significant)
(+)-signs indicate positive differences from the control group, and (-)-signs indicate negative differences.
* refer to overall differences between group variation which is non-directional.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS

Stability analyses indicated that the dose preparations at nominal concentrations of 1500, 5000 and 15000 ppm were stable for at least six weeks at ambient temperature.
Analyses for homogeneity at the start of treatment indicated that the dose preparations were homogeneous.
Analyses for achieved concentration performed on ten separate occasions demonstrated that the prepared dietary admixture concentrations given to the animals were in the range of 83 to 102 % of the nominal concentration.

B. TEST COMPOUND INTAKE

The group mean achieved dosages are summarised in the table below.

Table 5.6.1-03-: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Group mean achieved dose levels

Group	Dietary concentration (ppm)	Estimated dose level (mg/kg bw/day)	Mean achieved dose level (mg/kg bw/day)			
			Males	Females		
				Maturation	Gestation	Lactation
Control	0	0	0	0	0	0
Low	1500	75	104	126	108	252
Intermediate	5000	250	351	423	358	808
High	15000	750	1063	1273	1109	2520

C. MORTALITY

There were no test substance-related mortalities.

Four unscheduled deaths occurred during the study. In the F0 generation one male of the low dose group and one female of the mid dose group was killed for humane reasons on days 87 and 103, respectively. The male exhibited a mass of about 3 x 4 cm on the lower jaw. The female was in extremis following a suspected prolonged parturition. One high dose female was found dead on day 97 possibly due to complications during parturition.
In the F1 generation one control female was killed on day 99 following severe clinical signs (pallor of the extremities, lethargy, pilo-erection, hunched posture and staining around the ano-genital region); however the aetiology of the signs was not established.

D. CLINICAL OBSERVATIONS

No treatment-related clinical signs of toxicity were noted. Clinical signs observed in control and treated animals of the F0 and F1 generation are summarised in the tables below. These signs were considered unrelated to the test substance, since they were either commonly seen in laboratory rats, or caused by physical injury, or occurred in control and treated rats.

Table 5.6.1-4: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Observed clinical signs in F0 generation

Clinical sign	Number of rats affected in dose group*							
	Control (0 ppm)		Low (1500 ppm)		Mid (5000 ppm)		High (15000 ppm)

E. BODY WEIGHT

No adverse effect of body weight change was evident for treated animals in comparison to controls throughout the treatment period for both the F0 and F1 generations except for post-partum females treated

with 15000 ppm. During the final week of lactation, both the F0 and F1 generations showed statistically significant less body weight loss in comparison to controls (p < 0.001 and p < 0.01 respectively).

Table 5.6.1-6-: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Body weight changes during lactation (group mean values)

Dietary concentration (ppm)	No. of animals		Body weight Change (g) at day 4	7	14	21

F. WATER CONSUMPTION

Daily visual inspection of water bottles showed no overt intergroup differences in water intake for treated males and females from the F0 or F1 generations, when compared to their concurrent controls.

G. REPRODUCTIVE PARAMETERS

Oestrus cycle

There were no toxicologically-significant effects on female oestrous cycles.

Mating Performance, Fertility and Gestation

There were no treatment-related effects on mating performance, fertility and gestation length for both F0 and F1 generation animals.

Table 5.6.1-7a: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Mating, fertility and gestation parameters (F0)

H. LITTER DATA

Size and Viability
No overt differences in litter size and viability were detected. The mean numbers of corpora lutea and subsequent number of implantations did not indicate any adverse effect of dietary exposure and pre and post implantation loss for treated animals were essentially similar to controls. There were no toxicologically significant differences in sex ratio for both F0 - F1 and F1 - F2 litters.

Growth and Development
No adverse effects on mean offspring body weights, body weight change or development were detected for male and female offspring in comparison to their controls. Litter data (from F0-F1 and F1-F2): litter size, offspring survival indices, developmental maturation are tabulated in tables below.

Surface righting reflex was unaffected and all offspring displayed normal auditory and visual responses. The mid-air righting for F2 litters in the low-, mid- and high dose group were significantly reduced compared to the control group in a non-dose responsive manner, but was not observed in the F0-F1 offspring, this finding is considered to represent normal biological variation and was not considered to be test substance related. Physical maturation of the selected rats, as assessed by the age and body weight at completion of pinna unfolding, incisor eruption and eye opening was unaffected by the treatment. In F1 male offspring, sexual maturation (preputial separation) was delayed at 15000 ppm without any additional developmental retardation, hence a higher mean body weight was noted at attainment, see table below. No such effects were evident for females and there were no differences in mating performance, sperm changes and histopathological examinations did not reveal any changes in the testis or epididymis. In isolation, this finding was considered to be unrelated to treatment.

Table 5.6.1-8a: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Litter size – F0-F1

Clinical signs
No clinical signs of toxicity were observed for offspring from treated animals.

I. PATHOLOGY
Necropsy
There were no toxicologically significant macroscopic abnormalities detected in the F0 and F1 animals, nor in the offspring.

Organ weights
F0 females treated with 15000 ppm displayed statistically significant increases in liver weights, both absolute and relative to terminal body weight ($p<0.001$). An increase in liver weights was also noted for F1 females treated with 15000 ppm (absolute: $p<0.05$, relative: $p<0.01$). In the absence of any histopathological changes in the liver, and as increased liver weights without histopathological changes were also noted in another repeated dose toxicity study this finding is considered as an adaptive response rather than an adverse effect. Furthermore, F0 females treated with 15000 ppm displayed an increase in kidney weights, both absolute ($p<0.001$) and relative to terminal body weight ($p<0.01$) (see Table 5.6.1-9). No such observations were detected for males treated with 15000 ppm from either generation.

Table 5.6.1-10: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Liver and kidney weights (relative and absolute) of females (group mean values)

There were no toxicologically significant intergroup differences detected for the brain, spleen or thymus for offspring of either sex from either generation. Furthermore, there were no differences in uterus weights for treated females from either generation when compared to controls.

Sperm assessment

There were no toxicologically significant effects on the concentration, motility or morphology of samples of sperm from treated F0 and F1 generation males when compared to their controls. Furthermore, no abnormal sperm were detected in the control and treated males from either generation.

There were no toxicologically significant differences in homogenisation resistant spermatid counts for males treated with 15000 ppm from either the F0 or the F1 generation. The number of homogenisation resistant spermatid present in the cauda epididymis for F0 males treated at 15000 ppm were significantly lower than the controls (309 million/g vs. 400 million/g in the control). However, the statistical significance achieved was minimal (p<0.05). No difference in homogenisation resistant spermatid counts was in the testis or in F1 males (testis and cauda epididymides). In isolation, the reduction noted in F0 males was considered to have arisen incidentally.

Oocyte assessment
There were no toxicologically significant differences in follicle numbers for F1 females treated with 15000 ppm when compared to controls.

Histopathology
No treatment-related changes were detected in the F0 generation animals.

In the F1 generation cortical vacuolation of the adrenal glands was observed with a lower incidence and with generally lower grades of severity among males treated with 15000 ppm ($p < 0.05$), 5000 ppm ($p < 0.05 - 0.01$), and 1500 ppm ($p < 0.1 - 0.05$) when compared to controls. The group distribution of incidence and of severity grades may also suggest a consequence of treatment. However, the absence of a dose-related response, may suggest that a higher than normal background incidence of the condition among control male rats may have contributed to the effect on this occasion (Table 5.6.1-11).

Table 5.6.1-12: Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 2007): Incidence of adrenal cortical vacuolation in males at terminal kill

	Historical control data	Dietary concentration (ppm) 0		1500		5000		15000

Minimal	57	6	10	--	6	--	6	8	7
Slight	23	2	7	--	4	--	2	4	2
Moderate	1	0	0	--	0	--	0	0	1
% present	34.6	28.6	71	--	24	--	33	42.9	42

* significantly different from control group $p<0.1 – p<0.05$
** significantly different from control group $p<0.01 – p<0.05$
*** significantly different from control group $p<0.05$

All remaining morphological changes were those commonly observed in laboratory maintained rats of the age and strain employed and, since there were no differences in incidence or severity between control and treatment groups, all were considered to be without toxicological significance.

III. CONCLUSIONS

The oral administration of glyphosate technical to rats by dietary admixture at a maximum dose level of 15000 ppm for two successive generations resulted in possible treatment-related changes at 15000 ppm. The effects however were considered not to represent an adverse health effect, therefore the NOAEL was considered to be 15000 ppm (equivalent to 1063 and 1634 mg/kg bw/day, for males and females, respectively) for adult toxicity for both the F0 and F1 generations.
The NOAEL for reproductive and developmental toxicity, for both generations and offspring was considered to be 15000 ppm.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this study at the highest dose level of 15000 ppm increased organ weights in liver (F0 and F1 females) and kidneys (F0 females) were observed. The study authors stated that there is no toxicological concern regarding the significantly increased liver weights due to the absence of any histopathological changes in the liver. In fact, in the present study no evidence for histopathological examination of the liver was given. At this high dose level a significant decrease in homogenisation-resistant spermatids (HRS, cauda epididymis) was counted in F0 males (control: 400 million/gram; 15000 ppm: 309 million/gram**). Furthermore, in F1 male offspring sexual maturation (preputial separation) was delayed at 15000 ppm without any additional developmental retardation (e.g. body weight). The authors of the study considered this finding in F1 males (45.9 days versus control 43.0 day) to be unrelated to treatment, because no effects on sexual maturation were evident for females and there were no differences in mating performance. Sperm changes and histopathological examinations did not reveal any changes in the testis or epididymes. Although, the later onset of preputial separation in male offspring at 15000 ppm had obviously no impact on reproductive performance in week 29, a treatment-related effect on sexual maturation at a parental-toxic dose cannot be fully excluded. Therfore, the NOAEL for parental, reproductive and offspring toxicity is considered to be 5000 ppm (approx. equivalent to 351 mg/kg bw/day).

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/004**
Report author	[redacted]
Report year	2000
Report title	Glyphosate acid: Multigeneration reproduction toxicity study in rats
Report No	[redacted]/P/6332
Document No	Not reported
Guidelines followed in study	OECD 416 (2001), Annex V 67/548/EEC, 9.ATP 87/302/EEC OJEC, L133, 47-50 (1988), US-EPA OPPTS 870.3800 (1998)
Deviations from current test guideline (OECD 416, 2001)	Anogenital distance not examined as no treatment-related differences in sex ratio and sexual maturation were observed; thyroid weight not recorded; pre-implantation loss was not determined; pup development investigations restricted to body weight, vaginal opening and preputial separation.
Previous evaluation	Yes, accepted in RAR (2015)

GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Glyphosate acid was administered by dietary admixture to three groups of 26 male and female F0 generation Alpk:APfSD rats each, at dietary concentrations of 1000, 3000 and 10000 ppm. A further group of 26 male and 26 female F0 animals was exposed to basal laboratory diet to serve as a control.

After 10 weeks, the animals were mated and allowed to rear the F1A litters to weaning. The regime was repeated with the F1 parents (26 per sex and dose) selected from the F1A litters to produce the F2A litters after a 10 week pre-mating period. The remaining surviving F0 females and unselected offspring were terminated at Day 29 post partum, followed by the termination of all F0 male dose groups. At weaning of the F2 litters all surviving adults and their offspring were killed, followed by the termination of all F1 male dose groups. Diets containing glyphosate acid were fed continuously throughout the study. Clinical signs, body weight development, food and water consumption were monitored during the study.

Oestrous cycle assessment was performed daily for three weeks prior to mating for both the F0 and F1 generations. Observations for positive evidence of mating were recorded together with the start and completion of parturition. During the maturation phase of the F1 generation offspring, males and females were evaluated for sexual maturation. During the lactation phases daily clinical observations were performed on all surviving offspring, together with litter size. Litter weight, individual offspring weights and landmark developmental signs were also recorded on specific days post partum.

All animals at termination were subjected to a gross necropsy examination and histopathological evaluation of selective tissues was performed if necessary.

The body weights of the F1A pups in the 10000 ppm group were lower in comparison with the control group from Day 2 to Day 29 post partum although a similar effect was not observed for the F2A pups. In line with this, compound-related reductions in body weight and food consumption were evident only in F1 males given 10000 ppm. No further treatment related effects were observed.

I. MATERIALS AND METHODS

A. Materials

Test Material:

Identification:	Glyphosate acid, technical
Description:	White solid
Lot/Batch #:	Y04707/082
Purity:	97.6 % (w/w)
Stability of test compound:	At least 10 years at ambient temperature
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Alpk:APfSD (Wistar-derived)

Source:	[redacted]
Age:	At least 5 weeks old
Sex:	Males and females
Weight at dosing:	Males: approx. 160 g; females: approx. 140 g
Acclimation period:	At least 14 days
Diet/Food:	CT1 diet (Special Diet Services Ltd., Witham, Essex, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Rats were house in pairs (same sex) in multiple rat racks (with rats of the same group in adjacent cages). During mating animals were house one male : one female. Mated females were housed individually during gestation and lactation and provided with bedding material. After day 29 females separated from their litter were house in pairs until termination. Males were housed up to four per cage after being used for mating.
Environmental conditions:	Temperature: 22 ± 3° C Humidity: 50 ± 20 % Air changes: at least 15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: Not reported

Animal assignment and treatment:
In a two-generation reproduction study groups of 26 Alpk:APfSD rats per sex of the F0 generation received daily dietary doses of 0, 1000, 3000 and 10000 ppm glyphosate acid in diet. The dose levels were chosen based on results of a previously conducted 2-year dietary toxicity study.
After 10 weeks of treatment pairing of animals within each dose group was undertaken on a one male: one female basis, to produce the F1 litters. On day 29 post partum, groups of twenty-six male and twenty-six female offspring from each dose group of the F0 generation were selected to form the F1 generation. F0 males were terminated after the completion of littering and females were terminated on or soon after day 29 of lactation. Unselected offspring were terminated at day 29 post partum. The offspring selected for the F1 generation were dosed for at least 10 weeks and then paired within each dose group to produce the F2 litters. F2 litters were weaned off on day 29 post partum and terminated thereafter.

Diet preparation and analyses
For preparation of diet mixtures (60 kg) a known amount of the test substance was mixed with a small amount of basal diet in a mortar using a pestle. Further milled diet was added to give a pre-mix of 1000 g. Each pre-mix was grounded at a constant speed for 15 min with an automatic pestle and mortar. This pre-mix was then added to a larger amount of basal diet and blended for further 6 minutes in a Pharma Matrix Blender Model PMA 150S (TK Fielder). Control diet was treated in the same way but without addition of the test substance. The stability and homogeneity of the test material in diet were determined in the lowest and the highest dose. Dietary admixtures were analysed for achieved concentration at a 2 month interval.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made once daily.

Body weight
Individual body weights were recorded for F0 adults immediately prior to treatment and weekly thereafter

throughout the pre-mating period. F0 males were weighed weekly thereafter until termination. Successfully mated F0 females were weighed on day 1, 5, 8, 15 and 22 of gestation and on day 1, 5, 8, 15, 22 and 29 post partum. Initial body weights for the F1 adults were recorded at selection on day 29 post partum and weekly thereafter throughout the pre-mating period. F1 males were weighed weekly thereafter until termination. Successfully mated F1 females were weighed on day 1, 5, 8, 15 and 22 of gestation and on day 1, 5, 8, 15, 22 and 29 post partum. All rats were weighed at termination.

Food consumption and compound intake
Food consumption for each cage was recorded throughout the pre-mating period and calculated on a weekly basis. Food utilisation was calculated as the body weight gained by the rats in the cage per 100 g of food eaten. Food consumption was also recorded for females during gestation and lactation and calculated on a weekly basis.

Reproduction parameters
Oestrus cycle
Prior to pairing of females for the F0 and F1 mating phases, a vaginal smear was taken daily for twenty-one days and examined microscopically to determine the stage of oestrous. A vaginal smear was also taken and examined from all F0 and F1 females at termination.

Reproductive performance
The success of mating (production of viable litter) was established. Length of gestation was measured in days from the date of the positive smear to the date of birth. Pre-coital interval was measured as the number of days from the date of pairing to the date of the positive smear.

Litter data
The following litter data were recorded:
The number of offspring born and the number of offspring alive were counted within 24 h after parturition and thereafter on day 5, 8, 15, 22 and 29 post partum. The sex and the litter weight was also recorded at these times. Any clinical findings were recorded. Litters were examined for dead or moribund pups at least once daily.

Physical and sexual development
All selected F1 offspring were observed for sexual development and the body weight for each individual animal at the time of sexual maturation was recorded.

Sacrifice and pathology
All surviving adult females and surviving offspring, except offspring selected to form the F1 generation, were sacrificed on day 29 post partum. Males were sacrificed at completion of the littering. All adult animals and offspring, including those dying during the study, were subjected to a full external and internal examination, and any macroscopic abnormalities were recorded. For F0 and F1 females the uterine implantation sites were counted.

The following organs of F0 males and females from each dose group that were sacrificed at the end of the study were sampled, weighed and preserved:
adrenal gland, brain, left and right epididymides and caudae, kidneys, liver, ovaries, prostrate, pituitary, seminal vesicles (with coagulating gland and fluids), spleen, testes, uterus (with cervix and oviducts).
The following organs from one male and one female offspring from the F1 pairings were weighed: brain, spleen and thymus.

The following tissues were preserved from all F0 males and females from each dose group in 10 % buffered formalin, except for the left epididymis, left testis, which were fixed in Bouins fixative: adrenals, brain, coagulating gland, left epididymis, ovary, left testis, pituitary, prostrate, seminal vesicle, uterus (with oviducts) and cervix, vagina and all gross lesions.

Beside all pups killed in extremis (age 18-29 days) 3 male and 3 female per F2-litter were given a macroscopic examination at termination on day 29 post partum. One of the 3 pups/sex/litter was used for organ weight determination as described above. Following tissues were stored from these pups: brain, spleen, thymus, salivary gland. Abnormal tissue from all these pups were taken and fixed as described earlier.

The reproductive organs from animals suspected of reduced fertility were processed for histopathological examination.

Semen assessment
At necropsy of adult F0 and F1 males sperm were taken from the right distal cauda epididymis. At least 200 individual sperms were evaluated for motility, motility characteristics, and morphology. In addition, samples of the right testis of the control and high dose animals were homogenised and examined for homogenisation resistant spermatids.

Evaluation of the oocyte number
Primordial and small growing follicles were quantified in the left ovary of all F1 females from the control and high dose groups. Quantification was done using five 5 µm thick sections cut from the central third of each ovary and taken at least 100 µm apart and as evenly spaced as possible.

Statistics
One or a combination of the following statistical methods were applied for the evaluation of the measured parameters: analyses of variance (ANOVA), analyses of covariance, ANOVA followed by analyses of covariance, as well as ANOVA following the double arcsine transformation of Freeman and Tukey (1950), or ANOVA following a square root formation, or Fisher's Exact Test.

All analyses were carried out in SAS (1996). For Fisher's Exact Tests the proportion in each treated group was compared to the control group proportion. Analyses of variance and covariance, with the exception of pup organ weights, allowed for the replicate structure of the study design.

Least-squares means for each group were calculated using the LSMEAN Option in SAS PROC MIXED. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squares mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a Student's t-test, based on the error mean square in the analysis.
All statistical tests were two sided.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The chemical stability of glyphosate acid in the diet at nominal concentrations of 1,000 and 10,000 ppm was consistent for at least 6 weeks (at room temperature). Homogeneity of the test substance in the dietary mixture was satisfactory, percentage deviations from the overall mean were within 4%. The mean achieved concentrations of glyphosate acid in the preparations were within 9% of the nominal concentrations and the overall mean concentrations were within 3% of the nominal concentrations.

B. TEST COMPOUND INTAKE
The group mean achieved dosages are summarised in Table 5.6.1-13 below.

Table 5.6.1-13: Glyphosate acid: Multigeneration reproduction toxicity study in rats ([redacted], 2000): Group mean achieved dose levels F0 and F1 generation

Group	Dietary concentration (ppm)	Mean achieved dose level (mg/kg bw/day)				
		Males		Females		
		F0	F1	Maturation	Gestation	Lactation
Control	0	0	0	0	0	0
Low	1000	99.4	116.5	113.9	90.4	227.9
Intermediate	3000	292.6	351.8	346.8	277.9	752.4
High	10000	984.7	1161.0	1136.2	910.9	2424.8

C. MORTALITY

There were no test substance related mortalities.

Seven unscheduled deaths occurred during the study. In the F0 generation one control male was killed for humane reasons during week 9 because it was found to have a ruptured eyeball. In the low level dose group one female was killed for humane reasons during week 14 having failed to litter on time, dead foetuses were present in the uterus. In the intermediate level dose group one female was killed in week 14 on gestation day 23 due to difficulties with parturition. In the high-level dose group one female with an imperforate vagina and one male having a subcutaneous mass were killed in week 15 and 18, respectively. In the F1 generation two control animals were killed in extremis. One male due to an accidental injury in week 2 and one female in week 15 due to difficulties with parturition (one dead foetus present in uterus).

D. CLINICAL OBSERVATIONS

No treatment-related clinical signs of toxicity were noted.

During the pre-mating period, annular constrictions were visible on the tails of the F0 and F1 male and female rats. Almost all males and approximately half of the females, in all groups, were affected. Scaly tail was also observed in some of the animals. These findings were considered incidental to the administration of glyphosate acid in the diet. Other recorded changes in clinical condition were either isolated occurrences or of an incidence comparable with that of the control group.

These signs were considered unrelated to the test substance, since they were either commonly seen in laboratory rats, or caused by physical injury, or occurred in control and treated rats.

E. BODY WEIGHT

There was no effect of glyphosate acid on body weight adjusted for initial weight for the F0 rats, males and females, during the pre-mating period. For the F1 males given 10000 ppm, body weight was slightly lower at week 1, in comparison with the control group. Thereafter, body weights adjusted for initial weight remained lower than the controls for the duration of the pre-mating period and were statistically significant different from week 2 through to week 8 (see Table 5.6.1-14-). There was no effect of 10000 ppm on the body weight of the F1 females and no effect of 3000 or 1000 ppm on the body weight of the F1 males or the F1 females (see **Error! Reference source not found.**). There was no effect of glyphosate acid on body weight adjusted for initial weight for either the F0 or F1 rats during gestation or lactation.

Table 5.6.1-14-: Glyphosate acid: Multigeneration reproduction toxicity study in rats ([redacted], 2000): Body weight during the pre-mating period - F1 generation (group mean values, adjusted for initial weight)

F. FOOD CONSUMPTION, FOOD UTILISATION

There was no effect of glyphosate acid on food consumption for the F0 generation as well as all F1 females and F1 males of the low and intermediate level dose group during the pre-mating period. Only F1 males of the high-level dose group showed significantly lower food consumption throughout the pre-mating period. There was no effect of glyphosate acid on food utilisation for the F0 generation, all F1 females and F1 males of the low and intermediate dose group during the pre-mating period. Food utilisation was slightly higher for F1 males given 10000 ppm glyphosate acid, the difference from control being statistically significant for weeks 5-8 only. There was no effect of glyphosate acid on food consumption for either the F0 or F1 rats during gestation or lactation.

Table 5.6.1-15: Glyphosate acid: Multigeneration reproduction toxicity study in rats ([redacted], 2000): Food consumption and food utilisation during the pre-mating period - F1 generation males (group mean values)

G. REPRODUCTIVE PARAMETERS

Oestrus cycle

There were no consistent toxicologically-significant effects on female oestrous cycles.

Mating Performance, Fertility and Gestation

There were no treatment-related effects on pre-coital interval, mating performance, and gestation length for both F0 and F1 generation animals.

Table 5.6.1-16a: Glyphosate acid: Multigeneration reproduction toxicity study in rats ([redacted], 2000): Mating, fertility and gestation parameters (F0)

H. LITTER DATA

Size and Viability

No overt effects of glyphosate acid on pup survival or on litter size during lactation were detected.

In both generations the incidence of whole litter losses was low and similar across all groups. Glyphosate acid treatment did not affect the percentage of post-implantation loss. The proportion of F1A and F2A pups born live was slightly higher in the glyphosate acid groups than in the control group. There was no effect of glyphosate acid on litter size at birth or during the time of lactation for either the F1A or F2A pups. The proportion of litters with all pups surviving and the proportion of pups surviving during lactation were also unaffected by the treatment. An increased proportion of litters with all pups surviving noted for the F1A litters in the 10000 ppm group in comparison with the control group were not present for the F2A litters since the F2A controls showed an improvement over the F1A controls. Sex distribution within the litters was not altered by the administration of glyphosate acid. Individual pup body weights were recorded within 24 hours of births and on days 5, 8, 15, 22 and 29 post partum. As pups were not individually identified, the data were recorded by sex and litter.

Growth and Development

There was no effect of glyphosate acid on pup weight at birth for the F1A or F2A pups. Thereafter, the adjusted mean body weights of the F1A pups in the 10000 ppm group were lower in comparison with the control group. The differences from control were statistically significant for males from day 8 through to day 29, and for females from day 5 through to day 29 (see table below). A similar effect was neither observed for the F2A pups in the 10000 ppm group or for the F1A pups of the low and intermediate dose level groups. There was no effect of glyphosate acid on total litter weight of either generation. Also the day

of age when preputial separation or vaginal opening occurred in the F1 parents was unaffected by treatment.

Balano-preputial separation	Day of age	47.1 ± 2.3	46.6 ± 1.7	47.2 ± 1.6	48.0 ± 2.1

Clinical signs
No clinically observable signs of toxicity were noted for offspring from treated animals.

I. PATHOLOGY
Necropsy
No macroscopic findings that could be attributed to the treatment with glyphosate acid were observed in any animal of the F0 and F1 generation.

The incidence of unilateral pelvic dilatation was slightly higher (9/69) in F2A females in the 10,000 ppm group compared with the other groups. Unilateral pelvic dilatation is a very common spontaneous change in the Alpk:APfSD strain of rat. There was no increase in incidence in the F0 or F1 adults or in the F1A pups and, as an isolated observation, it is considered incidental to treatment with glyphosate acid.

Organ weights
The treatment of rats with glyphosate acid did not affect the weight of the adrenal glands, brain, right cauda epididymis, epididymides, kidney, liver, ovary, pituitary gland, prostate gland, spleen, seminal vesicles, testes or uterus. For the F0 males given 10000 ppm glyphosate acid, liver and kidney weights adjusted for body weight were statistically significantly greater than in the control group. Similar changes were not observed in the F1 males given 10000 ppm glyphosate acid. Absolute and relative values were comparable with the control group (see table below). The weight changes seen in the liver and kidney of the F0 males were therefore considered not to be treatment related. For the F0 males given 3000 or 10000 ppm glyphosate acid, brain weight adjusted for body weight was statistically significantly greater than in the control group. Absolute values were comparable with the control group. Similar changes were not observed in the F1 animals. The weight changes seen in the brain of the F0 males were therefore considered to be incidental to treatment.

There was no effect of glyphosate acid on brain, spleen or thymus weight.

For the F1A female pups in the 10000 ppm group absolute thymus weight was statistically significantly lower than in the control group. There was no effect of glyphosate acid on the thymus weight of the F2A pups. The observation in the F1A females is therefore considered incidental to treatment with glyphosate acid.

Sperm assessment
In F0 and F1 males no effect of glyphosate acid on the number of sperm, sperm motility parameters or sperm morphology was observed.

** significantly different from control group p<0.01

Oocyte assessment
There was no effect of 10000 ppm glyphosate acid on the number of primordial and small growing follicles in the left ovary of the F1 parent animals.

Histopathology
No treatment-related changes were detected in the F0 and F1 generations.

III. CONCLUSIONS

The oral administration of glyphosate acid to rats by dietary admixture at a maximum dose level of 10000 ppm for two successive generations of the Alpk:APfSD rat resulted in possible treatment-related changes at 10000 ppm, where a reduction in the body weight of the F1A pups in the 10000 ppm group with a subsequent reduction in body weight of the selected F1 parent males for the duration of the pre-mating period was observed. Therefore the 'No Observed Adverse Effect Level' (NOAEL) was considered to be 3000 ppm (equivalent to 322 and 459 mg/kg bw/day for males and females, respectively) for maternal and offspring for both the F0 and F1 generations.

3. Assessment and conclusion

Assessment and conclusion by applicant:
This study is considered valid in spite of some deviations from the most recent OECD 416 (2001). The oral administration of glyphosate acid to rats by dietary admixture at a maximum dose level of 10000 ppm for two successive generations of the Alpk:APfSD rat resulted in treatment-related changes at 10000 ppm, where a reduction in the body weight of the F1A pups in the 10000 ppm group with a subsequent reduction in body weight of the selected F1 parent males for the duration of the pre-mating period was observed. Therefore, the NOAEL was considered to be 3000 ppm (equivalent to 322 and 459 mg/kg bw/day for males and females, respectively) for maternal and offspring for both the F0 and F1 generations. The NOAEL for reproduction is considered to be 10000 ppm (equivalent to 1072 / 911 – 2425 mg/kg bw/day).

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.6.1/005
Report author	[redacted]

Report year	1997
Report title	HR-001: A two-generation reproduction study in rats
Report No	[redacted] 96-0031
Document No	Not reported
Guidelines followed in study	OECD 416 (1981), US-EPA FIFREA Guidelines Subdivision F (1984), Japan MAFF Guideline 59 NohSan No. 4200 (1985)
Deviations from current test guideline (OECD 416, 2001)	Number of animals used are not in line with the recommendation by the guideline; pup development investigations restricted to body weight; developmental landmarks (vaginal opening and preputial separation) not examined; anogenital distance was not determined; thyroid weight and histopathology were not determined; pre- and post-implantation loss were not reported; number of corpora lutea was not given; time to mating was not reported.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

To evaluate the potential effects of glyphosate on reproduction groups of 24 Sprague-Dawley rats per sex were fed diets containing test substance concentrations of 0, 1200, 6000 and 30000 ppm for two consecutive generations. Clinical signs, body weight development, food consumption were monitored during the study. Reproductive parameters (oestrus cycle, mating, fertility and gestation indices, sperm assessment) were also evaluated. Gross pathological examinations were performed on all animals. Organ weight determinations and histopathological examinations were also performed on designated animals. Litter data determined covered the total number of live and dead pups, the number of males and females, viability indices, body weights and clinical signs.

There were no treatment-related signs of toxicity noted in parental animals of the low- and mid-dose groups. At 30000 ppm treatment-related adverse effects consisted of defecation of loose stool in F0 and F1 males and females, and lower body weights in F0 and F1 males than in the respective control group males. Also in the high-dose group distension of the caecum and increased liver and kidney weights in F0 and F1 males and a decreased prostrate weight in F1 males were observed at necropsy.

Reproductive performance was not affected by the treatment in any dose group. The slightly lower gestation indices observed in F1 females of the mid- and high-dose group were considered unrelated to treatment, as shown by the results of the reciprocal crosses of F1 animals with untreated rats.

No treatment-related alterations were observed in offspring of the low- and mid-dose groups. In the high-dose group pups of both sexes of the F1 and F2 generation showed significant decreased body weight gains and a significant increase in the incidence of distension of the caecum.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical, Code: HR-001
Description:	White crystal
Lot/Batch #:	T-950308

Purity:	94.61 % (w/w)
Stability of test compound:	Not reported
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Sprague-Dawley; Crj:CD (SD)
Source:	[redacted]
Age:	5 weeks
Sex:	Males and females
Weight at dosing:	Males: 132 - 148 g; females: 112 - 126 g
Acclimation period:	7 days
Diet/Food:	Certified pulverised feed (MF Mash, Oriental Yeast Co., Ltd), *ad libitum*
Water:	Filtered, sterilised well water, *ad libitum*
Housing:	During acclimatisation in groups of five per sex in suspended wire-mesh stainless steel cages). During pre-mating, and mating periods animals were housed in groups o 3/sex/cage. During mating one male and one female were housed in aluminium cages with wire-mesh floors and fronts. Mated females were housed individually during gestation and lactation and provided with bedding material. After day 29 females separated from their litter were house in pairs until termination. Males were housed up to four per cage after being used for mating.
Environmental conditions:	Temperature: 22 ± 2 °C Humidity: 55 ± 10 % Air changes: 15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: 1996-04-16 - 1997-03-31

Animal assignment and treatment:
In a two-generation reproduction study groups of 24 Sprague-Dawley rats per sex of the F0 generation received daily dietary doses of 0, 1200, 6000 and 30000 ppm HR-001 in diet. The dose levels were chosen based on results of a preliminary reproductive study in Crj:CD (SD) rats. In the preliminary study, Crj : CD (SD) rats, 8/sex/group, were given diets containing glyphosate at dose levels of 0, 1000, 3000, 10000, or 30000 pprn during the 3–week-rearing and subsequent breeding periods. In the 30000 ppm group, treatrnent related adverse -effects on parental animals were evident, and the incidence of loose stool was significantly higher than that in the control grqup. Moreover, decreases in the body weights and food consumption were observed. The adverse effects on the body weights and food consumption were more prominent in males than in females, and statistically significant differences from controls were detected in the mean body weights of males on weeks 5, 6, and 8 of treatrnent. Necropsy of parental animals at termination of test substance treatment revealed distention of the cecum in males with a statistically significant increase in the incidence. In the 1000, 3000, and 10000 ppm groups, no treatment-related adverse effects on parental animals were detected. As for the reproductive performance of parental animals, no treatrnent-related adverse effects were detected in any treated groups. In offspring in the 30000 ppm group, treatment-related adverse effects were evident. The rnean body weights of both sexes on days 14 and 21 of lactation in this dose group were lower than those in the control group, and the differences on day 21 of lactation were

statistically significant. Necropsy of pups after weaning revealed distention of the cecum with a significantly increased incidence. In offspring in the 10000 ppm group, the following treatment-related adverse effects were also observed: a decrease in the body weights on day 21 of lactation and a low incidence of distention of the caecurn. In the 1000 and 3000 ppm group, no treatment-related abnormalities were detected in any pups. Based on these results, the dose level of 30000 ppm was selected for the high-dose level in the present study and 1200 and 6000 pprn for the low- and middle-dose levels, respectively.

After 10 weeks of treatment pairing of animals within each dose group was undertaken on a one male: one female basis, to produce the F1 litters. The day of proved copulation was designated day 0 of gestation. Copulated females were placed individually into breeding boxes with nestle material. The day of completed parturition was designated day 0 of lactation. On day 4 post partum, litter sizes were reduced to a maximum of 8 pups, preferable to 4 males and 4 females, and the remaining pups were culled. Weaning was done on day 21 of lactation and all F0 parental animals were sacrificed. Groups of 24 male and 24 female offspring from each dose group of the F0 generation were selected to form the F1 parents. Unselected offspring were sacrificed and subjected to a gross necropsy.

The offspring selected for the F1 generation were dosed for 10 weeks and then paired within each dose group to produce the F2 litters. F2 litters were weaned on day 21 of lactation and terminated together with F1 parental animals. F1 parental rats which failed to produce F2 offspring (10 males and 10 females with normal external genitalia and oestrus cycle) were mated with untreated rats of the same strain and sacrificed thereafter for fertility assessment (reproductive performance).

Diet preparation and analyses
Diets were prepared monthly during the pre-mating period, and biweekly during the breeding period. For each dose level a specified amount of the test substance was mixed with a small amount of basal diet in a mortar. This pre-mix was stirred into the remaining part of the diet. The diets were stored at about 4 °C in the dark. Analyses for homogeneity were done for each dose level of the first diet preparation. Analyses for achieved concentration were done for all prepared diets.

Clinical observations
A check for clinical signs of toxicity and mortality was made once daily on all F0 and F1 parental animals. A detailed physical examination was performed on males prior to treatment, and weekly during pre-mating and breeding periods and at necropsy. Females were examined prior to treatment, weekly during pre-mating periods and on gestation days 0, 7, 14 and 20, and on days 0, 7, 14 and 21 of lactation, and at necropsy.

Body weight
Individual body weights F0 and F1 males adults were determined prior to treatment, and weekly during pre-mating and breeding periods and at necropsy. F0 and F1 females were weighed prior to treatment, weekly during pre-mating periods and on gestation days 0, 7, 14 and 20, and on days 0, 7, 14 and 21 of lactation, and at necropsy.

Food consumption and compound intake
Food consumption for each cage was recorded and daily food consumption was calculated. Determination of food consumption was made on a weekly basis during the pre-mating period for males and females and during the breeding period for males. In addition, for females total food consumption was determined at the following intervals: day 0-7, 7-14, 14-20 of gestation and of days 0-7, 7-14 and 14-21 of lactation.
Compound intakes in parental animals were calculated during the pre-mating periods for each sex on a weekly basis.

Reproduction parameters
Oestrus cycle
The oestrus cycle was checked daily by microscopically examination of vaginal smears. Examinations were done for each female for one week prior to mating until copulation was confirmed.

Reproductive performance
Mating indices for males and females were calculated separately after copulation was confirmed. In addition, fertility and gestation indices, the length of gestation, as well as the number of implantation sites were determined.

Sperm assessment
An assessment of motility and morphology of epididymal sperm was done at necropsy for 10 males per group, which were selected for the organ weight measurement, as well as for males that failed to impregnate females.

Litter data
Total number of live and dead pups, and the number of males and females per litter were determined on day 0 of lactation. The sex ratio was calculated for each group. Viability indices were determined for each litter on lactation days 0, 4 and 21. Body weights were determined on lactation days 0, 4, 7, 14 and 21.
A check for clinical signs of toxicity and mortality was made once daily during the lactation period on all F1 and F2 pups. A detailed physical examination was done on lactation days 0, 4, 7, 14 and 21.

Sacrifice and pathology
All surviving parental F0 and F1 males and females were sacrificed on day 21 post partum and subjected to a gross pathological examination. Animals of all generations that died, were found dead or were killed moribund during the study period were necropsied as soon as possible. The following organs and tissues were preserved: adrenals, aorta, brain, caecum, colon, duodenum, epididymis, eyes, gross lesions, head (incl. nasal cavity, paranasal sinuses, buccal mucosa and ears), heart, ileum, jejunum, kidneys, larynx, liver, lung, mammary gland, oesophagus, ovaries, pancreas, pharynx, pituitary, prostrate, rectum, seminal vesicles, spleen, stomach, testes, thymus, thyroid/parathyroid, tongue, trachea, urinary bladder, uterus (cornua and cervix) and vagina.

F1 and F2 pups that were not selected on day 4 of lactation were also killed and necropsied on that day. In addition, F1 weanlings that were not selected for parental animals of the F1 generation and all F2 weanlings were necropsied at 22-26 and 21-26 days of their age, respectively. The same organs, as described above, were preserved from one animal per sex per litter of the F1 and F2 weanlings necropsied.

The following organs weights of 10 F0 and F1 males and females from each dose group that were sacrificed at the end of the study, as well as from pairs of parental animals that failed to mate: adrenal gland, brain, epididymides, kidneys, liver, ovaries, prostrate, pituitary, seminal vesicles (with coagulating gland and fluids), testes, uterus.
A histopathological examination was performed on the reproductive organs and pituitary of the control and high dose F0 and F1 parental animals that survived until scheduled termination. A histopathological examination of the reproductive organs and pituitary in the low and mid-dose group was only performed on pairs of animals that had failed to produce offspring.
In addition, a histopathological examination was performed on organs with significant weight change, and on all organs with gross pathological changes.

Statistics
One or a combination of the following statistical methods were applied for the evaluation of the measured parameters: Bartlett´s test for equality of variance (p=0.05) followed by parametric analyses of variance in one-way classification (p=0.05) or Dunnett´s t-test or Scheffé ´s multiple comparison test (p=0.05, 0.01 or 0.001); or Bartlett´s test followed by Kruskal-Wallis test (P=0.05) and Dunnett-type mean rank test or Scheffe-type mean rank test ((p=0.05, 0.01 or 0.001). Fisher´s exact probability test ((p=0.05, 0.01 or 0.001) and Mann-Whitney´s U-test (p=0.05 or 0.01) were also used.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS

Based on the results of the dose-finding study the chemical stability of the test substance in the was given for 5 weeks (at room temperature) in sealed plastic bags in the dark, and for at least 2 weeks after being released from the plastic bags.
Homogeneity of the test substance in the dietary mixtures was satisfactory, percentage deviations from the overall mean were within 4%. The mean achieved concentrations of HR-001 in the diet preparations were in the range of 90 – 105% of the nominal and therefore acceptable.

B. FOOD CONSUMPTION AND TEST COMPOUND INTAKE

F0 and F1 males

In F0 males, mean food consumption at treatment week 13 in the 1200 ppm group was significantly higher than that in the control group. Since there was no such increase observed in the mid- and high-dose groups throughout the study, this change was not thought to be treatment-related.
In F1 males in the 30000 ppm group, mean food consumption at treatment week 4 was significantly lower than that in the control group, but the values on the other treatment weeks in this dose group were comparable to the controls. In the 1200 and 6000 ppm groups, mean food consumption of F1 males was comparable to the controls throughout the study.

F0 and F1 females

In F0 females, the values on treatment weeks 2-4 in the 30000 ppm group were significantly higher than the controls. Inversely, the value on lactation days 7-14 in this dose group was significantly lower than those in the control group. So it was unclear these changes were treatment-related or not. In the 1200 and 6000 ppm groups, mean food consumption of F0 females was comparable to the controls throughout the study.
In F1 females in the 1200 and 6000 groups, mean food consumption on lactation days 14-21 were significantly higher than those in the control group. However, these changes were thought to be incidental because no such increase was observed in the highest dose group. In the 30000 ppm group, mean food consumption of F1 females was comparable to the controls throughout the study.

The group mean achieved dosages are summarised in Table 5.6.1-21 below.

Table 5.6.1-21: HR-001: A two-generation reproduction study in rats ([redacted], 1997): group mean achieved dose levels F0 and F1-generation

Group	Dietary concentration (ppm)	Mean achieved dose level (mg/kg bw/day)			
		Males		Females	
		F0	F1	F0	F1
Control	0	0	0	0	0
Low	1200	83.6	91.7	96.9	104.8
Intermediate	6000	417	458	485	530
High	30000	2150	2411	2532	2760

C. MORTALITY

F0 and F1 males

There were no treatment related mortalities in F0 or F1 males. During the study period, one F0 male and one Fl male in the control groups and one Fl male in the 6000 ppm group showed malocclusion of the incisors, respiratory wheezing, and red sebum. One of these animals (in the 6000 ppm group) also showed distention of the abdomen. These animals were euthanatised within several days after discovery due to unfavorable prognosis. Necropsy revealed a fracture of the facial bones in all cases, suggesting that the

alterations were caused by an accident in a cage.

F0 and F1 females
During the study period, no deaths occurred in any females of the F0 and Fl generations.

D. CLINICAL OBSERVATIONS
F0 and F1 males
There were no treatment-related clinical signs observed in the 1200 and 6000 ppm groups.
At 30000 ppm F0 and F1 parental males exhibited loose stool with incidences during the pre-mating growth and breeding periods of 3/24 and 2/24 for the F0 generation, and of 13/24 and 0/24 for the F1 generation, respectively, with a significant difference in the value for the pre-mating growth period of the F1 generation. Since this finding was not observed in other groups including control, defecation of loose stool was considered to be treatment-related.
Statistically significant differences were also observed in the incidence of hair loss during the breeding period for F0 males in all test substance groups. However, the occurrence of this change in the treated groups was rather lower than controls, and was considered to be incidental.
During the study period, one F0 male and one F1 male in the control group and one F1 male in the 6000 ppm group showed malocclusion of the incisors, respiratory wheezing, and red sebum. The aforementioned one F1 male of the 6000 ppm group also showed distension of the abdomen. These animals were euthanatised within several days after discovery due to unfavourable prognosis. Necropsy noted a fracture of the facial bones in all cases, suggesting that the alterations were caused by an accident in the cage. Accident malocclusion of incisors was also observed in one F1 male in the 1200 ppm group. However, test substance treatment of this animal was continued until termination of the study because its condition was improved.

F0 and F1 females
There were no treatment-related clinical signs observed in the 1200 and 6000 ppm groups. In F0 and F1 parental females, loose stool was also observed at 30000 ppm. The incidences during the pre-mating growth period and the lactation and post-weaning period were 1/24 and 6/24 for the F0 generation, and 4/24 and 2/24 for the F1 generation, respectively, with a significant difference in the value for the lactation and post-weaning period of the F0 generation.

E. BODY WEIGHT

F0 and F1 males

Mean body weights of F0 and F1 males in the 30000 ppm group were consistently lower than those in the control group from treatment week 1 to the day of necropsy, and the differences from controls at treatment weeks 1-12 and 14 for the F0 generation, and treatment weeks 1-6 for the F1 generation were statistically significant. In the 1200 and 6000 ppm groups, mean body weights of F0 and F1 parental males were comparable to the controls throughout the study.

Table 5.6.1-23: HR-001: Dietary Two Generation Reproduction Study in the Rat ([redacted], 1997): Selected body weights throughout treatment period – F0 and F1 males (group mean values)

F0 and F1 females

There were no significant differences in mean body weights of F0 females in any treatment group when compared to control. In F1 females in the 30000 ppm group, mean body weight on lactation day 0 was significantly higher than that in the control group. In the 1200 and 6000 ppm groups, mean body weights of F1 parental females were comparable to the controls throughout the study.

F. REPRODUCTIVE PARAMETERS

F0 males and females

Reproductive performance of F0 parental animals was not adversely affected by test substance treatment, and no significant differences were observed in such parameters as percentage of females having normal oestrous cycle, mating index, fertility index, gestation index, duration of gestation, number of implantation sites, and number, motility and morphology of epididymal sperm between the control group and the treated groups (Table 5.6.1-27a).

F1 males and females
In F1 parental animals, reproductive parameters in the treated groups were also comparable to the controls with the exception of gestation index and number of implantation sites, on which some biases were occasionally observed.
The significant higher number of implantation sites at 1200 ppm when compared to control was considered to be unrelated to treatment, since there was no increase noted at 6000 and 30000 ppm.
A similar bias was also found in the fertility index. The fertility indices in the control, 1200, 6000 and 30000 ppm groups were 95.8 (23/24), 95.8 (23/24), 87.5 (21/24) and 79.2% (23/24), respectively, with somewhat low values in the 2 higher dose groups. However, these decreases were considered to be incidental because the differences between the control and treated groups were not statistically significant, and because, as described below, normal reproduction results were obtained in the F1 parental animals, which had failed to produce offspring in this study, after remating with untreated animals.

Among the total of ten F1 females mated with untreated males, only one female in the 30000 ppm group did not undergo pregnancy. Histopathological of this female showed no abnormalities in the reproductive organs and pituitary. So the cause of infertility of this female was not known. The other nine F1 females were proved to have normal reproductive performance. One F1 male in each of the 1200, 6000 and 30000 ppm groups could not successfully impregnate untreated females mated. These 3 males had histopathological abnormalities in the testes and epididymides, and abnormalities in the sperm parameters, as a cause of infertility. However, the other 7 males were proved to have normal reproductive performance. Thus, the majority of F1 males and females which had failed to produce offspring were proved to have normal reproductive performance (see tables below).

G. LITTER DATA

Number of pups delivered
Mean number of F1 and F2 pups delivered in the 1200, 6000 and 30000 ppm groups were comparable to the controls.

Sex ratio
Sex ratios of F1 and F2 pups in the 1200, 6000 and 30000 ppm groups were comparable to the controls.

Viability index
The viability indices of F1 and F2 pups in the 1200, 6000 and 30000 ppm groups were comparable to the controls.

Body weights

F1 pups

There were no effects on mean body weight noted in the low- and mid-dose group when compared to controls. F1 pups of both sexes in the 30000 ppm group, showed significantly higher mean body weights on lactation day 0 than the controls. However, mean body weights on days 14 and 21 were significantly decreased when compared controls.

F2 pups

There were no effects on mean body weight noted in the low- and mid-dose group when compared to controls during the lactation period. In F2 pups in the 30000 ppm group, mean body weights of both sexes on day 21 of lactation were significantly lower than those in the control group.

Clinical signs
There were no treatment-related abnormalities noted in F1 and F2 pups of any dose group.

During the lactation period, deaths and loss due to maternal cannibalism occurred in several pups in all groups including the control. However, the incidences in the treated groups were comparable to the control.

I. PATHOLOGY
Necropsy
F0 and F1 generation
Necropsy of parental animals of both sexes noted several findings in all groups including the control group. Among these alterations, the incidences of distension of the caecum in F0 and F1 males and females of the 30000 ppm group were significantly higher than those of the controls, and were considered treatment-related. Statistically significant differences from controls were also found in the incidences of hair loss in F0 males of the 1200, 6000 and 30000 ppm groups. However, the values were rather lower than controls and were considered to be incidental. Other findings were low in their incidences and considered not treatment-related.

F1 and F2 pups
Necropsy of stillbirths found on lactation days 0, pups found dead during lactation days 1-4, and pups killed to reduce the litter size on lactation day 4 demonstrated no treatment-related abnormalities in any of the F1 and F2 pups.
During days 5-21 of lactation, only 2 F1 pups in the 1200 ppm group were found dead. Necropsy of these dead pups were not performed due to advanced autolysis.
Necropsy of F1 and F2 weanlings in the 30000 ppm group noted distension of the caecum, suggesting a treatment-related occurrence. In the 1200 and 6000 ppm groups, no treatment-related abnormalities were observed in any of the F1 and F2 weanlings.

Organ weights
F0 and F1 males:
There were no effects in the absolute and relative organ weights in F0 and F1 males of the low- and mid-dose groups. At 30000 ppm relative weights of the liver and kidneys of F0 and F1 males were significantly higher than the control values. These increases were considered treatment-related. In F1 males in the high-dose group, there was also a significant decrease noted in the absolute and relative weights of the prostate. Besides these changes, the relative brain weight of F0 males in the 30000 ppm group was significantly higher than the control value. However, this finding was considered to be the change associated with the low body weights in this group (Table 5.6.1-29a).

F0 and F1 females
In F0 females, the absolute and relative weights of all organs were comparable between the control and treated groups. In F1 females in the 30000 ppm group, the absolute and relative weights of the liver and kidneys were significantly higher than the controls, and these increases were considered treatment-related. Significantly higher-than-control value was also observed in the absolute kidney weight in the 6000 ppm group. However, this increase was not considered treatment-related because statistical significance in the difference between the control and 6000 ppm groups disappeared when all F1 females were subjected to

the weighing of the kidneys fixed in 10% neutral buffered formalin. The significant lower relative ovarian weight observed in F1 females in the 1200 ppm group was considered to be an incidental finding because no such decrease was observed in the mid- and high-dose groups (Tables 5.6.1-30a and -30b).

Histopathology
F0 and F1 generations
In all F0 and F1 males and females in the 30000 ppm group, histopathological examinations of the reproductive organs and pituitaries did not indicate any treatment-related alterations.

No treatment-related histopathological alterations were also evident in the following organs in which significant weight changes were detected: kidneys of F1 females in the 6000 ppm group; kidneys of F0 males and F1 males and females in the 30000 ppm group; and liver of F1 males and females in the 30000 ppm group.

III. CONCLUSIONS

Oral dietary administration of 0, 1200, 6000 and 30000 ppm glyphosate to Sprague-Dawley rats for two successive generations resulted in treatment-related signs of toxicity in parental rats at 30000 ppm. Therefore, the NOAEL for maternal toxicity is considered to be 6000 ppm, equivalent to 417-458 mg/kg bw/day and 485-530 mg/kg bw/day for males and females, respectively.
The NOAEL for reproduction is 30000 ppm, since the reproductive performance was not affected in any dose group. Based on the body weight effects and increased incidences of caecum distension the NOAEL for offspring is considered to be 6000 ppm.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Parental toxicity was observed at highest dose of 30000 ppm (> 2000 mg/kg bw/day) only and consisted of loose stool (F0/F1, m/f), reduced body weight (F0/F1, m) caecum distension (F0/F1, m/f), increased liver and kidney weights (F0/F1, m/f), decreased prostate weight (F1). Histopathological alterations were not detected.

Offspring toxicity was observed at highest dose level only and confined to reduced body weight and caecum distension in both sexes. Based on the results the NOAEL for parental and offspring toxicity was considered to be 6000 ppm (417-458 / 485-530 mg/kg bw/day) and 30000 ppm (2150-2411 / 2532-2760) for reproductive toxicity.

Assessment and conclusion by RMS:

Guidelines followed in study	OECD 416 (1983)
Deviations from current test guideline (OECD 416, 2001)	Missing endpoints: estrous cycle monitoring, pre-coital interval, sperm analysis, organ weights, monitoring of physical and sexual offspring development. Deviations from the current version of OECD 416 (2001) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 416.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities1,2	Yes
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

To evaluate the potential effects of glyphosate technical on reproduction groups of 30 Wistar rats per sex were fed diets containing test substance concentrations of 0, 100, 1000, and 10000 ppm (equivalent to 0, 7.7, 77 and 770 mg/kg bw/day) for two consecutive generations up to weaning of third (F2) generation.

First parental (F0) animals were treated for at least 8 weeks before mating. The first pairing produced the F1 litter from which the second parental generation was selected. All F2 litters were sacrificed at weaning. All groups were observed for clinical signs, body weight development, food consumption, mating behaviour, vaginal smear and pups observation (number, sex, survival and body weight). During gestation and lactation periods the dams were observed for body weight and food consumption. The data were statistically analysed. From all groups of parental (F0 and F1) rats, major visceral organs and reproductive organs were subjected to detailed gross necropsy. Lesions if any found in reproductive organs/tissues in all groups were subjected to histopathological examination. All pups were subjected to detailed gross pathology.

Dietary administration of glyphosate at up to 10000 ppm for two successive generations in Wistar rats showed no treatment and dose related significant and consistent changes in the incidence of clinical signs, mortality rate, body weight change and food consumption during treatment, gestation and lactation periods. No treatment and dose related consistent effects on number of pups born (combined and individual sex) and their growth were observed; however the total litter weight and female pup weight tended to be higher in treatment groups occasionally.

The reproductive performance parameters like (a) number of dams littered (b) number of dead pups at first observation (c) mean litter size; pup survival parameters like live birth index and survival index for 24 hours, day 4, 7, 14 and 21 and fertility index parameters for sires and dams have though shown some incidental significant changes compared to the control group; however, these changes were not consistent in both the generations and there was no relationship with treatment or the dose of the test compound in the diet.

In the two generation reproduction study conducted on glyphosate at dietary dose levels of 0, 100, 1000 and 10000 ppm no major effects on general health, growth of parents, gestation/lactation period, body weight and food consumption, gross necropsy findings of pups and parents were observed. The test compound did not cause any treatment or dose related consistent changes in parental mortality, parturition performance, mean litter size, pup weight and male and female fertility index.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Chemical name	N-(Phosphonomethyl) glycine
Description:	Odourless, white crystal
Batch #:	60
Purity:	96.8 %
Date of receipt	11/9/1990
Expiry date:	July 1992
Stability of test compound:	More than two years at ambient temperature
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Wistar rats (Random bred)
Source:	[redacted]
Age at start of treatment (F0):	8 weeks
Sex:	Males and females
Mean body weight at initiation of dosing:	Males: 160 - 190 g; females: 141 - 160 g
Acclimation period:	7 days
Diet/Food:	Standard "Gold Mohur" brand powdered rat feed manufactured by M/s Lipton India Limited, Bangalore, India
Water:	Deep bore well water passed through activated charcoal filter and exposed to UV rays (Aquaguard on-line water filter cum-purifier manufactured by M/s Eureka Forbes Limited, Bombay, India) was provided in glass bottles *ad libitum*
Housing:	Groups of five/three rats of same sex per cage depending on the size of the animals were accommodated in standard polypropylene rat cages (size: L 430 x W 270x H 150 mm) with stainless steel top grill; bedding material (paddy husk) was changed three times per week.
Environmental conditions:	Temperature: 22 ± 3 °C Humidity: 40-70 % Air changes: 10-15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: May 1991 to April 1992 (not further specified)

Animal assignment and treatment:
In a two-generation reproduction study groups of 30 Wistar rats per sex of the F0 generation received daily dietary doses of 0, 100, 1000 and 10000 ppm glyphosate technical in diet.
After at least 8 weeks of treatment pairing of animals within each dose group was undertaken on a one male:one female basis, to produce the F1 litters. The day of proved copulation (vaginal smear) was designated day 0 of gestation. On day 4 post partum, litter sizes were reduced to a maximum of 8 pups, preferable to 4 males and 4 females, and the remaining pups were culled. Weaning was done on day 21 of lactation and all F0 parental animals were sacrificed. Groups of 30 male and 30 female offspring from each dose group of the F0 generation were selected to form the F1 parents.
The offspring selected for the F1 generation were paired within each dose group to produce the F2 litters. F2 litters were weaned on day 21 of lactation and terminated together with F1 parental animals.

Diet preparation and analyses
The required quantities of test compound were weighed and mixed manually with 1.0 kg of powdered rat feed to prepare the premix. The premixes were added to the bulk of remaining quantities of feed and mixed in ribbon mixer. Prepared feed bulks were sampled at different intervals for assaying test compound concentration in experimental diet. Frequency of feed mixing was once a fortnight.

Clinical observations
All animals were observed daily throughout the study and any visible clinical signs were recorded with details on type, severity, time of onset and duration. Any animal found dead or sacrificed in extremis was necropsied and macroscopically abnormal tissues were retained.

Body weight
Males were weighed weekly until termination. Females were weighed weekly during pre-mating, on gestational days 0, 6, 13, and 20 and on days 1, 4, 7, 14 and 21 of lactation.
Offspring were weighed sex-wise as litters on days 1, 4, 7, 14 and 21 post partum.

Food consumption and compound intake
Food consumption for each cage of males was recorded weekly until termination. Food consumption of females was recorded weekly during pre-mating and at the following intervals: days 0-6, 6-13, 13-20 of gestation and days 1-4, 4-7, 7-14 and 14-21 of lactation.

Mating procedure and vaginal smears
After the scheduled period of treatment (minimum of 8 weeks), females were paired on a one-to-one basis with males from the same treatrnent group. Each morning following pairing, a vaginal srnear was prepared from each fernale and examined for the presence of spermatozoa indicating mating. The day on which evidence of mating was found was designated as day 0 of gestation. Once mating had occurred, rnales were separated from females and vaginal smearing was discontinued.
Females not mated within seven days of pairing were removed and placed with another male of the same treatment group. This was repeated once again, if needed, thus allowing each female a maximum of 21 days to get rnated . Matings of siblings were avoided by pairing males and females of different litters in each generation . Same mating procedure was adopted in Fl animals after 13 weeks of dietary regime.

Pre-coital interval
The time elapsed between initial pairing and detection of mating was noted.

Duration of gestation
The time elapsed between detection of mating and parturition was recorded.

Reproduction parameters

Reproductive performance
The following reproductive indices were recorded: Male and female fertility index, fecundity index, mean number of implantations, parturition percentage, percentage mortality of pregnant dams, percentage of live pups born, in females the pre-coital interval (time elapsed between initial pairing and detection of mating) and duration of gestation.

Litter data
Total number of live and dead pups, viability indices (mean viable litter size on day 0, live birth index), litter weight, individual sex and observations on individual pups (if any) were determined within 24 hours after birth. Survival indices were determined on days 2, 4, 7, 14 and 21 of lactation. Body weights were determined on Lactation days 0, 4, 7, 14 and 21. A check for clinical signs of toxicity and mortality was made once daily during the lactation period on all F1 and F2 pups. On day 4 post partum, offspring were culled to reduce litter size to eight.

Assessment of development and reproductive performance of progeny
Following weaning, 30 male and 30 female offspring from the Fl litters were selected to form the second generation (P1) parents. When possible, one male and one female were selected from each litter using random numbers within litters after grossly atypical animals were excluded. When litters were insufficient to provide 30 males and 30 females in each group, additional offspring were randomly selected as above from litters already used within each group.The experimental conditions and serial observations made were same as described for the first generation (P0).

Sacrifice and pathology
All surviving parental F0 and F1 males and females and the non-selected weanlings from F1 and all F2 weanlings were sacrificed and subjected to a gross pathological examination. Tissue collection was done for animals of the parent generations only. Animals of all generations that died, were found dead or were killed moribund during the study period were necropsied as soon as possible.
The following organs and tissues were preserved from all F0 and F1 parents of all groups: Ovaries, uterus, vagina, testes, epididymides, seminal vesicles, prostate, coagulation glands, pituitary, adrenals, liver and kidneys. The organs were examined for gross pathological changes and those found abnormal were examined histopathologically.
Females failing to get mated within 21 days and females failing to produce a viable litter by day 25 post coitum were necropsied and any macroscopically abnormal tissue was retained for histopathological examination. The presence of corpora lutea, implantations and resorptions was examined in females which had failed to produce a viable litter.
On day 4 post partum, offspring were culled to reduce litter size to eight, where possible; culled offspring or found dead were necropsied. All F2 pups were sacrificed at weaning.

Statistics
One or a combination of the following statistical methods were applied for the evaluation of the measured parameters: Dunnett's t-test (for body weight, food consumption, litter number, litter weight, gestation and lactation period), Z Test (for mating performance, fertility index, gestation index, live birth index, viability index, lactation index, pups survival data, number of dead pups at birth, survival indices, number littered) and t/r test (for dose-response relationship).

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
In-house stability study for glyphosate technical was carried out at 0, 2000 and 20000 ppm. Chemical stability was given for 30 days at room temperature with a loss of less than 7% at 0, 2000 and 20000 ppm levels in experimental diet when stored in polyethylene lined stainless steel drums.
The mean achieved concentrations of glyphosate in the diet preparations were analysed; the achieved concentrations were in the range of 96-100 % of the nominal and therefore acceptable.

B. TEST COMPOUND INTAKE

Test compound intake at 100, 1000 and 10000 ppm was estimated to be 7.7, 77 and 770 mg/kg bw/day, respectively.

C. MORTALITY

F0 and F1 males

There were no mortalities in male animals.

F0 females

In the females, there were three mortalities, two in the low dose group, (one dystokia and one suppurative pneumonia) and one in the high dose group (cause of death not ascertained).

F1 females

One dam in low dose group died of dystokia.

D. CLINICAL OBSERVATIONS

F0 generation

Nasal discharge and snuffling and cannibalism were seen in all groups. No other treatment related changes in clinical signs were observed.

F1 generation

The incidence of clinical signs was low and not treatment or dose related. There was no incidence of total cannibalism and the incidence of partial cannibalism was similar in all study groups.

E. BODY WEIGHT

F0 males

Initial body weight of treatment groups was higher compared to the control group and this trend continued during the entire treatment period. The absolute weight gain (difference between initial and terminal) during entire treatment period was similar to control group in low and high dose while in mid dose it was slightly higher.

F0 females

No significant treatment related differences were noted between treated and control groups.

F1 males
Mid dose group body weight (both initial and in subsequent weeks) was more than control. In high dose group initial body weight (Week 0) was higher than control but at Week 2 and 3 it was less. However in this group the body weight tended to be higher (not significant) during last seven weeks.

F1 females
The body weight of all treatment groups at selection (Week 0) was higher than in the control group and continued to be significantly higher than in the control group for up to Week 10 in mid and high dose groups. Body weights of the high dose group dams on Days 0, 6 and 13 of gestation period were significantly higher compared to controls but the body weight gain was statistically not significantly different. Another incidental significant finding was higher body weight (Gestational Day 0-20) of mid dose group dams compared to controls. Absolute body weight of mid dose group on Lactation Days 1 and 4 and that of high dose group during all periods of lactation was significantly higher than in control group. The mid dose group had lost body weight during Days 7-14, 14-21 and 1-21 of lactation period as compared to control.

F. FOOD CONSUMPTION

F0 parents

Mean food consumption of males was similar to the controls throughout the study. High dose female animals tended to consume significantly more food than controls during gestation. During lactation low and mid-dose females consumed significantly less than controls, especially for the Periods 7-14 and 14-21. High dose females consumed significantly more food for Lactation Days 4-7 as compared to controls.

F1 males

Treatment groups did not show consistent and dose related changes as compared to control group. However initially (Weeks 0-2) mid and high dose groups consumed significantly less feed and later on a few occasions mid dose group showed increased consumption.

F1 females

Treatment group dams did not show treatment and dose related consistent difference from control group; on a few occasions the treatment groups showed both increased/decreased food consumption over control. During gestation there was no statistically significant inter group difference in feed consumption between control and treatments during gestation period. Low dose dams consumed significantly less food than controls during different lactation periods (except for Day 7 and Period 7-14). Mid and high dose group dams did not show any treatment and dose related changes over control except for an incidental finding of increased and decreased feed consumption on Day 7, 14 and Period 7-14 and 14-21 respectively in mid dose group.

G. REPRODUCTIVE PARAMETERS

Reproductive performance parameters of F0 parental animals such as female fertility index, number of implantations, gestation index, duration of gestation and live birth index were not significantly different between treated and control groups. Male fertility index was significantly higher in low and high dose groups over control.

F0 generation
On Day 1 of lactation, mean litter size was significantly less than control in low and mid dose groups and the mean viable litter size at birth was significantly less in low dose group; the number of live pups on Day 1 was significantly lower in the mid-dose group.

F1 generation
Reproductive performance parameters of F1 parental animals such as male and female fertility index, fecundity index, parturition percentage and mortality of pregnant dams was not different between treatment and control groups. The incidence of dams not littered tended to be higher in the mid-dose group compared to controls. A significantly decreased number of implantations was observed in low and mid dose groups; the percentage of live pups born was significantly reduced in the in mid dose group and significantly increased in the high dose group.

H. LITTER DATA

Number of pups delivered

Mean number of F1 and F2 pups delivered and mean litter sizes in the 100, 1000 and 10000 ppm groups were comparable to the controls.

Sex ratio
Sex ratios of F1 and F2 pups in the 100, 1000 and 10000 ppm groups were comparable to the controls.

Viability index
F1 pups
In the low dose group the pup survival index for Days 4, 14 and 21 was significantly lower than in controls. In the mid dose group the live birth index and Day 14 survival index were higher and Day 4 survival index was lower compared to controls. In the high dose group on Day 14 and 21 survival index was higher than in controls. Dose response relationship was not seen in these parameters.

F2 pups
There were no statistically significant inter group differences between control and treatment groups in parameters of F2 litters at first observation including incidence of external abnormalities in pups. The mean number of pups (combined and individual sex) during different periods of lactation did not show statistically significant differences compared to control group.
The group mean values of pup survival data parameters like: live birth index, 24 hours survival index and survival index for Days 4, 7, 14 and 21 did not show any significant inter group difference between control and treatment groups.

Body weights
F1 pups
Mean litter weight of combined sex and female pups in treatment groups were significantly more than control group on Day 1 and 4, respectively. On Day 7 combined sex litter weight and male pup weight was significantly less than control in low dose group while in high dose group it was more than control group. On Day 21 the mean body weight of complete litter and individual sex pups of mid dose group were more than control group. None of these showed any apparent dose response relationship.

F2 pups
Combined sex litter weight on day one and that of female pups of all treatment groups was higher than in controls; in addition combined sex litter weight in low and mid dose groups and that of male and female in mid dose group was higher than control on Day 4. In high dose group the male pup body weight on Day 14 and 21 was lower than control. None of these parameters showed any dose response relations.

Clinical signs
There were no treatment-related abnormalities noted in F1 and F2 pups of any dose group.
During the lactation period, deaths and loss due to maternal cannibalism occurred in several pups in all groups including the control. However, the incidences in the treated groups were comparable to the control.

I. PATHOLOGY

Necropsy

F0 generation

The gross pathological lesions seen were consolidated lungs with ecchymoses, chronic liver changes, kidneys with cysts and dilated pelvis, and hypoplastic testes (1 in the control group, 2 in the mid-dose and 1 in the high-dose group). The incidence was low and did not appear to be compound or dose related.

F1 generation

The gross pathological lesions seen were consolidated and collapsed lungs with emphysema, hydronephrotic kidneys, and unilateral hypoplastic testes. The lesions observed were few and appeared to be incidentally. A single incidence of unilateral testicular hypoplasia was observed in each of the three treatment groups, hydronephrosis was seen in two animals in the high dose group.

F1 pups

A higher incidence of emaciated pups was recorded for the mid and high dose groups compared to controls. A low incidence of minor developmental abnormalities like kinked tail, rudimentary tail, kidney hydronephrosis and dilated pelvis occurred without dose-response relation.

Table 5.6.1-44 Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted] 1993): Summary of necropsy findings F1 pups

Histopathology
F0 generation
Reproductive organs showing gross pathological changes were recorded as outlined in the following: testes from one control animal, two mid dose and one high dose animal. The control and high dose animals showed degenerative changes in the seminiferous tubules while the mid dose group did not show this finding. These changes appeared to be incidental and not compound related.

Table 5.6.1-46 Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted] 1993): Summary of histpopathological fings – F0 males

Observations	Dietary concentration (ppm)			
	0	100	1000	10000
No. of tissues evaluated	1	0	2	1
Testes				
Degenerative changes – seminiferous tubules	1	0	0	1

F1 generation
Reproductive organs showing gross pathological changes were recorded as outlined in the following: testes from one animal in each of the three treatment groups; the testes in the low and mid dose groups showed unilateral degenerative changes and giant cell formation in the seminiferous tubules and focal chronic inflammation. The testes in the high dose were normal though unequal in size. The changes appeared to be incidental and not compound related.

Table 5.6.1-47 Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted] 1993): Summary of histpopathological fings – F1 males

Observations	Dietary concentration (ppm)			
	0	100	1000	10000
No. of tissues evaluated	0	1	1	1
Testes

Giant cell formation - seminiferous tubules	0	1	1	0
Infammation – chroni focal	0	1	1	0

III. CONCLUSIONS

Study conclusion:
The oral administration of glyphosate to rats by dietary admixture at a maximum dose level of 10000 ppm for two successive generations of Wistar rats resulted in no parental toxicity. The NOAEL for reproduction is considered to be 10000 ppm, since the reproductive performance was not affected in a dose-related manner. The NOAEL for offspring is 10000 ppm, since no treatment-related effects on offspring were observed.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The highest dose of 10000 ppm is considered to be the NOAEL for parental, reproductive and offspring toxicity. This dietary level would correspond to a mean daily compound intake of 700-800 mg/kg bw/day.

Assessment and conclusion by RMS:

2. Full summary

Glyphosate technical was administered by dietary admixture to three groups of 28 male and female F0 generation Sprague-Dawley rats each at dietary concentrations of 1000, 3000 and 10000 ppm (equivalent to a mean achieved dosages of 66.4 – 76.1, 196.8 – 230.2 and 668.1 – 771.3 mg/kg bw/day for males and 75.3 – 82.1, 226 – 244.9 and 752.3 – 841.1 mg/kg bw/day for females, respectively). An additional group of 28 male and 28 female F0 animals was exposed to basal laboratory diet to serve as a control.

Each parent generation was mated to produce two litters. Offspring from the first litters of the F0 parents (F1A litters) were selected to be parents for the F2 generation (24/sex/group). Offspring not included in the selection procedure and offspring from the second litter of each generation (F1B and F2B) were sacrificed at Day 21 post partum and given a gross post mortem examination. Parent animals were sacrificed shortly after termination of the second litter.

Clinical signs, body weight development, food and water consumption, mating performance, pregnancy rate, and length of gestation of adults were monitored during the study. Litter weight, individual offspring weights and landmark developmental signs were also recorded on specific days post partum. All animals at termination were subjected to a gross necropsy examination and weighing of selected organs and histopathological evaluation of selected tissues for the F0 and F1 adults was performed.

Treatment at 10000 ppm produced marginal signs of toxicity in parent animals and minimal histological changes in the target organ (salivary gland). Histological changes in the salivary gland were also noted at 3000 ppm. This finding is considered to be an adaptive response due to oral irritation from the ingestion of glyphosate, an organic acid, in the diet and is not considered to be adverse. In the offspring no treatment-related effects were apparent at dietary administration up to 10000 ppm.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White solid
Lot/Batch #:	206-Jak-119-1
Purity:	99.2%
Stability of test compound:	Stable during the treatment period.
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Sprague-Dawley Crl:CD (SD) BR VAF/Plus
Source:	[redacted]
Age:	Approximately 6 weeks
Sex:	Males and females
Weight at dosing:	Males: 143 – 201 g; females: 106 – 175 g
Acclimation period:	At least 15 days
Diet/Food:	Biosure Laboratory Animal Diet No.2, ad libitum
Water:	Tap water, ad libitum

Housing:	During pre-mating periods, animals were housed in groups of four in metal cages with wire mesh front, floor and top. During the first week of F1A and contingency animals of F2B animals were housed in plastic cages. During mating animals were housed on an 1:1 basis in plastic cages where females stayed after mating for breeding. Males were re-housed in former metal cages.
Environmental conditions:	Temperature: 23 ± 4°C Humidity: 45 ± 24% Air changes: not reported 12 hours light/dark cycle

B. STUDY DESIGN
In life dates: 1990-03-14 to 1991-03-22

Animal assignment and treatment:
In a two-generation reproduction study groups of 28 Sprague-Dawley rats per sex of the F0 generation received daily dietary doses of 0, 1000, 3000 and 10000 ppm glyphosate technical. The dose levels were chosen based on results of a previously conducted study (CA 5.6.1/009). In this study, treatment at 3000, 10000 and 30000 ppm was associated with signs of maternal toxicity, whilst effects on development of the offspring to 6 weeks of age was not affected up to 10000 ppm. After at least 70 days of treatment pairing of animals within each dose group was undertaken on a 1:1 basis to produce the F1 litters. At Day 21 post partum of offspring from the F0 mating phase, groups of 24 male and 24 female offspring from each dose group were selected to form the F1A generation. The remaining pups were sacrificed. Approximately 10 days following the weaning of all F1A pups, F0 males and females were re-mated. At Day 21 post partum all F1B pups were sacrificed. F0 males and females were terminated shortly after weaning of F1B pups.
The selected F1A animals were dosed from approximately Week 4 of age for at least 84 days and then mated on a 1:1 basis (sibling pairings were avoided). On Day 4 post partum F2A litters were standardised to 8 pups per litter. The remaining pups were sacrificed. On or shortly after Day 21 post partum all F2A pups were sacrificed. Approximately 10 days following the weaning of all F2A pups, F1 males and females were re-mated. On Day 4 post partum F2B litters were standardised to 8 pups per litter. The remaining pups were sacrificed. On or shortly after Day 21 post partum all F2B pups were sacrificed. F1 males and females were terminated shortly after weaning of F2B pups.

Diet preparation and analyses
For the weekly preparation of diet mixtures a known amount of the test substance was mixed with a small amount of basal diet. This pre-mix was then added to larger amount of basal diet and blended for further 7 minutes in a rotary double-cone-blender. Fresh diet was prepared weekly and fed for no more than 15 days from the date of preparation.
The stability and homogeneity of the test material in diet were determined. Dietary admixtures were analysed for achieved concentration throughout the study.

Clinical observations
A check for clinical signs or ill health was made once daily and recorded daily for the first week of treatment and on a weekly basis thereafter. Rats showing marked signs of ill health or reaction to treatment were killed and subjected to necropsy.

Body weight
Individual body weights were recorded at the start of each generation (F0: Week 6 of age; F1A: Week 4 of age) and subsequent at weekly intervals. Females were weighed daily during mating and continued until parturition. Weights were reported for Days 0, 7, 14, 17 and 20 of pregnancy. Females with live litters were weighed on Days 0, 7, 14 and 21 post partum.

Food consumption and compound intake
Food consumption was recorded on a weekly basis from allocation throughout the first pre-mating phase of each generation. During this period food conversion ratios and achieved intake (mg/kg bw/day) were calculated.

Water consumption
Water intake was observed daily during the initial and final two weeks of the first pre-mating period for each generation and from allocation for the F0 generation.

Reproduction parameters
Vaginal smears were taken daily during the 20–day mating period to examine the oestrus cycle and median pre-coital time. Additionally, date of mating and duration of gestation was recorded.

Litter data
The number of offspring born and the number of offspring alive were recorded daily. Pups were weighed on Days 0 and 4 and all litters containing more than eight pups were culled to eight on Day 4 post partum, retaining, where possible, ideally 4 pups per sex. The remaining pups were also weighed on Days 8, 12, 16 and 21. Dead and culled young were subjected to necropsy.

Sacrifice and pathology
All adult animals were subjected to a full external and internal examination, and any macroscopic abnormalities were recorded.

The following organs were weighed of adults: adrenals, brain, heart, kidneys, liver, lungs, ovaries, prostrate (with seminal vesicles and coagulating gland), testes (with epididymides), thymus.

The following tissues were preserved from all adults: adrenals, aorta, bone (femur and joint), bone marrow (sternum), brain, cranial vault (for lachrymal glands, teeth, nasal turbinates, inner ear), caecum, colon, duodenum, eyes, heart, ileum, jejunum, kidneys, liver, lungs, lymph nodes (cervical/mesenteric), mammary gland, macroscopically abnormal tissues, oesophagus, ovaries*, pancreas, pituitary*, prostate with seminal vesicles (with coagulating gland)*, rectum, salivary gland, sciatic nerve, skeletal muscle, skin, spinal column (vertebral column), spleen, stomach, testes (with epididymides)*, thymus, thyroids (with parathyroids), tongue, trachea (with larynx and pharynx), urinary bladder, uterus (with cervix)* and vagina*.

Histology of the reproductive tract was restricted to adults of the control and high-dose group and any apparently infertile animals at the lower dietary concentrations and confined to tissues marked with an asterisk (*).

Statistics
Two tailed significance tests were performed on adult parameters (water consumption, food consumption, body weight, organ weights) and litter data. Evaluation of other parameters were found not to be useful. Significances at 1% and 5% were reported.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
Stability analyses indicated that the dose preparations at nominal concentrations of 500 and 30000 ppm were stable for up to 18 days during storage under animal room conditions.
Analyses for homogeneity at nominal concentrations of 500 and 30000 ppm indicated that the dose preparations were homogeneous.
Analyses for achieved concentration performed at 4-5 weekly intervals demonstrated that the prepared

dietary admixture concentrations given to the animals were within ± 15% of the nominal concentration in all groups.

B. TEST COMPOUND INTAKE

The group mean intakes of glyphosate are summarised in the tables below.

Table 5.6.1-48 Glyphosate technical: The Effect of Dietary Administration of Glyphosate on Reproductive Function of Two Generations in the Rat ([redacted], 1992): Group mean achieved intakes of glyphosate - F0 generation

Group	Dietary concentration (ppm)	Mean intakes (Week 1 - 10) (mg/kg bw/day)	
		Males	Females
Control	0	0	0
Low	1000	66.4	75.3
Intermediate	3000	196.8	226.0
High	10000	668.1	752.3

Table 5.6.1-49Glyphosate technical: The Effect of Dietary Administration of Glyphosate on Reproductive Function of Two Generations in the Rat ([redacted], 1992): Group mean achieved intakes of glyphosate - F1 generation

Group	Dietary concentration (ppm)	Mean intakes (Week 5 - 16) (mg/kg bw/day)	
		Males	Females
Control	0	0	0
Low	1000	76.1	82.1
Intermediate	3000	230.2	244.9
High	10000	771.3	841.1

C. MORTALITY

There were no test substance related mortalities.

Four unscheduled deaths occurred during each generation.

In the F0 generation one female of the low dose group and one male of the high dose group were killed for humane reasons during Week 15 and 23, respectively. The female exhibited pilo-erection and thin appearance and the necropsy noted thickened forestomach, invaginated stomach and abnormal contents in the gastro-intestinal tract. The male was unable to use hind limbs, exhibiting aberrations of brain and spinal cord at necropsy. Another male of the high dose group died during Week 3, with effects on pancreas and liver noted at necropsy. One control male was sacrificed during Week 16 following poor condition, however, the actiology of the signs was not established.

In the F1 generation one female of the low dose group was killed following a procedural error. In the mid dose group one male died during Week 34 but autolytic changes precluded a valid necropsy. Moreover, one male and one female died and were sacrificed, respectively, during Week 23. Necropsies failed to identify a specific cause of death.

D. CLINICAL OBSERVATIONS

No treatment-related clinical signs of toxicity were noted. General signs were observed in occasional animals from both generations and were not related to treatment.

E. BODY WEIGHT

No adverse effect of body weight change was evident for treated animals in comparison to controls for both generations.

However, absolute mean body weights in high dose F1 males were slightly lower as compared to control. In addition it was noted that during the first mate of each generation, body weight gains during the initial stages of pregnancy tended to be slightly lower than controls at all dietary levels. Since no consistent dose-response was apparent these effects cannot conclusively be attributed to treatment.

2 Second mating commenced

F. FOOD AND WATER CONSUMPTION

Apart from a slightly higher but not statistically significant food consumption of high dose F1 females during the second half of the pre-mating period, there were no marked intergroup differences in food consumption of males or females. Across both generations, there were no clear or consistent adverse effects of treatment on the food conversion ratio, indicating that treatment with glyphosate does not overtly affect the efficiency of food utilisation into body weight of either sex at dietary concentrations of up to 10000

ppm.

Apart from a slight increase among high dose F1 females (attaining statistical significance in Week 16), no overt intergroup differences in water intake for treated males and females from the F0 or F1 generations when compared to their concurrent controls.

G. REPRODUCTIVE PARAMETERS

There were no treatment-related effects on mating performance, fertility and gestation length for both F0 and F1 generation animals.

H. LITTER DATA

Size and Viability

No overt differences in litter viability were detected.

In the high-dose group total litter size at birth was consistently, but not significantly, lower than controls across all four matings and remained lower than controls at Day 4 in three of the four matings. Since the mean litter size at birth within each mating, was not always the lowest litter size recorded, this finding could not be clearly attributed to treatment.

Growth and Development

No adverse effects on mean offspring body weights, body weight change or development were detected for male and female offspring in comparison to their controls.

1 In the report, this value was given incorrectly as 39.9. This was already noted by the RMS in RAR 2015. Recalculation by the RMS resulted in the given value (double-checked for accuracy).

Clinical signs
No clinically observable signs of toxicity were observed for offspring from treated animals.

I. PATHOLOGY

Necropsy
There were no toxicologically significant macroscopic abnormalities detected in the F0 and F1 animals, or offspring.

Organ weights
There were no overt or statistically significant treatment-related changes in any organ weights analysed in either generation.

Histopathology
No treatment-related changes in tissues associated with the reproductive tract were detected in the F0 or F1 generation animals.

Examination of two previously identified target organs, the parotid and submaxillary salivary glands, was initially performed only in the control and high-dose groups. Due to effects seen in the parotid gland, examination was extended to the remaining treatment groups. For the submaxillary gland, examination was extended to only the F0 and F1 females in the low- and mid dose group. The findings are summarised in the table below.

Table 5.6.1-59 Glyphosate technical: The Effect of Dietary Administration of Glyphosate on Reproductive Function of Two Generations in the Rat ([redacted], 1992): Incidence of salivary gland findings

Observation	Dietary concentration (ppm)							
	Males				Females			
	0	1000	3000	10000	0	1000	3000	10000
F0 Generation								
Animals examined	27	28	28	26	28	27	28	28
Hypertrophy of acinar cells with prominent granular cytoplasm (minimal)								
parotid	2	2	3	12	0	2	5	17
submaxillary	0	-	-	0	0	1	4	14
F1 Generation								
Animals examined	24	24	23	23	24	23	24	23
Hypertrophy of acinar cells with prominent granular cytoplasm (minimal)								
parotid	1	0	4	11	0	0	4	9
submaxillary	0	-	-	0	0	0	0	3

- = not examined

Treatment-related minimal changes were apparent in the parotid salivary gland of both F0 and F1 males and females in the mid- and high-dose groups and the submaxillary salivary gland of the F0 females in the mid- and high-dose groups and F1 females in the high-dose group. This finding is similar to those seen occasionally in other subchronic and long-term dietary studies and is considered to be an adaptive response due to oral irritation from the ingestion of glyphosate, an organic acid, in the diet and is not considered to be adverse (see CA 5.8.2/002). There were no effects on the salivary glands noted in the low-dose group.

III. CONCLUSIONS

Study conclusion:

The oral administration of glyphosate technical to rats by dietary admixture at a maximum dose level of 10000 ppm for two successive generations resulted in minimal effects consisting of increased food and water consumption of F1 females, possibly reduced body weights of F1 males and minimal histological changes in the target organ (salivary glands) in F0 and F1 adults at 10000 ppm. The only findings associated with treatment at 3000 ppm were minimal histopathological changes of the salivary glands in F0 and F1 adults. No effects were apparent at 1000 ppm. Thus, the parental reproductive and offspring NOAELs are considered to be 10000 ppm, corresponding to 668 and 752 mg/kg bw/day in males and females, respectively.

3. Assessment and conclusion

Assessment and conclusion by applicant:

No evidence of reproductive effects was observed. The only findings associated with treatment at 3000 ppm were minimal histopathological changes of the salivary glands in F0 and F1 adults considered to be an adaptive response due to oral irritation from the ingestion of glyphosate, an organic acid, in the diet and is not considered to be adverse (for mechanistical studies on salivary gland effects see also section 5.8.2). No effects were apparent at 1000 ppm. Thus, the parental reproductive and offspring NOAELs are considered to be 10000 ppm, corresponding to 668 and 752 mg/kg bw/day in males and

females, respectively.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/009**
Report authors	[redacted], A.J. *et al.*
Report year	1991
Report title	Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring
Report No	CHV 42/90619
Document No	Not reported
Guidelines followed in study	Not applicable for this dose-range finding study
Deviations from current test guideline	Not applicable
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	No (dose-range finding study)
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

In this preliminary assessment of the effect of glyphosate on pregnancy of the rat and postnatal development of the offspring, glyphosate was present in the diet of 10 time-mated females per group at 0 (Control), 3000, 10000 and 30000 ppm from Day 3 of pregnancy through to termination of the study. All females were allowed to litter and rear their young to weaning, when 10 male and 10 female offspring per group were selected and reared on their respective diets to six weeks of age. The duration of the study was 10 weeks. Diets were not analysed for homogeneity, stability or achieved concentration of the test compound as satisfactory data concerning homogeneity and stability in rodent diet were already available to the Sponsor.

Treatment at 30000 ppm was associated with the following maternal findings: one mortality, signs of soft faeces and yellow stained sawdust in all animals, slightly increased water consumption towards the end of pregnancy retarded body weight gain during the first two weeks of pregnancy and the second half of lactation, macroscopic salivary gland changes in 8/9 animals, macroscopic gastro-intestinal changes in 8/9 animals marked granular basophilic cytoplasm of acinar cells and moderate hypertrophy of acinar cells in all animals and a prominent mitoses in acinar cells of 2/9 animals. Offspring findings included a reduction in litter and mean pup weight, most evident from Day 8 post partum through to Day 21 post partum. Among offspring retained to six weeks of age, loose faeces, reduced food intake and food conversion ratio and, in males only, a slight continuation of the reduced weight gain evident from birth to weaning. Findings at post mortem examination included macroscopic changes to the salivary gland in 5/10 males and 2/10 females and gastro-intestinal disturbances in 7/10 males and 9/10 females.

Treatment at 10000 ppm was associated with the following maternal findings: signs of soft faeces and yellow stained sawdust in all animals, slightly lower body weight gain by Day 14 of pregnancy and during the second half of lactation, macroscopic salivary gland changes in 6/10 animals, macroscopic gastro-intestinal changes in 8/10 animals, moderate/marked granular basophilic cytoplasm of acinar cells and

minimal/moderate hypertrophy of acinar cells in all animals. No adverse effects on development of the offspring from birth to 6 weeks of age were noted, although 4 pups sacrificed at weaning had congested salivary glands.

Treatment at 3000 ppm was associated with the following maternal findings: slightly lower body weight gain by Day 14 of pregnancy, macroscopic salivary gland changes in 2/9 animals, macroscopic gastro-intestinal changes in 5/9 animals, minimal granular basophilic cytoplasm of acinar cells in 2/10 females with minimal hypertrophy of acinar cells in 2/10 females. No adverse effects on development of the offspring from birth to 6 weeks of age were noted, although one pup sacrificed at weaning and one male sacrificed at six weeks of age had congested salivary glands.

Assuming that effects seen in this preliminary study are representative of those that would occur in a comparable multiple generation study, a possible high level for the main study would appear to be less than 30000 ppm but greater than 10000 ppm, with a low level being less than 3000 ppm.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White solid
Lot/Batch #:	206-Jak-25-1
Purity:	98.6%
Stability of test compound:	Stable for at least 5 years
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	Sprague-Dawley Crl:CD (SD) BR VAF/Plus strain
Source:	[redacted]
Age:	Approximately 8 - 10 weeks
Sex:	Females
Weight at dosing:	214 - 216 g
Acclimation period:	3 days
Diet/Food:	Labsure LAD No. 2, ad libitum
Water:	Tap water, ad libitum
Housing:	Prior to parturition in groups of five in suspended galvanised metal cages (Bowman ®) equipped with solid sides and back, wire mesh front, floor and top. On Day 20 of pregnancy the rats were re-housed in individual plastic breeding cages (North Kent Plastics, RM-2 type) for the birth and rearing of young. Suitable nesting material was provided. Following weaning, the selected pups were housed by sex, five to a cage. During the first week post weaning plastic cages were used; subsequently, the animals were transferred to metal (Bowman ®) cages.

Environmental conditions:	Temperature:	20 – 23.5 °C
	Humidity:	39 – 62%
	Air changes:	no reported
	Light regime: 12/12 hours	

B. STUDY DESIGN

In life dates: 1989-11-11 to 1990-01-12

Animal assignment and treatment:
In a dose-range-finding study for a subsequent two-generation reproduction study groups of 10 time-mated Sprague-Dawley rats received daily dietary doses of 0, 3000, 10000 and 30000 ppm glyphosate in diet from Day 3 of gestation through gestation and lactation to termination at the end of lactation. These concentrations were equivalent to glyphosate intakes during gestation ranging from 236 - 311, 799 - 1010 and 2515 -2789 mg/kg bw/day in the low, mid and high dose, respectively. Control animals received the base diet alone. All females were allowed to litter and rear their young to weaning, when 10 male and 10 female offspring per group were selected and reared on their respective diets to six weeks of age.

Diet preparation and analyses
The test material as supplied was weighed out and added to a weighed amount of sieved Labsure Laboratory Diet No. 2, and stirred by hand to give a premix of suitable strength. The dietary concentrations required were obtained from this premix by direct dilution with further quantities of diet, homogeneity being achieved by mixing in a rotary double cone blender. Fresh diet was prepared weekly and fed for no more than 7 days from date of preparation and was stored until use in labelled opaque bags.
Diets were not analysed for homogeneity, stability or achieved concentration of the test compound since satisfactory data concerning homogeneity and stability in rodent diet were already available to the Sponsor.

Clinical observations
All animals were regularly handled and observed daily for obvious changes or signs of reaction to treatment.

Body weight
All adult rats were weighed on Days 1, 3, 6, 10, 14, 17 and 20 of gestation and on Days 0, 7, 14 and 21 post partum.

Food consumption and compound intake
For F0 females, food consumption was measured on a cage basis from 'weigh day' to 'weigh day' up to re-housing on Day 20 of pregnancy.
After weaning, food consumption of selected offspring was measured from nominal Week 4 to termination.

Water consumption
Water consumption was measured daily on a cage basis from allocation to treatment groups to Day 20 of pregnancy.

Reproduction parameters
Pregnancy rate
Pregnancy rate was determined as the percentage of surviving females that were pregnant.

Pregnancy and parturition
The duration of gestation was recorded. Parturition was observed wherever possible.

Litter data
As soon as possible after parturition the young were counted, individually identified, sexed, weighed and examined for external abnormalities. Pups were weighed on Days 4, 8, 12 and 21 post-partum keeping nest

disturbance to a minimum, all litters were examined daily for dead and/or abnormal young. After weaning, body weights of selected offspring were recorded on nominal weeks 4, 5 and 6. Dead young were subjected to an autopsy and sexed.

Physical development
Using body weight at Day 21 post partum as a basis for selection, ten male and ten female pups per group from an appropriate spread of litters were retained for a further three weeks on treated diet.

Sacrifice and pathology
Approximately one week after birth of litters, apparently non-pregnant females were sacrificed, subjected to post mortem examination and their uteri immersed in a 10% solution of ammonium sulphide to reveal evidence of implantation.

On, or shortly after Day 21 post partum, parents and excess pups were sacrificed and examined externally and internally for abnormalities. Sex of the pups was confirmed by gonadal inspection. The uterus of each female which gave birth was visually inspected for implantation sites and the number of sites was recorded. The parotid salivary gland of the parent females was preserved and examined histologically for any microscopic changes.

On, or shortly after Week 6, all surviving Fl animals were sacrificed and subjected to macroscopic post mortem examination.

Statistics
Group mean values, except for food and water, were calculated using only the values of animals rearing young to weaning. As F0 animals were group-housed to Day 20, food and water intake were based on all live animals regardless of their pregnancy status.
All derived values (e.g. means, percentage, ratios) were calculated within each litter and the group values derived as a mean of the individual litter values. Statistical analyses were not performed in view of the small group size.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS AND Achieved Test item intake
Analysis of dose formulations was not performed in this dose-range finding study.
F0 females
Group mean achieved intakes of glyphosate during gestation in groups 2 to 4 ranged from 236 - 311, 799 - 1010 and 2515 -2789 mg/kg bw/day, respectively. As expected, as the weight of the animals increased the actual intake of glyphosate (expressed as mg/kg bw/day) generally declined. The 3-fold interval in fixed ppm, between the groups remains established when expressed as mg/kg bw/day.

F1 offspring
Group achieved intakes of glyphosate in Groups 2 to 4, recorded during Weeks 5 and 6, ranged from 368 - 390, 1291 - 1335 and 3918 - 4453 mg/kg/day for males and 355 - 402, 1191 - 1271 and 3961 - 4397 mg/kg/day for females, respectively.

B. MORTALITY
F0 females
There were two mortalities. One female at 3000 ppm was sacrificed on Day 22 post partum due to poor condition. Post mortem examination did not reveal any reason for the apparent dystocia. Since no similar mortalities were seen at higher levels, this death is considered not to be attributable to treatment.
A second animal at 30000 ppm was found dead on Day 21 post partum (Day 43 of study). Post mortem examination or signs prior to sacrifice did not reveal the cause of death. It cannot be finally concluded whether this mortality was due to treatment with the test item or not.

F1 offspring
No mortalities were noted from weaning until scheduled sacrifice at 6 weeks of age.

C. CLINICAL OBSERVATIONS
F0 females
Clinical signs associated with the test item included soft faeces and yellow stained sawdust (considered to be caused by the urine) in both cages of animals at 10000 and 30000 ppm. Onset of these signs was earlier at 30000 ppm than at 10000 ppm (soft faeces occurred immediately after dietary administration commenced at 30000 ppm but not until the third week post partum at 10000 ppm, yellow staining of the sawdust occurred on Day 26 post coitum at 30000 ppm but not until Day 28 post coitum at 10000 ppm), with signs still apparent in both groups at termination. There were no clinical signs at 3000 ppm considered to be attributable to the test item.

F1 offspring
Soft faeces were observed for all animals at 30000 ppm from Week 4 through to sacrifice at Week 6. No other clinical signs were observed at this or lower dosages.

Table 5.6.1-60 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): F0 adult performance and clinical signs

Clinical sign	Control (0 ppm)	Low (3000 ppm)	Mid (10000 ppm)	High (30000 ppm)
Performance (no. of females)

Hair loss/scabbing on face	2	-	-	-

+ animal died Day 21 post partum, litter reared to weaning
++ animal subsequently sacrificed

D. BODY WEIGHT
F0 females
At 30000 ppm, the rate of body weight gain following the initiation of treatment was reduced to Day 14 of pregnancy; thereafter, the rate of body weight gain to Day 20 of pregnancy was similar to controls, however, absolute parity with controls at Day 20 was not achieved. At both 3000 and 10000 ppm the pattern of body weight gain during pregnancy was essentially similar to controls throughout, although by Day 14 of pregnancy, body weights were slightly lower than controls.
During the first week of lactation the pattern of body weight change in all groups was similar. Thereafter, slight differences in the pattern of change were apparent to weaning at 10000 and 30000 ppm in so much as more weight loss occurred than in the control group. There were no further effects at 3000 ppm.

F1 offspring
For pup body weight development please refer to section H. Litter data. From weaning to termination, males at 30000 ppm had a reduced rate of weight gain. At lower dosages, and at all dosages among females, the rate of weight gain was comparable with controls, however, differences inherent at weaning were still present by Week 6.

E. FOOD CONSUMPTION

F0 females

Apart from a slight reduction in food intake during the first three days of treatment at 30000 ppm, food intake of all treated groups was similar to concurrent controls throughout pregnancy.

Table 5.6.1-64 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): F0 females- food consumption during gestation (Group mean values)

Dietary concentration (ppm)	No. of animals	Gestation Days				
		3-5	6-9	10-13	14-16	17-19
Food consumption (g/rat/day)						
0 (Control)	10	23	26	27	28	30

10000	10	23	26	26	28	30
30000	10	21	25	27	28	30

F1 offspring

Food consumption at 30000 ppm was lower than controls during Weeks 5 and 6 (males only). There were no other effects considered attributable to treatment for males or females at any dosage. In addition, the food conversion ratio for males at 30000 ppm was slightly greater when compared to controls (Week 6 only), indicating a slightly lower efficiency of food utilisation into body weight gain. There were no other effects on food conversion ratios.

Table 5.6.1-65 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): F1 offspring - food consumption in Weeks 5 and 6 (Group mean values)

3000	10	100	123
10000	10	87	132
30000	10	80	132

F. WATER CONSUMPTION

At 30000 ppm, slight increases in water intake during gestation were apparent towards the end of pregnancy when compared with concurrent control values. At 3000 and 10000 ppm, no adverse effects on water consumption were observed.

Table 5.6.1-66Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): Water consumption during gestation (Group mean values)

Dietary concentration (ppm)	No. of animals	Gestation Days

30000	10	30	34	38	43	49

G. REPRODUCTIVE PARAMETERS

Pregnancy Rate and Duration of Gestation

The pregnancy rate was high, 90, 100 (incl. one ,dam that died on day 21 post partum), 100 and 90% in the control and the low, mid and high dose group, respectively. The duration of pregnancy was similar in all groups and not adversely affected by treatment with glyphosate.

Mating Performance, Fertility and Gestation

There were no treatment-related effects on mating performance, fertility and gestation length for both F0 and F1 generation animals.

+ sacrificed on Day 22 of pregnancy due to poor condition
++animal died Day 21 post partum, litter reared to weaning

H. LITTER DATA

Size and Viability

A total of 9, 9, 10 and 9 females reared litters to weaning in Groups 1 to 4, respectively (including one female found dead at weaning in Group 4).

The implantation rates in all treated groups were higher than the controls. Since pup losses, both pre-birth and from birth to weaning, were generally similar among the groups, litter size of all treated groups was, as a consequence, generally greater than controls throughout weaning. These findings are not, however, considered to be an adverse effect of treatment. Glyphosate did not selectively affect pups of one sex since, in all groups, sex ratios at birth and weaning were similar. The mean sex ratio did not reveal any treatment-related effect. In the mid dose group, a slightly higher percentage of male pups was noted both at birth and on day 21 post partum (60.5% compared to 46.7% in the control). In the absence of a dose-relationship this finding was considered incidental.

Growth and Development

At 30000 ppm, mean pup weight was reduced at birth and diverged further away from controls through to Day 21 when mean pup weight at this level was only 62% of the controls.

At 3000 and 10000 ppm, mean pup weight was initially (at birth and on day 4 post partum) similar to the controls but diverged below control values to an extent that on Day 21 post partum mean pup weight at 3000 and 10000 ppm was 9% and 13% lower than the corresponding control value. These differences, however, can probably be attributed to the pivotal association between increased litter size and mean pup weight and, at this stage, no conclusive treatment-related effects can be established.

Table 5.6.1-68 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): Litter data

	Control (0 ppm)	Low (3000 ppm)	Mid (10000 ppm)	High (30000 ppm)
Mean litter size				
at birth	13.2	14.2	14.1	14.6
at day 4 post partum	12.2	13.8	14.0	14.1
at day 8 post partum	12.1	13.7	13.6	13.8
at day 21 post partum	12.1	13.6	13.5	13.2
Mean pup weight (g)				
at birth	6.6	6.6	6.6	6.3
at day 4 post partum	10.1	9.9	9.9	9.3
at day 8 post partum	17.6	16.3	16.6	14.8

at birth	46.7	50.0	60.5	47.4
At day 21 post partum	48.0	50.2	61.5	47.5

I. PATHOLOGY

Necropsy

Watery and/or dark contents in the gastro-intestinal tract were observed in 0, 2, 7 and 8 animals in Groups 1 to 4 respectively. Distended and/or congested stomach was seen in 0, 2, 5 and 4 animals and distended caecum in 0, 0, 0 and 4 animals in Groups 1 to 4 respectively. These findings generally followed the trend noted in the clinical signs observed. Macroscopic changes to the salivary glands (enlarged/firm/congested/swollen) were observed in 0, 2, 6 and 8 animals respectively in Groups 1 to 4. There were no other macroscopic changes considered to be related to treatment.

Table 5.6.1-69 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): F0 females - necropsy findings

Clinical sign	Control (0 ppm)	Low (3000 ppm)	Mid (10000 ppm)	High (30000 ppm)
Necropsy findings				
Fur, ventral surface: yellow stained	-	-	1	-
Gasto-intestinal tract: contents watery and/or dark	-	2	7	8
Stomach: distended and/or congested	-	2	5	4
Stomach: contents watery	1	2	-	1
Caecum: distended	-	-	-	4
Caecum: contents watery	1	-	-	1
Salivary glands: enlarged /firm/congested/swollen	-	2	6	8
Lungs: multiple pale subpleural foci	1	3	3	1
Uterus: severe fluid distension	1*	-	-	-

* animal not pregnant

There were no toxicologically significant intergroup differences detected for the brain, spleen or thymus for offspring of either sex from either generation. Furthermore, there were no differences in uterus weights for treated females from either generation when compared to controls.

F1 offspring retained to 6 weeks of age

Post mortem examination revealed swollen/enlarged parotid salivary glands in 5/10 males and 2/10 females at 30000 ppm, and in l/10 males at 3000 ppm. Soft gastro-intestinal contents were noted in 7/10 males and 9/10 females at 30000 ppm; grey/blue contents of the jejunum were noted in 2/10 females at this dosage. Neither the incidence nor the type of other macroscopic changes were considered to be attributable to treatment.

Histopathology
F0 females
A dose-related incidence and degree of granular basophilic cytoplasm of acinar cells of the parotid glands was seen with 0, 2, 0 and 0 animals showing minimal effects, 0, 0, 2 and 0 animals showing moderate effects and 0, 0, 8 and 9 animals showing marked effects in Groups 1 to 4 respectively. This change was associated with hypertrophy of acinar cells with 0, 2, 2 and 0 animals with minimal hypertrophy and 0, 0, 8 and 9 animals in Groups 1 to 4 respectively with moderate hypertrophy of the acinar cells. Prominent mitoses were also seen in 2 animals at 30000 ppm, but not at lower treatment levels or the controls.

Table 5.6.1-70 Dietary range finding study of glyphosate in pregnant rats and their juvenile offspring ([redacted], 1991): F0 females - microscopic findings

Microscopic findings	Control (0 ppm)	Low (3000 ppm)	Mid (10000 ppm)	High (30000 ppm)
No. of animals examined	9	9	10	9
Parotid salivary glands				
Granular basophilic cytoplasm of acinar cells:				
Minimal	-	2	-	-
Moderate	-	-	2	-
Marked	-	-	8	9
Hypertrophy of acinar cells:				
Minimal	-	2	2	-
Moderate	-	-	8	9
Prominent mitosis in acinar cells	-	-	-	2

III. CONCLUSIONS

Study conclusion:
Assuming that effects seen in this preliminary study are representative of those that would occur in a comparable multiple generation study, a possible high level for the main study would appear to be less than 30000 ppm but greater than 10000 ppm, with a low level being less than 3000 ppm.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Dietary administration of glyphosate to pregnant dams at 30000 ppm resulted in a single death, clinical signs and body weight effects; at 10000 ppm resulted in clinical signs and body weight effects and at 3000 ppm slightly lower body weight gain by day 14 of pregnancy. Findings in F1 pups at 30000 ppm resulted in clinical signs, reduced food intake and body weight effects. While dose dependent changes were observed in the parotid glands of the parents and offspring these findings are considered to be an adaptive response due to oral irritation from the ingestion of glyphosate, an organic acid, in the diet and as such not considered to be toxicologically relevant. The doses selected for the definitive study were 0, 1000, 3000 and 10000 ppm.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/010**
Report author	[redacted]
Report year	1990
Report title	Two Generation Reproduction Feeding Study with Glyphosate in Sprague-Dawley Rats
Report No	[redacted]-10387
Document No	M-643937-01-1
Guidelines followed in study	Not stated, but in general accordance with OECD 416 (1983)
Deviations from current test guideline (OECD 416, 2001)	No data on food efficiency; no details on fertility indices, number of live births and post-implantation loss, number of pups with grossly visible abnormalities, no sperm analysis, no determination of oestrus cycle length, no determination of physical or sexual development landmarks, most parental animal organ weights missing, several offspring organ weights missing
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

30 Sprague-Dawley rats sex/dose group (F0 and F1a generation) were fed daily with glyphosate at concentrations of 2000, 10000 and 30000 ppm (corresponding to 132-140, 666-711, 1983-2230 mg/kg bw/day for males and 160-163, 777-804, 2322-2536 mg/kg bw/day for females (calculated from F0 and F1a adults)) through two generations for approximately 11 (F0-generation) and 14 weeks (F1a-generation), respectively. Animals of the F1a-generation were mated twice to produce the F2a and F2b-generations.
Pairing of animals within each dose group was undertaken on a 1:1 basis. At weaning of offspring from the F0 mating phase, groups of 30 male and 30 female offspring from each dose group were selected to form the F1a generation. The remaining surviving F0 females and unselected offspring were terminated at Day 21 post partum. Males were sacrificed after completion of mating phase. The offspring selected for the F1a generation were dosed for approximately 14 weeks and then paired within each dose group to produce the F2a and F2b litters. At weaning of the F2 litters all surviving adults and their offspring were killed, whereas F1 males were sacrificed after completion of mating phase.

Clinical observations for mortality and moribundity were performed twice daily, and detailed observations for signs of toxicity once weekly, when diets were prepared. Body weights were weekly determined for adults and on day 0, 4 (pre- and post-culling), 14 and 21 of lactation for offspring. Food consumption was determined weekly for adults and on days 0-7, 7-4 and 14-21 of gestation and lactation.
All animals at termination and which died, or were sacrificed moribund, were subjected to a gross necropsy. Histopathological evaluation of selected tissues was performed for control and highest dose level animals.

No significant changes concerning mortality, mating, fertility, organ weights, gross pathology and histopathology were observed. In the high dose group at 30000 ppm, soft stool in adults were observed in both sexes, being accompanied by reduced body weights of adult animals (about 8%) and pups (about 10%) when compared to controls. This effect was assumed to be treatment-related. Furthermore, decreased pup weights were observed when pups began supplementing their milk with the glyphosate-containing food. In

the 10000 ppm dose group, decreased pup body weights were observed, too, but the effect was less pronounced and occurred not in both sexes of all generations.
At the highest dose level of 30000 ppm a slightly, and statistically not significant, reduced average litter size was observed in the F0 and to a lesser degree in the F1 dams. A reduction was not noted when F1 animals were re-mated and treatment-relation was considered to be equivocal.

I. MATERIALS AND METHODS

A. Materials

Test Material:

Identification:	Glyphosate
Description:	White powder
Lot/Batch #:	XLI-203
Purity:	97.67%
Stability of test compound:	Not reported
Vehicle:	Plain diet
Test Animals:	
Species:	Albino Rat
Strain:	Sprague-Dawley
Source:	[redacted]
Age:	Approximately 7 weeks (F0 adults)
Sex:	Males and females
Weight at study start (F0):	Males: 165 – 207.6 g; Females: 135.6 – 162.7 g
Acclimation period:	No data
Diet/Food:	Purina Mills Certified RODENT CHOW No. 5002, ad libitum
Water:	St. Louis public water, ad libitum
Housing:	Housing for premating and gestation (day 0 through 13): individual suspended stainless steel cages over paper bedding; during mating females were housed in the male´s cages Housing for gestation and lactation (from day 14 of gestation through lactation): females housed in double wide cages with solid bottoms and wood shavings for bedding
Environmental conditions:	Temperature: 18 - 26°C Humidity: 40 - 70% 12 hours light/dark cycle

B. STUDY DESIGN

Animal assignment and treatment:

In a two-generation reproduction study, groups of 30 Sprague-Dawley rats per sex of the F0 generation received daily dietary doses of 2000, 10000 and 30000 ppm (corresponding to 132-140, 666-711, 1983-2230 mg/kg bw/day for males and 160-163, 777-804, 2322-2536 mg/kg bw/day for females (calculated from F0 and F1a adults)) glyphosate in the diet. After 11 weeks of treatment pairing of animals within each dose group was undertaken on a one male: one female basis in a male´s cage for 7 days, to produce the F1a litters. If there was no evidence of mating after 7 days (copulatory plug, or vaginal smear), the female was co-housed with a male having recorded copulatory activity for additional 7 days, or until copulatory evidence was found. For F0 and F1 generation, gestation day 0 was set on the day on which copulatory evidence was found and lactation day 0 the day on which delivery of pups was completed.

At weaning of offspring from the F0 mating phase, groups of 30 males and 30 females offspring from each dose group were selected to form the F1 generation and the mating procedure for F1a adults was conducted in the same way except modifications to exclude sibling matings. The remaining surviving F0 females and unselected offspring were terminated at Day 21 post partum. F0 males were killed at completion of mating phase. The offspring selected for the F1a generation were dosed for approximately 14 weeks and then mated to produce the F2a and F2b litters (a second mating of the F1 generation was performed due to reduced litter sizes in pups from F0 of the 30000 ppm dose group). At weaning of the F2 litters all surviving adults and their offspring were killed, whereas F1 males were sacrificed after completion of mating phase.

Diet preparation and analyses
Approximately each week (except in one week when diets were prepared twice the same week and not during the following week) a known amount of glyphosate was mixed with the diet for 10 minutes in a HOBART HCM-450 mixing machine to achieve a batch size of 18 kilograms at each dose level.
The stability and homogeneity of the test substance in the diet were determined by liquid chromatography of duplicate samples from top, middle and bottom of mixer from the lowest and highest dietary levels stored in an open container at ambient temperature for 6 and 14 days or when frozen in a closed container for 35 days.

Clinical observations
A detailed observation for signs of toxicity was performed once weekly for the adult animals and for the offspring on days of weight measurement.

Body weight
Adult male animals of the F0 and F1a generation were individually weighted once weekly. The same was done for the female animals until copulation was confirmed, then females were weighted on days 0, 7, 14, and 21 of gestation and lactation.
Offspring was weighted on days 0, 4 (pre- and post-culling), 14 and 21 of lactation (except F1a males approximately two weeks prior to sacrifice and F1a females for approximately three weeks prior to mating for the F2b generation).

Food consumption and compound intake
Food consumption was recorded weekly for F0 and F1a adult males, except during mating, and also weekly for adult F0 and F1a female animals until mating. After confirmed copulation, the maternal food consumption was monitored for days 0-7, 7-14 and 14-21 of gestation and lactation, but it was not determined for females approximately three weeks prior to mating for the F2b generation and generally not for female animals that did not became pregnant.
Food conversion efficiency was not calculated.

Water consumption
No data on water consumption was given in the report.

Pregnancy and parturition
Data on total paired females, females with confirmed copulation/total paired, pregnant/total paired, pregnant/ confirmed copulation was monitored as well as precoital (for pregnant animals) and gestational length in days. For males, the following items of interest were given: males with confirmed copulation/total paired, males impregnating females/total paired and males impregnating females/confirmed copulation.

Litter data
The following litter data were recorded: Litter size, dead pups/litter, mean pup weight (on day 0, 4 (pre-/post-cull), 14, 21) and survival (%).

Physical and sexual development
No details on physical and sexual development of the offspring was reported.

Sacrifice and pathology
All adult animals, which died or were sacrificed in moribund condition were subjected to a gross necropsy and selected tissues were sampled. Pups found dead or culled pups also underwent gross pathology, but no tissues were saved. No organ weights were determined.

All F1a weanlings, that were not selected for mating, F2a and F2b weanling pups as well as females which had littered on or after 21 of lactation were sacrificed as scheduled. Non-pregnant adult females were killed at least 5 days after last expected parturition date and adult males after completion of the mating phase.

External and internal cavities of the dead animals were opened and the organs were examined in place and then removed. Hollow organs were opened and examined. The following organs of F0 and F1a males and females from each dose group that were sacrificed at the end of the study sampled, were weighed: ovaries and testes with epididymides. When present, the following organs from the F0 and F1a adults (unscheduled deaths and scheduled sacrifice) were retained: kidneys, ovaries, prostate, seminal vesicle, skin/mammary gland, testes, epididymis, uterus/vagina and gross lesions (pituitary retained for F1a adults only). Tissues from the F1a weanlings were saved at the discretion of the necropsist. From the F2a and F2b weanlings, which where sacrificed at schedule, the kidneys of 1 pup per sex and litter were saved.

A histopathological examination was performed on all sampled tissues from all F0 and F1 control and high-dose animals, and on one F2b weanling/sex/litter (selected at random) as well as on all retained tissues from unscheduled adult deaths. For preparation, fixed tissues were washed, dehydrated, embedded in paraffin, sectioned, stained with haematoxylin and eosin and examinated under light microscopy.

Statistics
Dunnett´s multiple comparison test (two-tailed) was used to detect statistically significant differences in adult body weights and food consumption between treated animals and their respective control.

Terminal body weights, maternal body weights and food consumption during gestation and lactation, pup weights, precoital length, gestational length, litter size, dead pups/litter, pup survival, absolute organ weights and organ/body weight ratios were evaluated by decision-tree statistical analyses procedures which, depending on the results of tests for normality and homogeneity of variance [Bartlett's Test], were chosed either parametric [Dunnett's Test and Linear Regression] or nonparametric [Kruskal-Wallis, Donckheere's and/or Mann-Whitney Tests] routines to detect differences and analysed for trend.

The uncorrected Chi-Square test was used to examine fertility indices, e.g. females/males with confirmed copulation/total paired, pregnant/confirmed copulation (females) and males impregnating females/total paired as well as males impregnating females/confirmed copulation.

Fisher´s Exact test with Bonferroni Inequality Procedure was used for statistical analysis of microscopic lesions.

Other statistical routines used for some data included: Bartlett's Test to evaluate homogeneity of variances, Analysis of Variance to determine if the sample (group) means could be considered as an estimate of a common population, and Grubb's Test to detect outliers.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The analysis of the test substance stability conducted over the time span of the study indicated that the test material was stable in the diet and homogeneity was adequate for study use. The stability of the test material in the diet was demonstrated at the low and high dose level, stored in an open container at ambient temperature for 6 and 14 days, or when frozen in a closed container for 35 days.
Analysis for achieved concentrations, demonstrated that the test substance-levels in the prepared diet were

in the range of 95 to 96.7% of the nominal concentration.

B.TEST COMPOUND INTAKE
The group mean achieved dosages are summarised in the table below.

Table 5.6.1-71 Glyphosate technical: Two generation reproduction feeding study with glyphosate in Sprague-Dawley rats ([redacted], 1990): Group mean compound intake levels during pre-mating periods of F0 and F1

Dose group	Dietary concentration (ppm)	Mean daily test substance intake (mg/kg bw/day)*			
		F0		F1	
		Males	Females	Males	Females
control	0	0	0	0	0
low	2000	132	160	140	163
mid	10000	666	777	711	804
high	30000	1983	2322	2320	2536

* based on actual food intake and body weight data; values were calculated in the report

C. MORTALITY
There were no treatment-related mortalities.
One female of the F0 generation at 10000 ppm died early in the study. This animal was never mated and at necropsy changes in bladder in kidneys were observed. One male animal in each of the 2000 and 30000 ppm dose groups (F1 generation) died. Necropsy of these animals noted thymus and respiratory changes. One female animal of the F1 generation (2000 ppm) was sacrificed in extremis and another female (same generation, same dose group) died. Kidney changes and retained foetus; pups in uterus and stomach changes, respectively, were observed in these two females.
Concerning the offspring, dead pup counts at day 0 and survival of all F1a, F2a and F2b treated pups were not adversely affected when compared to the controls.

D. CLINICAL OBSERVATIONS
The only clinical signs that were related to the test substance were soft stool in the animals of the 30000 ppm dose group. Other clinical signs, such as red ocular discharge/laboured respiration/overgrown teeth/piloerection/abrasions/emaciated and dehydrated appearance/misuse of limbs/focal loss of hair/swollen feet, occurred sporadically and were not considered to be treatment-related.

E. BODY WEIGHT
At the highest exposure level of 30000 ppm, reduced body weights were observed in both sexes and in the F0 and F1 generation. In the F0 generation, body weights gains gradually decreased over time to approximately 8% less than controls prior to mating. F0/F1 weaning animals were lighter in weight than their corresponding controls and maintained that weight difference (approx. 10% less than control) until the end of the study
No test-substance related body weight effects were observed in the adult animals of the 2000 and 10000 ppm dose groups prior to mating.
During gestation and lactation, maternal body weights in the highest dose group tended to remain lower than in controls, but the animals showed a rather greater body weight gain than the controls during gestation and lactation so that by the end of lactation, body weights were approximately the same as those of the controls.
Terminal body weights were significantly decreased for both sexes at the highest exposure level.

F. FOOD CONSUMPTION

Overall, food intake was not notably affected during the study.
All animals of the 30000 ppm dose group consumed about 1 to 2 grams/day less than controls. This effect was most pronounced in the first week of exposure and also observed in the F0 dams. Subsequent dams (F1 first and second matings) tended to eat similar or larger amounts of the diet than controls.
No effects on food consumption were observed in the animals of the 2000 and 10000 ppm dose groups.

G. REPRODUCTIVE PARAMETERS

Mating Performance, Fertility, Gestation and Lactation

No effects on mating and fertility rates were observed in the F0 and F1 dams when compared to controls and no effects were observed on precoital length or length of gestation at any treatment level.

Table 5.6.1-75Glyphosate technical: Two generation reproduction feeding study with glyphosate in Sprague-Dawley rats ([redacted], 1990): Mating, fertility and gestation parameters (F0).

H. LITTER DATA

Size and Viability

Day 0 dead pup counts among treated groups were comparable to the control group for all three litters of pups (F1a, F2a and F2b generation).

A slight reduction in the average litter size was observed in the F0 dams of the 30000 ppm dose group. This effect was less pronounced in animals after the first F1 mating. Although the difference was not statistically significant and not accompanied by an increase in dead pups/litter, a treatment-related effect could not be excluded. Therefore a second mating of the F1a adults was performed. In the resulting F2b generation, no dose-related decrease in litter size was observed.

Growth and Development

Birth weights and initial growth rate for pups from the treated dams compared well to the ones of the control, except the pups of the 30000 ppm dose group had reduced body weight gains on day 21 of lactation (more than 10% difference to controls). The effect was present earlier in the F1 matings (day 14). This effect was explained by the titrated uptake of the test substance-containing diet at the end of lactation. In the mid dose group, slight and transient decreases in pups body weight gains were observed compared with the control. These effects were not evident in both sexes from all generations and therefore regarded of questionable toxicological significance. Pup survival during the postnatal period was not affected.

			0-4	4-14	4-21
		SD	11.67	0.00	0.00

Clinical signs
No clinical signs were observed in the offspring of treated animals.

I. PATHOLOGY
Necropsy
There were no toxicologically significant macroscopic gross lesions attributed to the test chemical administration.

Organ weights
There were no statistically significant organ weight changes, except a slight increase in testes to body weight ratios in F1a adults of the 30000 ppm dose group. This effect was attributed to their lower terminal body weight.

Histopathology
No treatment-related changes were detected.

III. CONCLUSIONS

Study conclusion:
The oral administration of glyphosate to rats via diet at a dose levels of 2000, 10000 and 30000 ppm for two successive generations resulted in possible treatment-related changes at the maximum dose of 30000 ppm. A high incidence of soft stools in adults was accompanied by consistent reduction of body weight gains of adults and pups at this dose level. Decreases in body weight gains of the pups obviously occurred at the end of lactation, with the beginning of consuming the test substance-containing diet. Furthermore, slightly but not statistically significant reduced average litter size was noted in F0 dams of the 30000 ppm dose group at first mating. This effect was not observed in the litters of the second mating. Therefore the NOAEL was considered to be 10000 ppm for adult toxicity for both the F0 and F1 generations (corresponding to 666-711 mg/kg bw/day for males and 777-804 mg/kg bw/day for females).

The NOAEL for reproductive toxicity, for both generations and offspring was considered to be 30000 ppm. The NOAEL for developmental toxicity, for both generations and offspring was considered to be 10000 ppm.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The NOAEL was considered to be 10000 ppm for adult toxicity for both the F0 and F1 generations (corresponding to 666-711 mg/kg bw/day for males and 777-804 mg/kg bw/day for females). The NOAEL for reproductive toxicity, for both generations and offspring was considered to be 30000 ppm. The NOAEL for developmental toxicity, for both generations and offspring was considered to be 10000 ppm.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/011**
Report author	[redacted]
Report year	1988
Report title	Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, on fertility and general reproductive performance (Segment I)
Report No	None stated
Document No	42-90619
Guidelines followed in study	No guideline cited in the report and not in accordance with OECD 415 (1983)
Deviations from current test guideline (OECD 415, 2019)	Test substance purity not given; group size too small; missing endpoints: body weights or food consumption for parental males, body weights for females during premating period and until Day14 of gestation, estrous cycle monitoring, pre-coital interval, duration of gestation, sperm analysis, organ weights, histopathology, monitoring of physical and sexual offspring development, dose levels tested too low
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	No, GLP was not compulsory when the study was performed
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Three groups of rats were administered glyphosate technical orally, by gavage, at dose levels of 0, 5 and 10 mg/kg bw/day. Controls received the vehicle (corn oil), only. Male rats were treated for 60 days before mating while treatment of female rats started 14 days before mating and was continued during gestation and lactation. The animals were mated in a sex ratio of 1 male : 3 females. Male rats were sacrificed after mating and testes were examined hitsopathologically. Half of the females were sacrificed on Day 13 of gestation and the uteri were examined for living foetuses, early and late deaths and the ovaries for the number of corpora lutea. The remaining females were allowed to litter and rear their offspring until day 21 post partum. Litter size, growth rate and survival rates of pups were recorded. Body weight and food consumption of females were recorded periodically. Under the condition of this study, glyphosate technical did not produce any toxic effects on fertility and general reproduction performance in rats.

I. MATERIALS AND METHODS

A. Materials

Test Material:

Identification:	Glyphosate technical
Description:	Not reported
Batch #:	Not reported
Purity:	Not reported

Expiry date:	Not reported
Stability of test compound:	Not reported
Vehicle:	Corn oil
Test Animals:	
Species:	Rat
Strain:	Wistar rats
Source:	Not reported
Number of animals:	120 (30 males and 90 females)
Age at start of treatment:	Not reported
Sex:	Males and females
Initial body weights:	70-130 g (no further information)
Acclimation period:	Not reported
Diet/Food:	Pelleted food from Lipton India
Water:	Not reported
Housing:	Polypropylene rat cages with paddy as bedding; single housing during pregnancy, dams were housed with their litters until weaning
Environmental conditions:	Temperature: 19-25°C Humidity: 50-70% Air changes: Not reported 12 hours light/dark cycle

B. STUDY DESIGN
In life dates: not reported

Animal assignment and treatment:
In this reproduction toxicity study groups of 10 male and 30 female Wistar rats received daily doses of 0, 5 and 10 mg/kg bw glyphosate technical per gastric gavage. After approximately 60 days of treatment for males and 14 days of treatment for females pairing of animals within each dose group was undertaken on a one male: three female basis. Males were sacrificed after mating. Pregnant females were either sacrificed on Day 13 of gestation or were allowed to litter and raise their offspring until weaning on Day 21 post partum.

Clinical observations
All animals were observed daily for any signs of toxicity.

Body weight
Parental female body weights were recorded periodically during gestation and lactation.

Food consumption
Parental female food consumption was recorded periodically during gestation and lactation.

Mating procedure and vaginal smears
After the scheduled period of treatment (approx. 60 days for males and 14 days for females), pairing of animals within each dose group was undertaken on a one male: three female basis. Succesful mating (Day 0 of pregnancy) was confirmed by presence of vaginal plugs.

Pre-coital interval

Not reported.

Duration of gestation
Not reported.

Reproduction parameters
Half of the females were sacrificed on Day 13 of gestation and the uteri were examined for living foetuses, early and late deaths and the ovaries for the number of corpora lutea. The remaining females were allowed to litter and rear their offspring until day 21 post partum.

Litter data
Litter size, growth rate and survival rates of pups were recorded.

Assessment of development and reproductive performance of progeny
Not reported.

Sacrifice and pathology
Males were sacrificed after mating. Pregnant females were either sacrificed on Day 13 of gestation or at weaning on Day 21 post partum.

Statistics
Not reported.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
Not reported.

B. MORTALITY
There were no mortalities in parental animals.

C. CLINICAL OBSERVATIONS
No clinical signs of toxicity were noted throughout the study

D. BODY WEIGHT
There were no effects on body weights in female rats up to and including 10 mg glyphosate/kg bw/day.

Table 5.6.1-80 Glyphosate technical: Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, on fertility and general reproductive performance (Segment I) ([redacted], 1988a): Body weights (group mean) of females

Body weight (g) ± SE	Dose level (mg/kg bw/day)		
Day	0 (control)	5	10
Post coitum			
15	210.5 ± 5.65	194.2 ±4.47	200.7 ± 4.06
20	225.4 ± 5.07	211.3 ±4.81	217.2 ± 4.17
Post partum			
0	172.6 ± 5.33	174.7 ± 5.10	166.2 ± 4.25
6	170.6 ± 4.90	179.2 ± 5.10	168.5 ± 4.31
12	172.9 ± 5.00	179.3 ± 4.99	171.2 ± 4.02
18	174.8 ± 4.80	180.3 ± 4.62	171.5 ± 3.87

21	176.5 ± 5.16	180.7 ± 4.51	172.2 ± 3.77

E. FOOD CONSUMPTION

There were no effects on food consumption in female rats up to and including 10 mg glyphosate/kg bw/day.

F. REPRODUCTIVE PARAMETERS

When the animals were sacrificed on Day 13 of gestation, the number of corpora lutea, total implantations, early and late deaths and living implantations were similar in test item-treated and control animals.
When allowed to give birth, the litter size, growth and survival rate of test item-treated and control animals were similar.

Table 5.6.1-81 Glyphosate technical: Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, on fertility and general reproductive performance (Segment I) ([redacted], 1988a): Reproduction data Day 13 of gestation

Parameter	Dose level (mg/kg bw/day)		
	0 (control)	5	10
No. of dams in group	13	12	12
Total No. of corpora lutea	113	107	121
Total No. of implantations	108	104	117
Total No. of early deaths	3	1	1
Total No. of late deaths	2	1	2
Total No. of living foetuses	103	102	114

G. LITTER DATA

Number of pups delivered
There was no relevant difference in litter size between the three groups.

Viability index

A small number of dead pups was noted between post partum days 0 and 4 in all dose groups including the control. The incidence of dead pups was not affected by treatment with the test item. No pup mortalitiy was noted in any group from Day 4 post partum until weaning on Day 21 post partum.

Table 5.6.1-82 Glyphosate technical: Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, on fertility and general reproductive performance (Segment I) ([redacted], 1988a): Litter size and survival rates (group means)

Parameter	Dose level (mg/kg bw/day)		
	0 (control)	5	10
Mean litter size ± SE	8.92 ± 0.73	8.92 ± 0.54	8.58 ± 0.66
Survival rates (%)			
Day 0	100.0 ± 0.00	100.0 ± 0.00	100.0 ± 0.00
Day 4	97.3 ±1.51	98.4 ± 1.03	99.2 ± 0.76
Day 14	97.3 ± 1.51	98.4 ± 1.03	99.2 ± 0.76
Day 21	97.3 ± 1.51	98.4 ± 1.03	99.2 ± 0.76

Body weights

Pup weights generally developed similar in the test item-treated groups and the control group.

Table 5.6.1-83Glyphosate technical: Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, on fertility and general reproductive performance (Segment I) ([redacted], 1988a): Pup body weights (group means)

Body weight (g) ± SE	Dose level (mg/kg bw/day)		
Day	0 (control)	5	10
Post partum			
0	5.77 ± 0.10	5.42 ± 0.14	5.70 ± 0.19
4	10.09 ± 0.24	9.41 ± 0.28	9.97 ± 0.41
14	18.87 ± 0.59	17.96 ± 0.48	19.76 ± 1.02
21	29.56 ± 0.69	29.25 ± 0.55	30.37 ± 0.62

H. Histopathology
No histopatholical findings were noted in the testes of any animal on study.

Study conclusion:
Glyphosate technical supplied by Excel Ltd., Bombay, did not produce any toxic effect on fertility and general reproductive performance up to the high dose of 10 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Under the conditions of this study, glyphosate technical did not produce any effects on fertility and general reproductive performance up to the high dose of 10 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/012**

2. Full summary
Glyphosate technical was given via the diet at dose levels of 0, 75, 150 or 300 ppm to Wistar rats over three generations. In the F0 generation, the groups consisted of 8 male and 16 female animals from which similar groups were produced by selective mating for the F1, F2 and F3 generations. Two litters per generation were delivered. The rats were observed for changes in body weight and food consumption, pregnancy rate, litter size, number of live and stillborn pups and any abnormalities. Testes of F0 males and selected organs and tissues of parental animals in the F1 and F2 generations were examined histopathologically.
There were no adverse effects of treatment observed in any of the parameters investigated.

I. MATERIALS AND METHODS

B. STUDY DESIGN
In life dates: not reported

Animal assignment and treatment:
In this three-generation reproduction study groups of 8 male and 16 female Wistar rats of the F0 generation received daily dietary doses of 0, 75, 150 and 300 ppm glyphosate technical in diet. Animals were kept on this diet until weaning of the F3b generation.
After 60 days and 14 days of treatment for males and females, respectively, pairing of animals mating within each dose group was undertaken on a one male: two female basis, to produce the F1 litters. Pregnant females were allowed to deliver and rear their litters (F1a) until weaning on Day 21 post partum. After a rest of 10-15 days parental females were mated again with the same male in a similar manner to deliver and rear the F1b litter. Eight males and 16 females were chosen from the F1b offspring as parents for the F2 generation. The mating of siblings was avoided. The procedure described above was repeated to produce the F3 offspring. Standardisation of litter size: on day 4 post partum litter size was adjusted to 4 males and 4 females, where possible.

Diet preparation and analyses
The test item was mixed with food to achieve concentrations of 75, 150 and 300 ppm. The control group received plain food.

Clinical observations
A gross general observation was made for each animal once a day.

Body weight
Body weights of F0 animals, and for F1 and F2 animals selected for rearing were recorded weekly. Body weights of the F0 animals were recorded during mating and weaning period only. Offspring not selected to produce a next generation was weighed on days 0, 4, 14 and 21 post partum. F1 offspring (males) selected to produce the F2 generation were weighed up to and during mating. F2 offspring (males) selected to produce the F3 generation were weighed up to and during mating for the F3b generation. F1 offspring (females) selected to produce the F2 generation were weighed up to weaning of the F2b generation. F2 offspring (females) selected to produce the F3 generation were weighed up to weaning of the F3b generation.

Food consumption and compound intake
The amount of food consumed was determined once weekly for parental animals of all three generations. However, reported values do not include data for all animals in every group.

Mating procedure and vaginal smears
After the scheduled period of treatment (60 days for males and 14 days for females), females were paired on a one- to-two basis with males from the same treatrnent group for a maximum of one week.

Pre-coital interval
Not reported.

Duration of gestation
Not reported.

Reproduction parameters

For each generation and mating phase, the number of dams mated, pregnant and littering were recorded.

Litter data
For each generation and mating phase, the number of live and dead pups per dam were recorded.

Assessment of development and reproductive performance of progeny
Not reported.

Sacrifice and pathology
All F1a offspring was sacrificed after weaning. F0 males were sacrificed after mating for the F1b generation. Necropsy was performed and testes were preserved for histopathological examination.
F1b offspring not selected for rearing were sacrificed after weaning. All F2a offspring were sacrificed after weaning. F1b parental males were sacrificed 1 week after mating for the F2b generation. Necropsy was performed and a range of organs (see below) including testes were preserved for histopathological examination. F2b offspring not selected for rearing was sacrificed after weaning. F1b and F2b parental females were sacrificed after weaning of the F2b and F3b generation, respectively. Necropsy was performed and the following tissues were preserved for histopathological examination: adrenals, aorta, brain, colon, duodenum, eyes, heart, ileum, kidney, liver, lung, oesophagus, ovaries, pancreas, pituitary, seminal vesicles, spleen, stomach, testes, thyroid, urinary bladder, uterus and salivary glands. All offspring of the F3a generation was sacrificed after weaning. F2b parental males were sacrificed 1 week after mating for the F3b generation. Necropsy was performed and the tissue listed above were preserved for histopathological examination. All F3b offspring was sacrificed after weaning.

Statistics
Not reported.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE CONCENTRATIONS IN THE DIET
Not reported.

B. TEST COMPOUND INTAKE
Not reported.

C. MORTALITY
There were no mortalities in animals after weaning. A low incidence of pup mortality was noted in all groups without any test item effects.

D. CLINICAL OBSERVATIONS
No clinical signs of toxicity were noted throughout the study.

E. BODY WEIGHT
There was no substantial difference in the body weight gain of test item-treated animals at any dose level compared to the respective control animals.

F. FOOD CONSUMPTION
No significant differences in food consumption were observed between test item-treated and control animals in any of the three generations.

G. REPRODUCTIVE PARAMETERS
Pregnancy rate
The number of pregnant females was not significantly different between test item-treated and control groups.

H. LITTER DATA

Number of pups delivered

Litter size varied from 7 to 10 in all four groups in all three generations and there was no significant difference in litter size.

Viability index

The number of dead pups per litter varied from 0 to 2 and the rate was less than 3.3 pups per litter. There was no significant difference in the number of dead pups in the test item-treated groups when compared to their respective control group.

Body weights

Pup weights generally developed similar in the test item-treated groups and the respective control groups.

I. Histopathology

Histopathological examination of various tissues from animals at all dose levels did not reveal any structural changes attributable to treatment with the test item.

Study conclusion:

There were no adverse effects of treatment observed in any of the parameters investigated. Thus, a dose level of 300 ppm was considered the NOAEL for both parental and reproduction toxicity. Using the usual conversion factor of 20, this concentration would correspond to an approximate daily intake of 15 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

supportiveThere were no adverse effects of treatment observed in any of the parameters investigated in this study, thus a dose level of 300 ppm was considered the NOEL for both parental and reproduction toxicity. Using the usual conversion factor of 20, this concentration would correspond to an approximate daily intake of 15 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.1/013**
Report author	[redacted]
Report year	1985

Report title	Three-generation reproduction study in rats with the oral administration of glyphosate
Report No	Not reported
Document No	Not reported
Guidelines followed in study	None (pre-guideline)
GLP	No (GLP was not compulsory at the time the study was performed)
Previous evaluation	Not accepted in RAR (2015)
Short description of study design and observations:	Glyphosate (purity not indicated) was fed to Wistar rats for three consecutive generations at dietary levels of 0, 200, 1000 and 5000 ppm. Rats were administered the test substance in their diet for a 12–week period before first mating. Males and females were mated in a sex ratio of 1:1. In the F1 and F2 generations, there were two matings. In contrast, three litters were produced in the F3 generation. The number of paired animals varied between the generations. In the Fa generation, 6 males and 6 females were used. The respective numbers were 12 and 24 for the F1B and F2B generations. These animals were sacrificed on day 28 after parturition. Glyphosate administration was continued until this day. In the F3C generation, 10 animals per sex and dose group were selected by randomisation and examined following an 8–week dosing period and a subsequent 4–week recovery phase. All the rats were daily observed for signs of toxicity. Body weight and food consumption were determined regularly. Litter parameters were recorded. Prior to sacrifice of adult rats, blood was taken for haematological and clinical chemistry investigations. Following sacrifice, the animals were necropsied and organ weights were determined. A limited number of rats (3 or 5 per dose group and generation) was subjected to histopathology.
Short description of results:	No adverse effects of treatment were observed neither in adult rats nor in the pups in any of the groups up to the highest dose of 5000 ppm. There were occasional differences in the parameters indicative of reproductive performance among the groups, however, no consistent and dose-related trend throughout the generations was found.
Reasons for why the study is not considered relevant/reliable or not considered as key study:	Study was deleted due to major deficiencies and/or because dose levels were much too low
Reasons why the study report is not available for submission	The notifier has no access to this study report. Since the study was part of the earlier data package available to the former RMS of the active substance glyphosate, the AGG would have to send a "request for administrative assistance (Art. 39 of Regulation (EC) No. 1107/2009) to the BVL.

2. Full summary

Rats were administered glyphosate oral via diet continuously for three successive generations. Each generation (F0, F1 and F2) consisted of 12 male and 24 female Charles River CD® rats. Dietary concentrations were adjusted weekly during growth, and between mating rest periods, to achieve dose levels of 3, 10, and 30 mg/kg bw/day. A concurrent control group (plain diet) was included in the study. Each parent generation was mated to produce two litters. Offspring from the second litters of the F0 and F1 parents (F1b and F2b litters, respectively) were selected to be parents for subsequent generations. Offspring not included in the selection procedure and offspring from the first litter intervals of each generation (F1a, F2a, and F3a) were sacrificed at weaning and given a gross post mortem examination. Pathological and histopathological examinations were conducted from control and high-dose parent generations (F0, F1 and F2) and from control and high dose F3b offspring at weaning (10/sex/group). Parameters evaluated for each generation included: mortality, body weight, food consumption, clinical observation, maternal body weights (gestation/lactation), reproduction-fertility indices (mating, pregnancy and fertility indices), litter data at parturition and organ weight data. Offspring from each litter interval were evaluated during a 21–day lactation period for growth, survival, sex distribution data and gross post mortem observations including organ weight data (F3b offspring only).

No treatment-related effect was evident in adult mortality data, body weight and food consumption data (growth and rest periods), and clinical observation data throughout the study (F0, F1 and F2 generation). Considerable variability was seen in the mating-fertility indices during this study in both, the control and treated groups, in particular during the F1 and F2 generations. In the control group, mating indices were low for both mating intervals of the F1 generation and in the F2 generation these indices were higher than normally encountered. Similar fluctuations were seen in mating indices for some of the treated groups during these same intervals. Throughout the study no consistent effect was seen in mating indices, fertility indices (male) or pregnancy rate data to suggest an adverse effect of treatment.

No adverse effects of treatment were evident in maternal weight data, gestation length, parturition data (number of live/dead pups at birth) or litter survival indices throughout the study. Concerning the offspring, no treatment-related effects were indicated in sex distribution data, body weights, survival or gross post mortem findings. Likewise, no effect of treatment was evident in mean organ weight data (absolute and relative to body or brain weight) for randomly selected Day 21 F3b offspring.

No adverse effect of treatment was evident in organ weight data for the F0, F1 generations and F2 adult males. In the F2 treated females, a non-dose related, albeit statistically significant, decrease in mean liver/body weight ratio was evident; liver/brain weight ratios for these females showed a similar reduction; however, these differences from control were not statistically significant.

Gross post mortem evaluations of the adult generations and histological evaluations of tissues from randomly selected F0, F1 and F2 high-dose animals and F3b high-dose offspring did not indicate a

treatment-related effect.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate
Description:	Fine white powder
Lot #:	XHJ-64
Purity:	considered 100% active ingredient for dosing preparations
Stability of test compound:	Not reported
Vehicle:	Plain diet
Test Animals:	
Species:	Rat
Strain:	CD® (Sprague-Dawley derived)
Source:	[redacted]
Age at treatment initiation:	43 days
Sex:	Males and females
Mean weight at initiation of dosing:	Males: 139.9 - 144.3 g; females: 118.0 - 119.2 g
Acclimation period:	7 days
Diet/Food:	Standard laboratory diet (Purina Lab Chow® 5001), ad libitum
Water:	Automated watering system (Elizabethtown Water Company), ad libitum
Housing:	Individually (except during mating and lactation), in elevated stainless steel wire mesh cages; nesting material: Litter Kleen® hardwood shavings added to cages on Day 19 of gestation and changed when wet or soiled through Day 14 of lactation
Environmental conditions:	12 hours light/dark cycle No details on temperature and humidity reported

B. STUDY DESIGN

In life dates: 1978-06-14 - 1980-04-09

Animal assignment and treatment:
In a three generation reproduction study groups of 12 male and 24 female CD rats received beginning 63 days prior to mating of the F0 generation daily dietary doses of 0, 3, 10 and 30 mg glyphosate/kg bw in diet. Diet samples were taken at four week intervals for analysis of achieved test substance concentrations.

Mating: One male and two females of equivalent dose levels were caged together nightly until a sign of mating (sperm and/or copulation plug in the vagina) was observed or until 15 days had elapsed with no evidence of mating. The day on which evidence of mating was observed was defined as Day 0 of gestation.

In this study, the first litters (F1a, F2a and F3a) from each mating were raised to weaning and discarded. Rats produced by the second matings (F1b and F2b) were selected to become parents of succeeding generations or to be subjected to complete gross necropsy (F3b).

Table 5.6.1-87 Glyphosate technical: Dietary Two Generation Reproduction Study in the Rat ([redacted], 1981): Study design

Group	Dose level (mg/kg bw/day)	No. of adults initially assigned to mate F0, F1, F2		No. of matings per generation F0, F1, F2	Gross post mortem examination	Histopathology of F0, F1 and F2 parents, F3b weanlings	
		Males	Females			Male	Female
1 Control (plain diet)	0	12	24	2	All	10	10
2	3	12	24	2		none	none
3	10	12	24	2		none	none
4	30	12	24	2		10	10

Diet preparation and analyses
Diets were prepared weekly during the study and were adjusted on the basis of body weight and food consumption.

Clinical observations
A check for clinical signs of toxicity and mortality was made twice daily. A detailed physical examination was performed on adult generations at weekly intervals throughout the study.

Body weight
Body weights of all animals were determined weekly during growth and rest periods of all generations. Pregnant females were weighed on Days 0, 6, 15 and 20 of gestation and lactating females were weighed on Days 0, 4, 14 and 21 of lactation.

Food consumption and compound intake
Food consumption was recorded weekly during growth and rest periods of all generations. Test substance intake was calculated from individual body weight and food consumption data and reported as a group mean value for weekly intervals during the growth and rest periods of all generations.

Reproduction parameters
The day on which evidence of mating was observed was designated as Day 0 of gestation; the day of delivery was designated as Day 0 of lactation.
Mating indices, pregnancy rates, length of gestation and male fertility indices were recorded.

Litter data
Pups of all generations were examined daily for general appearance and mortality. On Days 0, 4, 14, and 21 they were counted to record the number of live and dead pups. Body weights were determined on Days 0, 4, 14, and 21 as a litter and on Day 21 individually.
Total number of live and dead pups, and the number of males and females per litter were determined on Day 0 of lactation. The sex ratio was calculated for each group on Days 0 and 21 of lactation. Viability indices, were determined for each litter on Lactation Days 0, 4 and 21.

Sacrifice and pathology
Animals of all generations that died, were found dead or were killed moribund during the study period were necropsied as soon as possible. All adult males and females were sacrificed after pup selection of the last Fb litter (F0, F1) and after last F3b litter weaned (F2) by lethal exposure to ether. Pups that were found dead or stillborn pups were weighed and given a gross post mortem examination including internal sex determination, presence of milk in stomach. F1a, F2a, F3a and F3b animals were sacrificed at weaning,

given a gross post mortem examination and abnormal tissues were saved. F1b and F2b animals which were not selected as future parents were sacrificed after ensuing selection of parental animals, given a gross post mortem examination and abnormal tissues were saved.

The following organs and tissues were preserved from all parents (F0, F1, F2) and from 10/sex/group of the F3b weanlings: adrenals, aorta, bone and bone marrow (sternal), brain, colon, duodenum, eyes with optic nerve and Harderian gland, gonads (ovaries and testes), heart, ileum, kidney (2), liver (2 sections), lung with main stem bronchi, lymph nodes (mesenteric), mammary gland (right inguinal), pancreas, pituitary, salivary gland, skeletal muscle (biceps femoris with right sciatic nerve), skin, spinal cord, spleen, stomach, thyroid/parathyroid, urinary bladder, uterus/prostate, gross lesions, tissue masses, thymus.
Microscopic examination of histological sections of these tissues were done for 10 male and 10 female animals from control and high-dose groups of F0, F1 and F2 parents and of F3b offspring.

The following organs were weighed from all parents sacrificed after weaning of the second litters and from eighty F3b weanlings (10 males and 10 females per group): adrenals, gonads, kidneys, brain, spleen, liver, heart and pituitary.

All pups of the second litter of the F2 parents (F3b) were necropsied at weaning and specified tissues were preserved for selected animals in each group.

F
Body weights, body weight gain, maternal body weights, food consumption, number of offspring, offspring body weights, terminal body weights and organ weight data (absolute and relative), offspring survival, litter survival, pup viability index at birth, mating indices, pregnancy rates and male fertility indices data were compared to the control. Statistically significant differences were evaluated using several methods including Dunnett's test, ANOVA, Barlett's test, Kruskal-Wallis test and Fisher Exact Test.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
Not reported.

B. MORTALITY
F0 adults (2 dead females in mid-dose group)
In the F0 generation, no unscheduled mortality occurred in the control, low- or high-dose groups. One female of the mid-dose group died during on Lactation Day 20 of first litter having 13 live pups at time of death. A second female of the mid-dose group died on Lactation Day 7 of second litter; this female delivered eight pups - seven live and one dead - and all pups were dead at time of death. No mid-dose F0 male died.

F1 adults (1 dead female in mid-dose group, 1 dead female in high-dose group)
In the F1 generation, no unscheduled mortality occurred in the control or low-dose groups. In the mid dose group one female was killed in a moribund condition during the post-mating period for the second litter. This female had mated during the first mating but did not deliver a litter; during the second mating this female had not mated. No other mortality occurred in the mid-dose group. In the high dose group one female died due to an accident (animal was caught in the feeder jar). A second high-dose female died on Day 21 of gestation for the second litter; the uterus of this female contained 15 term foetuses. No other mortality occurred in the high-dose group.

F2 adults (1 dead female in low-dose group, 1 dead male in mid-dose group)
In the F2 generation, no unscheduled mortality occurred in the control or high-dose groups. In the low-dose group one female died during the F3a lactation period. This female delivered a litter containing only dead pups (13 pups) and died the day after parturition. No other mortality occurred in the low-dose group. In the mid-dose group one male was killed in a moribund condition during the period between mating of the first

and second litters. This male had mated and impregnated both females during the first mating period. No other mortality occurred in the mid dose group.

C. CLINICAL OBSERVATIONS
Clinical observation data were similar between the control and treated groups for each generation interval throughout the study. No adverse treatment effects were indicated.

D. BODY WEIGHT
Mean body weight data during the growth and rest periods were comparable between the control and treated groups for each generation, throughout the study. Likewise, mean weight gain during the growth periods were comparable between these same groups for both sexes throughout all generations. No treatment effect on body weight data during the growth and rest periods was evident.

Maternal body weights
Mean body weight data during the gestation and lactation intervals and mean weight change during these same periods were comparable between the control and treated group for each pregnancy interval from each generation throughout the study. No treatment effect was indicated in gestation - lactation body weight data throughout the study.

Offspring body weights
Mean pup body weight data during each litter interval for each generation were comparable between the control and treated groups. No adverse effects of treatment on pup weight data was evident.

Adult animals (F0, F1 and F2)
Mean terminal body weight data were comparable between the control and treated groups for both males and females throughout the study.

E. FOOD CONSUMPTION AND TEST COMPOUND INTAKE
Mean food consumption data were considered comparable between the control and treated groups (both sexes) during the growth and rest periods for each generation, throughout the study. No adverse effect of treatment on food consumption was evident throughout the study. Mean weekly test substance intake values ranged from 2.8 to 3.3 mg/kg bw/day for the low-dose group, from 9.5 to 11.2 mg/kg bw/day for the mid-dose group and from 27.7 to 33.1 mg/kg bw/day for the high dose group for all generations including both genders.

F. REPRODUCTIVE PARAMETERS
Male and female mating indices and male fertility indices during both mating intervals of the F0 generation were considered comparable between the control and treated groups. During the second mating interval of the F0, pregnancy rates were lower than control in each of the treated groups; however, no indication of a dose-relationship was evident as the lowest pregnancy rate was seen in the mid-dose group. This reduction in pregnancy rate for the mid-dose group was not statistically significant. In the absence of a dose-response relationship the reduction in pregnancy rate during this mating interval (F1b) in the treated groups was not considered treatment-related.

In the F1 generation, mating indices (males and females) for both litter intervals were comparable between the control and treated groups. It is note-worthy that for both mating intervals of this generation, mating indices for control and some treated groups were lower than normally encountered in multi-generation studies. The reason for the poorer mating performance in this generation was unclear but no treatment effect was indicated since mating indices were lowest in the control group. Pregnancy and male fertility indices for the first mating interval of the F1 were comparable between the control and treated groups. During the second litter interval, pregnancy rates were lower than those seen for the first interval in control and treated groups. The lowest pregnancy rate was seen in the high-dose group; however, this difference from the control value was not statistically significant. Pregnancy rates for the low- and mid-dose groups, during the second mating interval, were considered comparable to control. Male fertility indices for this same mating

interval were considered comparable between the control and treated groups.

In the F2 generation mating indices for the treated groups were lower than control for each mating interval. During the first mating interval of the F2 generation, the female mating indices were lower than control in each of the treated groups; however, only in the high-dose group was this difference from control statistically significant. The female mating index for the control group at this interval was 100% which is higher than normally encountered. The female mating indices observed for the control group in this study have shown considerable variability ranging from 70.9 to 100% The poor mating performance for the treated groups during the first mating interval is attributed to two males in each treatment group that did not mate either female in their mating unit (each mating unit was comprised of one male and two females).

During the second mating interval of the F2 generation, male mating performance improved in the mid- and high-dose groups as both mid-dose males and one of two high-dose males that did not mate during the first mating interval, mated and impregnated at least one female. Male mating indices for the low-dose group remained unchanged as the same two males that did not mate during the first interval, failed to mate during the second interval. Pregnancy and fertility indices for the treated groups were comparable to control for both litter intervals of the F2 generation.

Mean gestation length was comparable between the control and treated groups for each pregnancy interval in each generation. Over the entire study no consistent, dose-related effect was seen in mating, fertility or pregnancy indices to indicate an adverse effect of treatment.

G. LITTER DATA

Litter size

Mean litter size data on Day 21 of lactation (weaning) was comparable between the control and treated groups for each litter interval throughout the study.

Sex ratio

Pup sex distributions ratios at Day 0 and 21 were generally comparable between the control and treated groups for each litter interval for each generation. No adverse treatment effect on sex distribution data was evident.

Viability index

The mean numbers of live, dead and total pups at birth and pup viability at birth for each pregnancy interval, were comparable between the control and treated groups for each generation. The litter survival indices were comparable between the control and treated groups for each lactation interval in the F0, F1 and F2 generation. In the F0 generation, postnatal survival indices for Days 0-4 and 4-21 were comparable between the control and treated groups for the first lactation interval (F1a). For the second litter interval of the F0, postnatal survival indices for the Day 0-4 interval were comparable between the control and treated groups. During the Day 4-21 interval, survival indices were significantly lower than control in each treatment group. The increase in pup mortality during this interval (i.e. Days 4-21) was attributed to high pup mortality within one or more litters at each treatment level. In the low-dose group the lower pup survival was attributed to one female that experienced complete litter mortality (litter contained 14 live pups at Day 4). In the mid-dose group, one female died on Day 7 of lactation and all seven pups in her litter died during the Day 4-7 lactation interval. Additionally, three mid-dose litters lost five or more pups from their litters during the Day 4-21 lactation interval. In the high-dose group, one female lost nine of l2 pups during the Day 4-21 lactation interval.

In the F1 and F2 generations postnatal survival indices for Days 0-4 and 4-21 during both litter intervals were considered comparable between the control and treated groups. Some statistically significant differences in these indices were observed between the control and treated groups; however, no trend was evident through successive generations to indicate an adverse effect of treatment.

I. PATHOLOGY

Necropsy
F0, F1 and F2 generations
Gross necropsy of parental animals of both sexes did not indicate any adverse effect of treatment.

F1, F2 and F3 offspring
Gross post mortem observations of offspring at weaning (F1a, F2a, F3a, F3b) or post-weaning (F1b, F2b) did not demonstrate an adverse effect of treatment. Likewise, evaluation of dead pups recovered at birth and during the 21–day lactation period did not note a treatment-related effect.

Organ weights
F0, F1 and F2 generations
Mean organ weight data (absolute and relative to body weights or brain weights) were comparable between the control and treated groups for both males and females from the F0 and F1 generations. Some statistically significant differences were noted between control and treated groups both in mean organ weight data and in the relative weight data; however, no trends were evident within dose levels or through these generations.

In the F2 generation, mean organ weight data (absolute and relative) for the males were comparable between the control and treated groups. In the F2 female group, mean liver/body weight ratios were significantly lower than control in each of the treated groups; however, no clear dose-relationship was apparent. Mean liver/brain weight ratios for the treated F2 females were lower than control; however, these differences from control values were not statistically significant. Mean spleen weights (absolute and relative to brain and body weights) were significantly higher than the control value in the F2 mid-dose female group; however, mean spleen weight data for the low- and high-dose F2 females were comparable to control values. In the absence of an effect on spleen weight in the high-dose Fg female group, the change seen in spleen weight data for the mid-dose females was considered spurious and not biologically meaningful. Other mean organ weight data (absolute and relative to body weight or brain weight) for the treated F2 female groups were considered comparable to control data.

F3b offspring
Mean organ weight data (absolute and relative to body weights or brain weights) were comparable between the control and treated groups for both males and females. No treatment-related effect was evident in organ weight data for the F3b offspring.

F
In total 160 male and female rats (40 adults of each generation F0, F1 and F2 and 40 weanlings of F3b) were examined microscopically. No microscopic findings were considered treatment related. Proliferative tissue changes diagnosed as neoplasms were few. The microscopic tissue alterations, neoplastic and non-neoplastic, were indicative of common incidental histological findings.

III. CONCLUSIONS

Study conclusion:
The oral administration of glyphosate to rats by dietary admixture at a maximum dose level of 30 mg/kg bw/day for three successive generations of CD rats resulted in no treatment-related signs of toxicity in parental animals. The NOAEL for reproduction is 30 mg/kg bw/day, since the reproductive performance was not affected in any dose group. The NOAEL for offspring is 30 mg/kg bw/day, since no adverse effects on offspring were observed.

3. Assessment and conclusion

<u>Assessment and conclusion by applicant</u>:

The oral administration of glyphosate to rats by dietary admixture at a maximum dose level of 30 mg/kg

bw/day for three successive generations of CD rats resulted in no treatment-related signs of toxicity in parental animals or offspring. Therefore the NOAEL for reproduction and offspring is 30 mg/kg bw/day, corresponding to the highest dose tested.

Assessment and conclusion by RMS:

Publications on Reproductive Toxicity Studies

A literature search for the active substance glyphosate was performed in accordance to the provisions of the EFSA Guidance "Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) 1107/2009" and updated Appendix to this Guidance document. The following publications were found relevant and reliable for this section and the summaries are thus presented below and are part of the general discussion at the beginning of the section.

In some studies the effects on glyphosate and Round-up formulations have been investigated. In the following, only the effects after glyphosate treatment are discussed.

In the most recent study, a direct effect of glyphosate on Sertolli cell function was investigated under in vitro conditions by Gorga *et al.* (2020) (CA 5.6.1/015). Glyphosate did not modify the expression of the androgen receptor or intercellular junction proteins (claudin11, occludin and ZO-1). Further, intracellular signalling via P-p38-MAPK and P-ERK1/2 pathways were not affected. Lactate production, glucose uptake, GLUT1, FA oxidation, or *FAT/CD36* and *CPT1* expression was unaffected by glyphosate. Thus, the conducted molecular and cell biological investigations indicate that glyphosate does not influence testicular function due to disturbances of nutritional function or metabolism in Sertolli cells. *In vitro* exposure to glyphosate at non-cytotoxic concentrations (10 - 100 ppm) altered Sertoli cell junction barrier permeability and decreased testosterone-stimulated TER. Further, redistribution of claudin11 at the zone of contact between cells was detected after glyphosate stimulation. If the effects observed on Sertolli cell junction barrier permeability may contribute to a postulated effect on male reproductive function cannot be finally assessed. In general, an evaluation of such highly specific cell biological endpoints for hazard assessment is rather difficult as they cannot be transferred easily to intact organisms. As the biological *in vivo* relevance of such "isolated" *in vitro/ex vivo* findings is not validated for intact organisms, an interpretation of the obtained results on the redistribution of one special protein and cell junction barrier permeability is difficlut and not considered sufficiently conclusive.

Manservisi *et al.* (2019) (CA 5.6.1/016) investigated effects of glyphosate in rats exposed to a single dose of 1.75 mg glyphosate acid /kg bw/day (equivalent to the US Acceptable Daily Intake) during pregnancy and lactation and their offspring until adulthood. The study was performed similar to a pilot study according to OECD 443. Reproductive parameters remained to be unaffected by glyphosate exposure. The only significant finding related to glyphosate treatment was increased anogenital distance in pups at PND4 pointing to a delay in male sexual development in a statistically significant manner. In contrast, vaginal opening was not affected by treatment with glyphosate. In male offspring, exposure to glyphosate did not affect BPS or sperm parameters. On hormonal basis, a statistically significant increase in TSH levels was detected in glyphosate treated male rats. Overall, a delay in male sexual development indicated by increased anogenital distance combined with increased TSH level might point to possible androgenic properties of glyphosate. However, number and blood sample collection was limited to the final sacrifice of animals, which is considered as confounding factor. Further, another source of uncertainty is the timing of blood sampling during the necropsy session (9.00 am – 3.00 pm) which does not allow to exclude a circadian-dependent modulation of circulating hormones. The rather high standard deviations in different hormone concentrations might support the uncertainty in the conducted hormone measurements. Furthermore, the biological significance of the altered anogenital distance in pups remains unclear as no similar finding is reported in any available reproductive toxicology studies, including multi-generational studies. In one study performed by [redacted] (2007) (CA 5.6.1/001 – 003) a delay in preputial separation was observed in

male offspring at high doses which indicated a delay in male sexual development. However, the number of animals used in the study performed by Manservisi *et al.* (2019) (CA 5.6.1/016) is considered to be too low to allow a conclusive decision on the biological significance of the observed effects on male sexual development and androgenic properties in male rats. Likewise, the significance of increased TSH levels determined in the performed study is questionable as no histological finding and/or physiological disturbance in the affected animals is reported. For the assessment of possible endocrine actions please refer to section 5.8.3.

The effect of glyphosate on spermatogenesis was tested by Pham *et al.* (2019) (CA 5.6.1/017) in the mouse. Effects on the male reproductive system were analysed in male offspring of glyphosate-exposed pregnant mice treated to 0.5, 5 and 50 mg/kg bw/day. Male offspring derived from treated mice were sacrificed at 5, 20, and 35 days old (d.o.) and 8 months old (m.o.) for analysis. Various parameters were evaluated at different time points, including number of spermatogonia and gene expression in 5–day old mice, testicular histopathology in 20–day old mice, relative weight of testes, epididymis and seminal vesicles, epididymal sperm count, serum testosterone levels, GATA1 positive cell count and ZBTB16 positive cell count in 35–day old mice, and relative weight of testes, epididymis and seminal vesicles and serum testosterone levels in 8-month old mice. No statistically significant change was found for the number of spermatogonia in 5–day old mice. The only genes of which the expression was statistically significantly changed in a dose-related fashion were Bcl2 and Kit. In 20–day old mice, sperm depleted seminiferous tubules were noted at 5 mg/kg bw/day but not at 0.5 and 50 mg/kg bw glyphosate, thereby indictaing a rather incidental finding than a treatment-related effect. In 35–day old mice there was no statistically significant change in the relative weight of the epididymis and the seminal vesicles, epididymal sperm count and GATA1 positive cell count. No dose-effect relationship could be established for relative weight of testes, serum testosterone levels and ZBTB16 positive cell count. In 8-month old mice no statistically significant change was observed for relative weight of epididymis and seminal vesicles and serum testosterone levels. No dose effect relationship could be established for the decrease in relative testes weights. Due to missing dose-responses, the biological significance of the observed findings on seminiferous tubules depletion, relative testes weight, serum testosterone levels and ZBTB16 positive cell count remains questionable. The overall quality of the obtained data is not sufficiently conclusive to indicate test substance-specific adverse effects on testicular function and development when male mice were exposed during early phases in life to up to 50 mg/kg bw/day glyphosate, which has been corroborated by available reproduction toxicity studies with rats at much higher dose levels. In contrast, the data might indicate that glyphosate exposure does not result in long-lasting effects on spermatogenesis after substance withdrawal.

In a further in vivo study, toxic effects on prenatal exposure to glyphosate on lipid metabolism in offspring was investigated Ren *et al.* (2019) (CA 5.6.1/018). A significant decrease in body weight and obvious hepatic steatosis with excessive lipid droplet formation was observed in the offspring. Moreover, the concentrations of lipids such as triglycerides (TGs), total cholesterol (T-CHO), and low-density lipoprotein cholesterols (LDL-C) increased to a significant extent in serum and liver. Furthermore, significant differences in expression levels of genes related to lipid biosynthesis or catabolism in the liver was detected, incl. SREBP1C, SREBP2, Fasn, Hmgcr, Hmgcs and PPARa. Although the authors concluded that there were treatment related effects on foetal and offspring body weight, there is no evidence that glyphosate exposure had any impact on foetal development or pup development postnatally. There was no effect on average birth weight of pups. Further, group mean body weight of pups by sex showed no statistical differences from control. Considering the small group size, the large inter animal variability, the lack of consistency between the same parameter across the sexes, timepoints or sampling matrices, and the reported deficiencies listed in CA 6.6.1/018, it is not possible to clearly attribute any of the observed differences to glyphosate exposure. Therefore, the current study provides no conclusive evidence that glyphosate exposure causes lipid metabolism disruption in offspring following prenatal exposure.

The effects of glyphosate on maturation of isolated mouse oocytes was investigated under in vitro conditions by Zhang *et al.* (2019) (CA 5.6.1/019). Reduced rates of germinal vesicle breakdown (GVBD) and first polar body extrusion (PBE) after treatment with 500 µM glyphosate were reported. Changes in the mRNA expression of related antioxidant enzyme genes (*cat, sod2, gpx*) were interpreted to correlate to

increased formation of intracellular reactive oxygen species (ROS) in mouse oocytes exposed to glyphosate. After 14 h of exposure to glyphosate, metaphase II (MII) mouse oocytes displayed an abnormal spindle morphology and DNA double-strand breaks (DNA-DSBs). Simultaneously, mitochondria showed an aggregated distribution and decreased membrane potential in mouse oocytes exposed to glyphosate. The protein expression levels of apoptosis factors (Bax, Bcl-2) and the mRNA expression levels of apoptosis-related genes (*bax, bcl-2, caspase3*) were measured by Western blot and qRT-PCR, respectively. Meanwhile, the expression levels of autophagy-related genes (*lc3, atg14, mtor*) and proteins (LC3, Atg12) were significantly decreased in the glyphosate treatment group compared with the control group.

Based on these results, the authors hypothesised that glyphosate negatively affected oocyte development and might influence intracellular pathways involved in the cell death machinery.
Although good scientific standards have been applied during conduct of the study, meaning that all experiments have been performed in three biological replicates and at least 50 oocytes have been statistically evaluated using appropriate statistical methods, a sufficiently conclusive assessment on the biological significance of the observed effects is difficult. No distinction between spontaneous or treatment-related causes is possible as only one concentration was applied and hence, an evaluation of a dose-repsonse relationship is not possible which might prove a plausible biological link. Further, it remains unclear why a different number of donor animals was used for different approaches. This narrow source of oocytes limits the robustness of certain conclusions. Furthermore, there are insufficient details reported in the methods to establish whether mice were of the same age before oocyte harvesting.

The effects of glyphosate on testes obtained from rats after exposure to glyphosate over a time period of 14 weeks to 2.5 and 25 mg/kg bw/day (5x and 50x Acceptable Daily Intake, ADI, respectively) was investigated by Johansson *et al.* (2008) (CA 5.6.1/020). No effects were found on the testicular parameters tested, including various endpoints like intra-testicular testosterone levels, expression of Leydig cell specific genes (Cyp11a1, Cyp17a1, Insl3, Hsd3β1 and Star) and expression of somatic marker gene Ar or germ cell marker gene Ddx4, expression of Leydig cell-specific steroidogenesis factors CYP11A1 and STAR. Further, testicular histopathology and apoptosis measurements did not reveal glyphosate induced alterations compared to controls. Thus, glyphosate did not exhibit adverse effects in testes after subchronic exposure.

First results of a subchronic NTP study performed similar to a modified one-generation study are published by Panzacchi *et al.* (2018) (CA 5.6.1/021), describing the effects of glyphosate treatment at the US ADI of 1.75 mg/kg bw/day in rats. Mortality, body weight and body weight gain of dams and offspring was unremarkable. Water and feed consumption during gestation and lactation were not different across groups. Litter sizes were fully comparable among groups. Post weaning water and feed consumption were not affected by treatment. There was no clinical evidence of alterations in activity or behavior, reflexes, eyes or skin, respiratory, gastrointestinal, genitourinary and cardiovascular systems. Thus, no evidence of adverse effects on pregnancy and early life stages due to glyphosate exposure was observed.

A potential effect of glyphosate on ovarian function was investigated by Perego *et al.* (2017) CA 5.6.1/022) in bovine granulosa cells and theca cells under in vitro conditions. Statistically significant effects have been observed at 0.5 and 5 µg/mL (but not at lower test concentrations (0.01 and 0.3 µg/mL)) on cell proliferation in FSH/IGF1 stimulated granulosa cells. The effect was more pronounced at 0.5 µg/mL. Further, estradiol production was reduced only at 5 µg/mL after stimulation with FSH and IGF-1, but not at any other dose. Progesterone production and theca cell proliferation was not affected at any dose. Overall, with the exception of slight, non-dose-related alterations in granulosa cell proliferation under different test conditions and estradiol production at the highest dose tested, this study showed no effects of glyphosate on ovarian function of bovine granulosa and theca cells. Due to the isolated occurrence of the observed effects on proliferation and estradiol production without any dose-response relationship, the biological significance of those findings is rather limited and not considered to indicate hazardous properties of glyphosate on overall ovarion function.

Dai *et al.* (2016) (CA 5.6.1/023) investigated potential toxicity of glyphosate on the male reproductive system in the rat after oral treatment with glyphosate for 5 weeks at dose levels up to 500 mg/kg bw/day. No adverse effects were observed on body weight, food intake, daily weight gain, absolute and relative reproductive organ weight, serum hormone levels, oxidative stress parameters, testicular histopathology and expression of the androgen receptor. A significant decrease in absolute (but not relative) weight of the seminal vesicle and coagulating gland and a decrease in sperm count was determined at the highest dose tested. Likewise, a significant decrease in homogenisation-resistant spermatid count in F0 males was observed at ca 1000 mg/kg bw/day in the study performed by [redacted] (2007) (CA 5.6.1/001 – 003).

In a further study on steroidogenesis, glyphosate was not found to induce any effects on testosterone production (Forgacs *et al.* (2012) (CA 5.6.1/024*)*, thereby indicating that glyphosate did not possess intrinsic properties to influence the steroidogenesis pathway in the applied *in vitro* system.

1. Information on the study

Data point:	**CA 5.6.1/015**
Report author	Gorga, A. *et al.*
Report year	2020
Report title	In vitro effects of glyphosate and Roundup on Sertoli cell physiology
Document No	doi.org/10.1016/j.tiv.2019.104682 E-ISSN: 1879-3177
Guidelines followed in study	None
Deviations from current test guideline	Not applicable
Previous evaluation	None
GLP/Officially recognised testing facilities	No
Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

The aim of the present study was to analyse whether glyphosate (G) and Roundup (R) are able to affect Sertoli cell functions, such as energy metabolism and blood-testis barrier (BTB) integrity. Sertoli cell cultures from 20–day-old rats were exposed to 10 and 100 ppm of G or R, doses which do not decrease cell viability. Neither G nor R caused impairment in lactate production or fatty acid oxidation. G and R decreased Transepithelial Electrical Resistance, which indicates the establishment of a Sertoli cell junction barrier. However, neither G nor R modified the expression of claudin11, ZO1 and occludin, proteins that constitute the BTB. Analysis of cellular distribution of claudin11 by immunofluorescence showed that G and R induced a delocalisation of the signal from membrane to the cytoplasm.

Materials and methods

Materials: [2,6-3H]-2-deoxy-D-glucose (2-DOG) and [9,10(n)-3H] palmitic acid were purchased from NEN (Boston, MA, USA). Culture media, glyphosate and all other drugs and reagents were purchased from SigmaAldrich (St Louis, MO, USA). The glyphosate formulation used in this work was the formulation available on the market called Roundup Full II (Monsanto Argentina S.A.I.C.), which contains 54 % w/v acid glyphosate.

Sertoli cell (SC) isolation and culture: Twenty–day-old Sprague-Dawley rats (Rattus norvegicus) were obtained from the Animal Care Laboratory, Facultad de Ciencias Veterinarias, Buenos Aires, Argentina. Animals were killed by CO2 asphyxiation according to protocols for animal laboratory use following the

principles and procedures outlined in the National Institute of Health Guide for Care and Use of Laboratory Animals. The protocol was approved by the Comité Institucional de Cuidado y Uso de Animales de Laboratorio (CICUAL) from the Hospital de Niños "Dr. Ricardo Gutiérrez". SC were isolated as previously described. Decapsulated testes were digested with 0.1 % w/v collagenase and 0.006 % w/v soybean trypsin inhibitor in Hanks' balanced salt solution (HBSS) for 5 min at room temperature by manual agitation. The enzymatic action was stopped by dilution with four volumes of HBSS. Seminiferous tubules were collected by sedimentation and washed twice with HBSS. Then seminiferous tubules were cut with a razor and submitted to 1M glycine-2mM EDTA (pH 7.4) treatment for 10 min to remove peritubular cells. At the end of the incubation period, nine volumes of HBSS were added and a 30 min sedimentation was performed. The washed tubular pellet was then digested again with 0.1 % w/v collagenase and 0.006 % w/v soybean trypsin inhibitor in HBSS for 10 min at room temperature by continuous pipetting. The enzymatic action was stopped by dilution with four volumes of HBSS. The cell suspension was collected by centrifugation at 200 x g for 3 min. The cell suspension was diluted with HBSS and submitted to a 10 min sedimentation to remove germ cells. The pellet containing SC was filtered through a nylon mesh and SC were recovered by centrifugation at 200 x g for 3 min. SC were resuspended in culture medium which consisted of a 1:1 mixture of Ham's F-12 and Dulbecco's modified Eagle's medium, supplemented with 10mM HEPES, 100 IU/mL penicillin, 2.5 µg/mL amphotericin B, 1.2 mg/mL sodium bicarbonate, 10 µg/mL transferrin, 5 µg/mL insulin, 5 µg/mL vitamin E and 4 ng/mL hydrocortisone. SC were cultured on 6-, 24- or 96-multiwell plates (5 µg DNA/cm^2), on Matrigel-coated cell culture inserts (15 µg DNA/cm^2) placed on 24-multiwell plates or on glass coverslips coated with laminin at 34 °C in a mixture of 5 % CO2:95 % v/v air. No myoid cell contamination was revealed in the cultures when an immunoperoxidase technique was applied to SC cultures using a specific antiserum to smooth muscle α actin. Remaining cell contaminants were of germ cell origin and this contamination was below 5 % after 48 h in culture as examined by phase contrast microscopy.

Culture conditions: SC were allowed to attach for 48 h in the presence of insulin and medium was replaced at this time with fresh medium without insulin. Treatment with glyphosate (G) and Roundup (R) was performed with variable doses and for variable periods of time. Cells incubated for 48 h with 10, 100 and 1000 ppm of G and R harvested on day five were used to evaluate cell viability and LDH leakage. The cells treated for 48 h with 100 ppm of G and R were harvested on day five and used to evaluate GLUT1, FAT/CD36 and CPT1 mRNA levels, glucose uptake and fatty acid (FA) oxidation and the 48 h-conditioned media were utilised to evaluate lactate production. For Western blot studies, cells cultured for 4 days under basal conditions and pretreated for 30 min with 10 and 100 ppm of G or R were used. To quantify Transepithelial Electrical Resistance (TER), SC were cultured at high cell density (15 µg DNA/cm^2, corresponding to 1.2 × ^{106} cells/cm^2) on Matrigel-coated (1,6 dilution with F12/DMEM v/v) cell culture inserts (Millicell HA inserts) (Millipore, Billerica, MA, USA) placed on 24-multiwell plates. On day 3 in culture, testosterone was added and TER across the SC monolayer was recorded every 24 h in culture. On day 5, when the tight junction barrier had been formed, different doses of G or R were added and TER was recorded until day 8. To study the distribution and localisation of claudin11, the cells were cultured on glass coverslips coated with laminin and treated with 100 ppm G or R in the presence or absence of testosterone for 48 h and harvested on day 5.

Evaluation of Sertoli cell energetic metabolism: Energetic metabolism in SC has been considered to have features of its own. Lactate, produced by SC, provides the energetic substrate to germ cells in the adluminal compartment. Consequently, it has been postulated that SC utilizes FA as their energy source. In this context, lactate production, glucose uptake, FA oxidation and the expression of genes involved in these processes were evaluated.

- *Lactate determination:* Conditioned media obtained from cells cultured in 24-multiwell plates were used to determine lactate production. Lactate was measured by a standard method involving conversion of NAD+ to NADH.
- *Measurement of 2-deoxyglucose (2-DOG) uptake:* Glucose transport was studied using the uptake of the labelled non-metabolizable glucose analogue 2-DOG on cells cultured in 24-multiwell plates as previously described.

- *Fatty acid oxidation assay:* FA oxidation was performed measuring the release of ^3H_2O to the incubation medium from [^{3}H]-palmitate on SC cultured in 24-multiwell as previously described.

Evaluation of BTB function: The main component of the BTB is the presence of tight junctions between neighboring SC. In order to evaluate BTB function, Transepithelial Electrical Resistance (TER), claudin11 cellular distribution and the expression of proteins that participate in tight junction assembly were evaluated.

a) *Transepithelial Electrical Resistance (TER) measurement:* The establishment of the SC junction barrier was assessed daily from day 3 to day 8 by measurement of TER across the SC monolayer by a Millicell electrical resistance system (Millipore), as described previously. Briefly, a short (~2 s) 20-µA pulse of current was passed through the epithelial monolayer between 2 silver-silver chloride electrodes and electrical resistance was measured. Electrical resistance was then multiplied by the surface area of the insert to yield the area of resistance in ohms.cm^2. The net value of electrical resistance was then computed by subtracting the background, which was determined by Matrigel-coated cell-free inserts. Each time point had quadruplicate bicameral units. This experiment was run four times on different batches of cells.
b) *Immunofluorescent (IF) detection of claudin11 protein:* Monolayers were fixed with methanol for 10 min at -20 °C. After washes with PBS, cells were permeabilised with 0.1 % Triton X-100 in PBS for 30 min at room temperature. After 3 washes with PBS for 1 min each, the cells were blocked with 5 % bovine serum albumin (BSA). Then, the coverslips were incubated with a 1:50 dilution of polyclonal antibody against claudin11 in PBS overnight at 4 °C. After 3 washes with PBS for 1 min each, coverslips were incubated with an anti-rabbit IgG fluorescein isothiocyanate (FITC)-conjugated (1,25; Vector Laboratories, Burlingame, CA, USA). For negative controls, primary antibodies were replaced by PBS. Finally, the coverslips were washed 3 times with PBS for 1 min each, mounted in buffered glycerine and observed using an Axiophot fluorescent microscope with epi-illumination (Carl Zeiss Inc., Oberkochen, Germany).

RT-Real-time PCR (RT-qPCR): The expression of genes that participate in energetic metabolism (GLUT1, FAT/CD36 and CPT1) and in BTB organisation (occludin, claudin11 and ZO-1) was evaluated by RT-qPCR. Total RNA was isolated from SC cultured in 6-multiwell plates with TRI Reagent (Sigma-Aldrich). The amount of RNA was estimated by spectrophotometry at 260 nm. Amplification was carried out as recommended by the manufacturer: 25 µL reaction mixture containing 12.5 µL of SYBR Green PCR Master mix (Applied Biosystems), the appropriate primer concentration and 1 µL of cDNA. The relative cDNA concentrations were established by a standard curve using sequential dilutions of a cDNA sample. The data were normalised to HPRT1. The amplification program included the initial denaturation step at 95 °C for 10 min, 40 cycles of denaturation at 95 °C for 15 s, and annealing and extension at 60 °C for 1 min. Fluorescence was measured at the end of each extension step. After amplification, melting curves were acquired and used to determine the specificity of PCR products. The comparative ΔΔCt method was used to calculate relative gene expression.

Western blot analysis: Cells cultured in 6-multiwell plates were washed once with PBS at room temperature. Then, 200 µL of PBS containing 2 µL of protease inhibitor cocktail (P-8340; Sigma-Aldrich), 1 mM NaF, 1 mM EGTA, 1 mM EDTA, 50 nM okadaic acid and 2 mM PMSF was added to each well. Cells were then placed on ice and disrupted by ultrasonic irradiation. Western blot analysis was performed as previously described. Membranes were probed with antibodies that allow specific recognition of total Akt and mTOR, phosphorylated p38-MAPK and ERK1/2 (Cell Signaling Technology, Inc., Danvers, MA, USA), claudin11 (Zymed Lab. Inc.), androgen receptor and GAPDH (Santa Cruz Biotechnology, Inc., USA). A 1:1000 dilution of primary antibodies, as indicated by the manufacturer, was used. For chemiluminescent detection of the blots, a commercial kit from Cell Signaling Technology was used. The intensities of the autoradiographic bands were estimated by densitometry scanning using NIH Image Software (Scion Corporation). Levels of the corresponding total Akt, mTOR and GAPDH served as loading controls.

Cytotoxicity: A cell viability test (MTT assay) was performed in cells cultured in 96-multiwell using a commercial kit (CellTiter 96® AQueous NonRadioactive Cell Proliferation Assay; Promega Corporation). Cell cytotoxicity was determined by measuring the activity of LDH enzyme leaked from the cytosol of damaged cells into the medium as previously described. Results were expressed as the percentage of activity detected in the media over the sum of the activities in the media and in cells.
Statistical analysis: All experiments were run in triplicates and repeated 3–4 times. One way ANOVA and post hoc analysis using Tukey-Krämer's multiple comparisons test were performed using InfoStat versión 2016 (Grupo InfoStat, FCA, UNC, Argentina). P values <0.05 were considered statistically significant.

Results
Effects of glyphosate and Roundup on SC cell viability: SC cultures were exposed for 48 h to glyphosate (G) and Roundup (R) at concentrations ranging from 10 to 1000 ppm, corresponding to 0.01 to 1 g/L respectively. Cell viability was analysed by MTT assay and by measuring LDH leaked from the cytosol of damaged cells into the medium. The highest dose tested for R (1000 ppm) caused a cell death (Fig. 1). Therefore, in the present investigation destined to analyse G and R effects on SC functions only doses of 10 and 100 ppm were utilised.

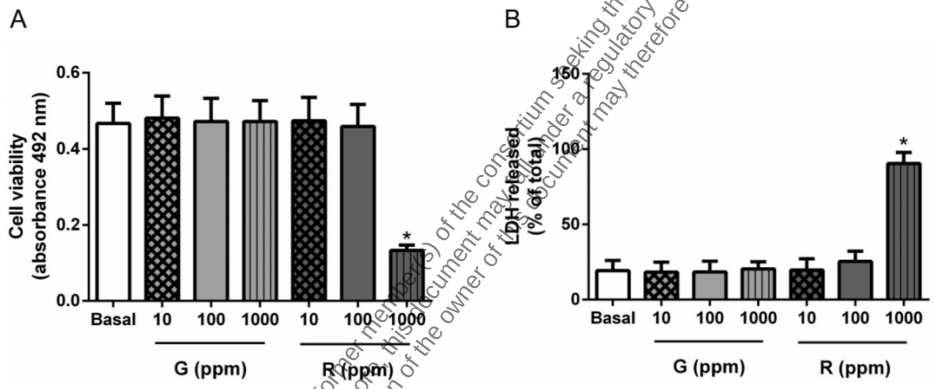

Fig. 1. Effect of G and R on SC cytotoxicity.
SC were maintained under Basal conditions or incubated with 10, 100 or 1000 ppm of G or R for 48 h. (A) Cell viability was determined by MTT assay. (B) LDH activity was determined in SC monolayer and in the culture medium. Values represent mean ± S.D. of one representative experiment out of three. *p < 0.05 versus Basal.

Effects of glyphosate and Roundup on SC energetic metabolism: SC cultures were exposed for 48 h to 100 ppm of G and R. Fig. 2 shows the results obtained for lactate production, glucose uptake and GLUT1 mRNA levels. The exposure to G or R did not modify lactate production neither glucose uptake nor GLUT1 expression.

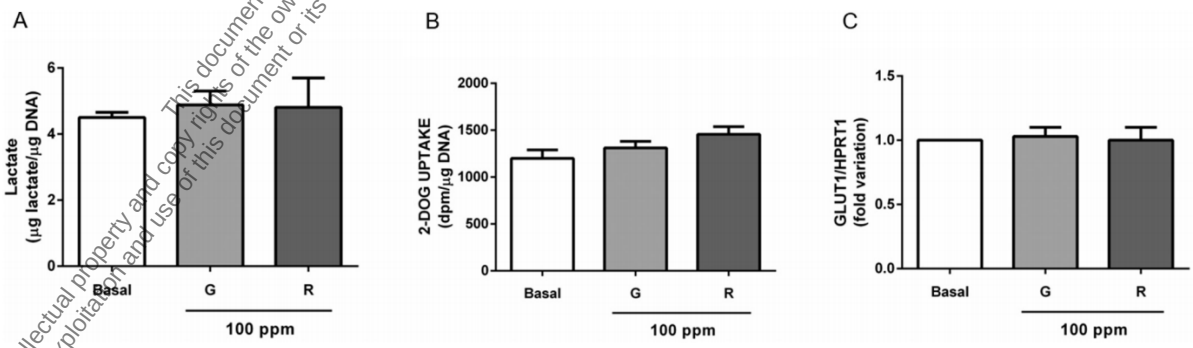

Fig. 2. Effect of G and R on lactate production, glucose uptake and on *Glut1* mRNA levels in SC.
SC were maintained under Basal conditions or incubated with 100 ppm of G or R for 48 h. (A) Lactate levels were determined in the conditioned media. (B) Glucose uptake assay (2-DOG uptake) was performed after the 48 h incubation period. (C) Total RNA was extracted and RT-qPCR was performed to detect *Glut1* mRNA levels. The comparative ΔΔCt method was used to calculate relative gene expression. Graphics show pooled data from four independent experiments performed indicating fold variation in mRNA levels relative to Basal.

Effects of glyphosate and Roundup on blood-testis barrier integrity: SC supply germ cells with a microenvironment preserved by the BTB. The main component of the BTB is the presence of tight junctions

between neighboring SC. The establishment of these junctions between SC in culture was assessed daily from day 3 to day 8 by measuring TER across the SC monolayer. When SC were plated, junctions begin to assemble and an increase in TER was observed. On day 5, when SC completed barrier assembly, G or R were added to the culture medium. Compared with Control (92.3±3.1), a significant decline in TER was produced by the addition of 100 ppm of G (58.0±1.5) or 10 and 100 ppm of R (67.8±2.8 or 62.2±4.9, respectively) (Fig. 4 and Table 2).

Table 2
Effect of 48-h treatment with G and R on TER.

	TER ($\Omega \cdot cm^2$)
Control	92,3 ± 3,1
G 10 ppm	85,5 ± 4,5
G 100 ppm	58,0 ± 1,5*
R 10 ppm	67,8 ± 2,8*
R 100 ppm	62,2 ± 4,9*

SC monolayers were maintained under Basal conditions or treated with 10 or 100 ppm of G or R on day 5 for 48 h. Results are presented as means ± SD of four independent experiments ($*p < 0.05$).

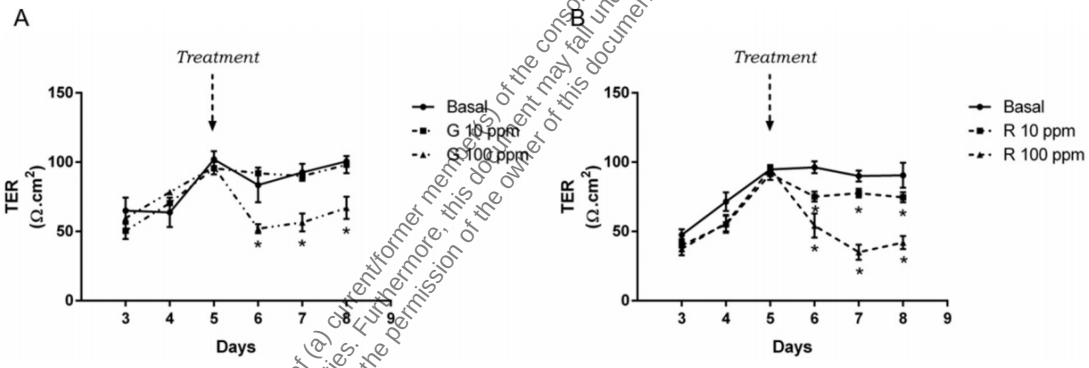

Fig. 4. Effect of G and R on TER across SC.
SC monolayers were maintained under Basal conditions or treated with 10 or 100 ppm of G (A) or R (B) on day 5. TER across SC monolayer was measured from day 3 to 8. Values represent mean ± S.D. of triplicate wells from the same culture of one representative experiment out of four. Asterisks indicate significant differences from basal cultures for each particular day, $p < 0.05$.

Considering that it had been demonstrated that p38-MAPK and ERK1/2 signaling pathways were involved in the disruption of BTB integrity by xenobiotics, the possible alteration of these pathways by G or R treatment was evaluated. R increased P-p38-MAPK and P-ERK1/2 levels. G did not modify P-p38-MAPK and P-ERK1/2 levels at any dose tested. 100 ppm G or R treatment did not modify *claudin11*, neither *occludin* nor *ZO-1* mRNA levels. Claudin11 protein levels were not modify by G or R treatment. In control conditions, claudin11 was detected at the zone of contact between adjacent cells, in a linear and continuous pattern that delineated cell borders in basal conditions. Addition of 100 ppm G or R induced redistribution of claudin11 since immunofluorescence became discontinuous and was redistributed from the cell surface into the cytoplasm.

Effects of glyphosate and Roundup on testosterone regulation of bloodtestis barrier integrity: It is well known that testosterone is the main regulator of BTB function, and that G or R can act as endocrine disruptors. In order to elucidate a possible mechanism responsible for adverse effects of G or R, we decided to evaluate whether herbicides can interfere with androgen action in BTB. Fig. 8A and B shows that 100 ppm G or R treatment did not modify androgen receptor mRNA or protein levels. Fig. 9 shows that, similar to what was observed under basal conditions, 100 ppm G or R treatment induced a redistribution of claudin11 from cell membrane to cytoplasm under the presence of testosterone.

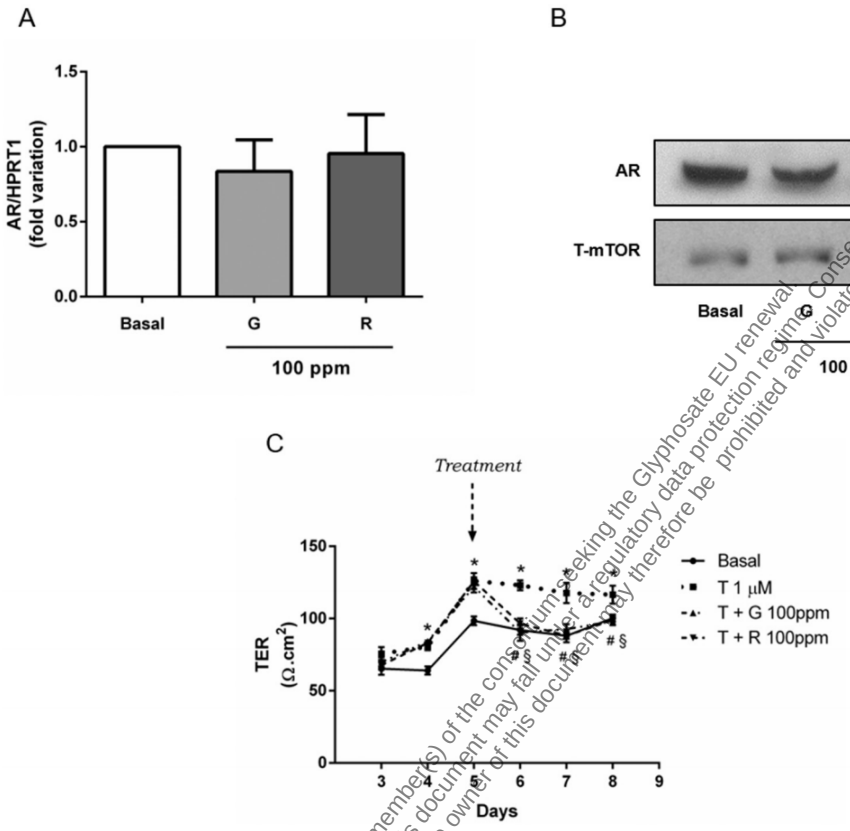

Fig. 8. Effect of G and R on androgen receptor (AR) expression and testosterone regulation of TER across SC.
SC were maintained under Basal conditions or incubated with 100 ppm of G or R for 48 h. A) Total RNA was extracted and RT-qPCR was performed to detect AR mRNA levels. The comparative ΔΔCt method was used to calculate relative gene expression. Graphics show pooled data from four independent experiments performed indicating fold variation in mRNA levels relative to Basal. B) Western blot analysis was performed utilizing antibodies for AR or total Akt (T-Akt). Results are representative of three independent experiments performed/treatment group. C) SC monolayers were maintained under Basal conditions or stimulated with testosterone (T) since day 3. On day 5, SC monolayers were treated with 100 ppm of G or R. TER across SC monolayer was measured from day 3 to 8. Values represent mean ± S.D. of triplicate wells from the same culture of one representative experiment out of three. Symbols indicate significant differences for each particular day: *p < 0.05 T vs Basal; #p < 0.05 T vs T + G; §p < 0.05 T vs T + R.

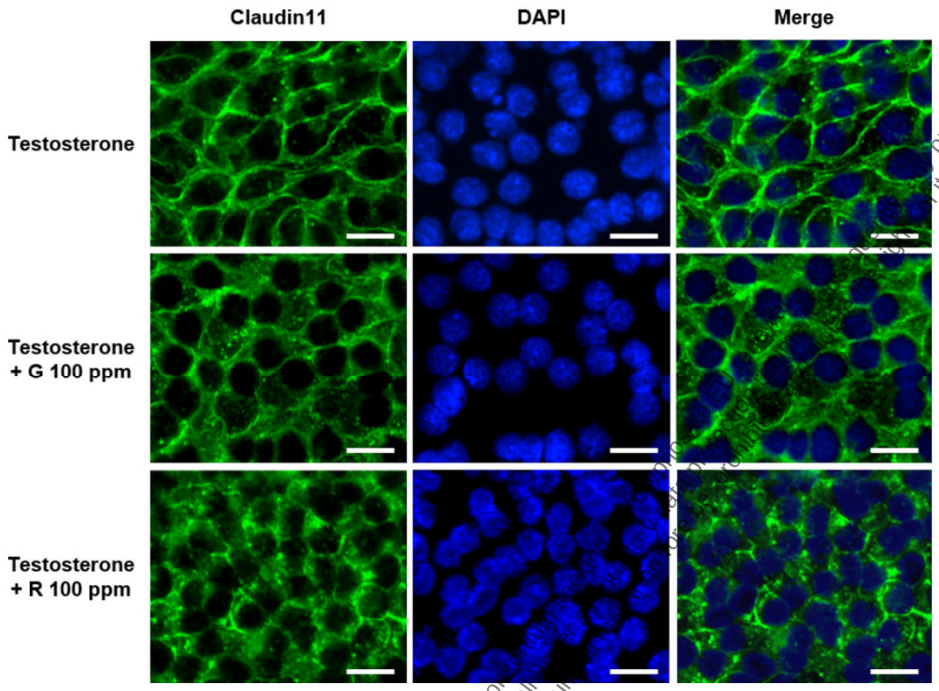

Fig. 9. Effect of G and R on claudin11 localization in the presence of testosterone in SC.
SC were incubated with 100 ppm of G or R in the presence of testosterone for 48 h. Claudin11 was revealed by IF. Bars: 50 µm.

Discussion

Over the last 60 years a progressive decrease in male reproductive function has been observed. Epidemiological and experimental studies suggest that one of the main causes is exposure to environmental toxicants. As previously stated, several studies have shown that G or R can potentially cause adverse effects in male reproduction. Despite the compelling documented evidence proving the existence of adverse effects on testis function, little is known about direct effects on Sertoli cell function and the possible mechanisms involved. Primary cultures of Sertoli cells are a good and reliable model to assess the direct effects of xenobiotic exposure on this cell type. Regarding G and its commercial formulation R, initial studies on Sertoli cell cultures utilizing doses from 1 to 10,000 ppm of G and R were performed. In these experiments, treatment with 1000 ppm R produced Sertoli cell apoptosis with a maximal effect in 24 h-incubation period. However, in the same study G did not induce apoptosis in isolated Sertoli cells. Other studies, which measured apoptosis and/or cell viability, have also demonstrated that several human cell lines are more sensitive to R than to G. Coincidentally, the results presented herein show that 1000 ppm R decreases cell viability while G does not. These differences on the actions of both agents can be interpreted by the presence of various adjuvants in R. These adjuvants change human cell permeability and amplify toxicity by G, which may explain the differences observed between R and G effects on Sertoli cell viability. As we were focused on analyzing possible effects on Sertoli cell function, in this study we utilised 10 and 100 ppm doses which do not decrease cell viability. As mentioned in the introduction, two essential functions of mature Sertoli cells are the provision of nutrients to germ cells and the maintenance of a favorable microenvironment for spermatogenesis. As for Sertoli cell nutritional function, it has been well documented that Sertoli cell glycolysis provides lactate to satisfy germ cell energy demands while FA oxidation supplies energy to fulfill Sertoli cell energetic demands. Consequently, it can be predicted that an alteration in Sertoli cell metabolism can lead to a perturbation in normal germ cell development. The results obtained in the present investigation show that neither G nor R modify lactate production, glucose uptake and GLUT1 expression in Sertoli cells. Additionally, the results show that G and R do not modify FA oxidation and FAT/CD36 and CPT1 expression, proteins that are essential for FA utilisation. Altogether, the results presented herein lead us to conclude that G and R effects on testicular function are not mediated by impairment of Sertoli cell metabolism. Noticeably, other reproductive toxicants, including phthalate esters, nitro-benzene, gossypol and certain heavy metal ions, alter Sertoli cell lactate production and show that

toxicant effects strongly depend on the chemical nature of the toxicant. Regarding lipid metabolism, it has been demonstrated that 24 h exposure to 5000 ppm G or R induce lipid droplet accumulation in the Sertoli cell line TM4 cytoplasm. This increase in lipid droplet accumulation was interpreted as storage of potentially deleterious lipophilic formulants in the cytoplasm of TM4 cells and was considered a sign of the cytotoxic effect. An alternative explanation for the above results would be a modification in lipid metabolism, however, the authors did not explore this possibility. We have explored the latter possibility and the results presented herein show that 100 ppm G and R, doses that do not affect Sertoli cell viability, do not alter FA oxidation. It is worth mentioning that Sertoli cells, in addition to the nourishment provided to germinal epithelia, supply germ cells with a suitable microenvironment for successful meiosis and completion of spermatogenesis. This microenvironment is sustained by the BTB, whose main components are the tight junctions between neighboring Sertoli cells. The BTB is highly dynamic and is regulated by an array of intriguingly coordinated signaling pathways and molecules. Several studies have shown that many environmental toxicants, such as cadmium, bisphenol A, fluoride and sulfur dioxide exert their effects by targeting Sertoli and germ cell junctional proteins, as well as the permeability of the BTB. TER is a widely accepted quantitative technique that measures the integrity and permeability of BTB in vitro. The results presented in this investigation show that 100 ppm G and 10 and 100 ppm R decrease TER after 24 and 48 h-treatment. Notable, the disrupting effect of G on the permeability of other barriers had already been observed. It was shown that exposure to 10 mg/mL (10,000 ppm) G reduces TER and increases permeability to mannitol in Caco-2 and IEC-18 intestinal cell lines. In addition, 1 and 10 µM G treatment (0.16 and 1.6 ppm) decreases TER and increases permeability to fluorescein in iPSC-derived brain microvascular endothelial cells cell line (BMECs). Results from other authors and our own let us postulate that one of the mechanisms by which G exerts toxic effects is related to disruption of barrier properties in different important organs such as intestine, brain and testis. It has been shown that p38-MAPK and ERK1/2 pathways play central roles in the dynamics of BTB. For example, TGFb3-induced physiological effect on Sertoli cell BTB dynamics is mediated via the p38-MAPK pathway. As for toxicant effects, it has been demonstrated that the polychlorinated biphenyls (PCBs), such as congener Aroclor1254, and the perfluorooctane sulfonate (PFOS) can disrupt the BTB integrity by activating the p38-MAPK pathway. The present investigation shows that R increases P-p38-MAPK and PERK1/2 levels. Therefore, it might be suggested that R decreases TER through a p38-MAPK and ERK1/2 dependent pathways. However, the same reasoning cannot be applied to the effects of G considering that it lowers TER while it does not modify P-p38-MAPK and P-ERK1/2 levels. Hence, it seems that there is no direct relationship between P-p38-MAPK and P-ERK1/2 levels and TER levels, at least as a consequence of G and R exposure. We then decided to look for further mechanisms that may be involved in the disruption of BTB integrity by exposure to G and R. The next set of experiments was devoted to analyse possible alterations in the expression of some tight junction proteins, such as occludin, claudin11 and ZO-1, in response to G or R. An increased expression of these proteins, at the time when the junctions are assembled as manifested by a stable TER across the Sertoli cell epithelia, was demonstrated. It is worth mentioning that certain agents that perturb BTB permeability, such as cytokines or toxicants, alter the expression of cell junction proteins. The results obtained in the present investigation show that neither occludin nor claudin11 or ZO-1 expression was modified by G or R treatment. Finally, we decided to investigate whether the cellular localisation of a tight junction protein such as claudin11 could shed some light on the mechanism underlying the decrease in TER. Claudin11 is a key molecule that provides functional integrity to the BTB. It is located in functional Sertoli cell tight junctions and its intracellular distribution pattern changes when gonadotropins are suppressed, coincident with a dysfunctional barrier. Claudin11 null mice are sterile highlighting the importance of this protein for BTB integrity. It is worth mentioning that in men with testicular disorders such as intraepithelial neoplasia, hypospermatogenesis, spermatogenic arrest, and Sertoli cell only testes, claudin11 is located in the cytoplasm, away from the tight junctions reinforcing the idea that localisation of claudin11 in cytoplasm can be considered a sign of BTB dysfunction. In in vitro studies, a direct relationship between TER and localisation of claudin11 in membrane junctions has been observed. The results presented herein show that although G and R treatment does not modify claudin11 protein levels, a redistribution of claudin11 from membrane to cytoplasm is observed. This alteration in the distribution of claudin11 may be interpreted as the result of an increase in membrane protein recycling from cell surface to cytoplasm. This last result may explain, at least in part, the effects of G and R in the integrity of BTB and the deleterious effect of these toxicants at testicular level. Disruption of the Sertoli cell permeability

barrier by loss of usual distribution patterns of other junctional proteins such as occludin, ZO-1, and Cx43 induced by other toxicants has also been demonstrated and these results indicate that redistribution of these proteins can also contribute to alter barrier permeability. Further studies will be necessary to definitively assign a role to this phenomenon in the alteration of BTB dynamics by G or R. Several lines of evidence obtained from in vivo and in vitro approaches highlight the importance of testosterone in the regulation of BTB assembly and function. In vivo studies showed that reestablishment of testicular androgen levels by hCG or testosterone treatment leads to a restoration of claudin11 localisation and BTB function. In vitro studies showed that Sertoli cell permeability barrier formation and claudin11 localisation are promoted by androgen treatment. Furthermore, numerous studies describe G or R as endocrine disruptors. On the one hand, it was demonstrated that in vivo treatment of drakes with R decreases the expression of the androgen receptor (AR) in Sertoli cells while in rats, G treatment does not modify AR expression in the same cell type. On the other hand, it was shown that in vivo treatment of rats decreases serum testosterone levels, and furthermore, it was demonstrated that the effect on testosterone levels may be attributed to a decrease in the expression of STAR in Leydig cells. Therefore, it is tempting to speculate that G or R effects on BTB integrity can be partially attributed to the interference with androgen action. The results presented herein show that neither G nor R treatment modified androgen receptor mRNA and protein levels. They also show that the effects of the herbicides on TER and on claudin11 localisation in the presence of testosterone were similar to those observed under basal conditions. Thus, G and R are able to disrupt BTB function in the presence of testosterone. Further in vivo experiments will be necessary to determine a possible role of G or R as endocrine disruptors.

Conclusion

In summary, this investigation shows that G and R alter the Sertoli cell junction barrier permeability. This study also shows that, at least in part, the loss of location of claudin11 at the interface between neighboring Sertoli cells might be responsible for the disassemble of the barrier. We postulate that BTB integrity is a sensitive target for the adverse effects of G or R on male reproductive function.

7. Assessment and conclusion

Assessment and conclusion by applicant:

This *in vitro* investigation showed that exposure to G and R at 100 ppm alters Sertoli cell (SC) junction barrier permeability, measured by decreased TER, and also decreased testosterone-stimulated TER. This study also showed that, at least in part, the loss of location of claudin11 at the interface between neighboring Sertoli cells might be responsible for the disassembly of the barrier. G or R did not modify androgen receptor mRNA or protein levels, nor did G modify P-p38-MAPK and P-ERK1/2 signalling pathways involved with BTB integrity at any doses tested, or affect the expression of intercellular junction proteins (claudin11, occludin and ZO-1). However, G and R induced redistribution of claudin11 at the zone of contact between cells. Neither G nor R modified lactate production, glucose uptake, GLUT1, FA oxidation, or *FAT/CD36* and *CPT1* expression in SC, thus indicating no effect of G or R on SC nutritional function or metabolism.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used was not sufficiently characterised, there was no positive control and most of the endpoints were tested at only 2 concentrations preventing any dose-response evaluations, with the highest concentration exceeding a physiologically relevant dose.

Reliability criteria for *in vitro* toxicology studies

Publication: Gorga *et al*., 2020	**Criteria met? Y/N/?**	**Comments**
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines	N

Not reliable		
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used was not sufficiently characterised and most of the endpoints were tested at only 2 concentrations.		

1. Information on the study

Data point:	**CA 5.6.1/016**
Report author	Manservisi, F. *et al.*
Report year	2019
Report title	The Ramazzini Institute 13–week pilot study glyphosate-

	based herbicides administered at human-equivalent dose to Sprague Dawley rats: effects on development and endocrine system
Document No	doi.org/10.1186/s12940-019-0453-y E-ISSN: 1476-069X
Guidelines followed in study	Pilot study based on OECD guideline 443: Extended one-generation reproductive toxicity study.
Deviations from current test guideline	Yes, only one dose level for each test item and insufficient number of animals per dose level used.
GLP/Officially recognised testing facilities	No
Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

The present pilot study examines whether exposure to glyphosate-based herbicides (GBHs) at the dose of glyphosate considered to be "safe" (the US Acceptable Daily Intake - ADI - of 1.75 mg/kg bw/day), starting from in utero life, affect the development and endocrine system across different life stages in Sprague Dawley (SD) rats. In pups, anogenital distance (AGD) at PND 4 was statistically significantly increased both in Roundup-treated males and females and in glyphosate-treated males. Age at first estrous (FE) was significantly delayed in the Roundup-exposed group and serum testosterone concentration significantly increased in Roundup-treated female offspring from the 13–week cohort compared to control animals. A statistically significant increase in plasma TSH concentration was observed in glyphosate-treated males compared with control animals as well as a statistically significant decrease in DHT and increase in BDNF in Roundup-treated males. Hormonal status imbalances were more pronounced in Roundup-treated rats after prolonged exposure.

Materials and methods

Chemicals - Glyphosate (purity of > 99.5 %), Pestanal™ analytical standard purchased from Sigma-Aldrich (Milan, Italy). The representative formulated product, Roundup Bioflow (MON 52276, containing 360 g/L of glyphosate acid in the form of 480 g/L isopropylamine salt of glyphosate (41.5 %), water (42.5 %) and surfactant (16 %)) was purchased from Consorzio Agrario dell'Emilia, Bologna, Italy.

Animals and experimental design - Each of the 24 virgin female SD rats (17 weeks old, 270–315 g) was mated outbred with one breeder male rat of the same age and strain. Every day, the females were examined for the presence of sperm. After evidence of mating, females were housed separately during gestation and delivery. Newborns were housed with their mothers until weaning. Weaned offspring were co-housed, by sex and treatment group, not more than 3 per cage. Cages were identified by a card indicating study protocol code, experimental and pedigree numbers, and dosage group. The cages were placed inside a single room at 22 °C ± 3 °C and at 50 ± 20 % relative humidity. A light/dark cycle of 12 hours was maintained. Two groups of dams and their pups were treated with either glyphosate or MON 52276 diluted in drinking water to achieve the desired glyphosate dose of 1.75 mg/kg bw/day. The F0 female breeders received the test item from gestation day (GD) 6 to the end of lactation, while the offspring (F1) continued to be exposed after weaning for an additional 6 or 13 weeks. Glyphosate or MON 52276 solutions were freshly prepared on a daily basis taking into account body weight and water consumption. During pregnancy and lactation, embryos and offspring (F1) were all retained in the litter and received the test compounds mainly through their dams (F0). The day of birth was designated post-natal day 1 (PND 1) for pups and lactation day 1 (LD 1) for dams. After weaning, the offspring (F1) were treated via the drinking water until sacrifice. On PND 28, offspring were randomly distributed in two cohorts: 8/sex/group of the 6–week cohort and 10/sex/group of the 13–week cohort. Altogether, 108 rats (54 males and 54 females) were enrolled in the post-weaning treatment phase.

Measurements in F0 dams and litters prior to weaning - Mean gestational length was calculated as the number of days from detection of a positive vaginal smear (GD 0) to birth of a litter. Pregnancy was

confirmed by the occurrence of parturition. The body weight of the dams was recorded on GD 0, 3, 6 and then daily during gestation until parturition. During lactation, the body weight of the dams was recorded at LD 1, 4, 7, 10, 13, 16, 19, 21 and 25 (last measurement before weaning). Body weight of the pups by sex and litter was determined on PND 1, 4, 7, 10, 13, 16, 19, 21 and 25. Feed and water consumption of the dams was recorded twice weekly during gestation on GD 0, 3, 6, 9, 12, 15, 18, and 21, and twice weekly during lactation on LD 1, 4, 7, 10, 13, 16, 19, 21 and 25. Dead pups were removed when found and sexed when possible. Sex was determined on PND 1. The mean litter size was assessed on PND 0 (within 24 hours from delivery), 1, 4, 7, 10, 13, 16, 19, 21, and 25. Litter size included dead as well as live offspring. Dead pups were visually examined by floating the lungs in saline, to distinguish if they were stillborn (died in utero) or died shortly after birth. Live-birth index was determined on PND 0 as (number of pups born alive / total number of pups born) × 100. Survival index, calculated as (total number of live pups at designated time point / number of live pups born) × 100, was measured on PND 1, 4, 7, 10, 13, 16, 19, 21 and 25. For all the pups, anogenital distance (AGD) was measured and body weight recorded on PND 4.

Post weaning endpoints up to adulthood - After weaning, body weight was measured twice a week, until PND 73 ± 2, then weekly until PND 125 ± 2 and before terminal sacrifice, the means of individual body weights were calculated for each group and sex. Daily water and feed consumption per cage were measured twice a week, until PND 73 ± 2, then weekly until PND 125 ± 2. Time to vaginal opening (VO) was determined by daily inspection of all female pups starting on PND 28. The body weight of each female was recorded on the day VO was observed. Time to balano-preputial separation (BPS) was determined by daily inspection of all males beginning on PND 35. The body weight of each male was recorded on the day BPS was observed. The female rats belonging to the developmental (6–week) cohort were also monitored for the time to first estrous (FE).

Estrous cycle characterisation - Starting on approximately PND 95 and for the duration of 3 weeks, daily vaginal lavage was performed on female rats of the 13–week cohort. To reduce variability, vaginal cytology samples were collected by vaginal lavage at the same time of the day over the course of the experiment, in the mid-morning, between 10:00 and 13:00 h. Collection, processing and vaginal smear evaluation was performed as described previously.

Necropsy - Five days after weaning, dams were sacrificed and following tissues were collected and fixed in alcohol: mammary glands (4 sites: axillary and inguinal, right and left), adrenal glands, uterus (including cervix), ovaries, and vagina. The adrenal glands, uterus and ovaries were also weighed. For the determination of serum testosterone, blood was collected and serum prepared by centrifugation and stored at -80 °C pending analysis. All male and female pups belonging to both cohorts were sacrificed on PND 73 ± 2 for the 6–week cohort and PND 125 ± 2 for the 13–week cohort. Following tissues were collected for histopathology and fixed in alcohol: mammary gland (4 sites: axillary and inguinal, right and left), thyroid and parathyroid, adrenal glands, bladder and prostate, seminal vesicles and coagulating gland, left and right testis with epididymis (half of the right testis and the whole right epididymis were frozen in liquid nitrogen and stored at -80 °C until evaluation), uterus (including cervix), ovaries and vagina. During necropsy, all tissues with gross lesions were removed for histopathology. Adrenal glands, bladder and prostate, seminal vesicles and coagulating gland, left testis, left epididymis, uterus (including cervix) and ovaries were weighed. In case of paired organs, both organs were preserved. Organ weight was expressed as absolute and relative organ weight. Rats were sacrificed randomly across the 4 stages of the estrous cycle. In order to determine and allow correlation with histopathology in reproductive organs and hormone analysis, the stage of estrous cycle was determined by histological appearance of the various components of the reproductive tract for F1 females of the 6–week cohort or by a vaginal smear examined on the day of necropsy for F1 females of the 13–week cohort.

Sperm analysis - Sperm analyses were performed on each male from both cohorts, at scheduled necropsies on PND 73± 2 and PND 125 ± 2. At necropsy, half of the right testis and the whole right epididymis were frozen in liquid nitrogen and stored at -80 °C until evaluation. Spermatids resistant to homogenisation and spermatozoa present in the caput/corpus and cauda epididymis were counted. The tunica albuginea was removed from the (half) testicle, and a sample of the parenchyma was weighed and homogenised in 5 mL

saline-TritonX-100 at 0.05 %. The samples were then diluted 10-20 times in saline, and the mature spermatids resistant to homogenisation (step 17-19 spermatids) were counted using a Thoma chamber. Four fields per animal were recorded, and the numbers of spermatids per gram of testis were calculated. To calculate the daily sperm production (DSP) these values were subsequently divided by 6.1, which is the number of days step 17-19 spermatids are present in the seminiferous epithelium. Similarly, the segments of the epididymis (caput, corpus and cauda) were cut with a scissor, weighed, homogenised, diluted and counted as described for the testes. The number of spermatozoa in each homogenate was determined and the total number of spermatozoa for each segment of the epididymis calculated. The epididymal sperm transit time through the epididymal caput/corpus and cauda was calculated by dividing the number of spermatozoa present in each portion of the epididymis by the DSP of the associated testis. To assess the percentage of morphologically abnormal sperm half of left cauda epididymis of each rat was transferred to a Petri dish containing 2.5 mL (for 70 day old animals) or 3.5 mL (for 120 day old animals) of Dulbecco's PBS at 37 °C, cut in 2-3 pieces and incubated for approximately 3 minutes at 37 °C with gently swirling to facilitate release of sperm cells from the cauda. Dried smears of epididymal spermatozoa were stained with 1 % Eosin Y for 30 minutes and evaluated at 400 x magnification. Five hundred spermatozoa per rat were evaluated and scored as morphologically normal or abnormal according to the presence or absence of head or tail defects.

Histopathology - After fixation, samples were trimmed, processed, embedded in paraffin wax, sectioned to a thickness of 4-5 µm and then processed in an alcohol-xylene series and stained with hematoxylin and eosin for microscopic evaluation. Histopathology evaluation was performed blind by at least two pathologists. At least one senior pathologist peer reviewed all lesions of oncological interest as well as any lesion of dubious interpretation. All the pathologists used the same evaluation criteria and the same classification based on international standard criteria (INHAND, NTP) described in the specific Standard Operating Procedures and long adopted at the CMCRC/RI.

Hormone analysis - Serum concentration of free (fT) and total testosterone (TT), 5α-dihydrotestosterone (DHT), 17β-estradiol (E2) and Sex Hormone Binding Globulin (SHBG) were measured in duplicates by solid phase enzyme-linked immunosorbent assays (ELISAs): "Estradiol rat ELISA" (#DEV9999), manufactured by Demeditec Diagnostics GmbH, "Rat Free Testosterone (F-TESTO) ELISA" (#CSB-E0597r), "Rat Testosterone, T ELISA" (#CSB-E05100R); "Rat dihydrotestosterone (DHT) ELISA" (#CSB-E07879r), and "Rat sex hormone-binding globulin (SHBG) ELISA" (#CSB-E12118r), manufactured by Cusabio Biotech Co. Ltd. The detection range and the Lower Limit of Detection (LLD) of each ELISA kit was 2.5-1280 pg/mL and 2.5 pg/mL for E2, 0.3-60 pg/mL and 0.15 pg/mL for fT, 0.13-25.6 ng/mL and 0.06 ng/mL for TT, 10-2000 pg/mL and 5 pg/mL for DHT, 375-6000 ng/mL and 375 ng/mL for SHBG. Each kit was used following the manufacturer's instructions and absorbance was measured at 450 nm using a 96-well plate reader. Plasma pituitary hormones were measured in duplicate using the "Rat Pituitary Magnetic Bead Panel", a Luminex® bead-based immunoassay, following manufacturers' instructions. Seven plasma pituitary hormones were measured in plasma samples from 40 pups (20 females and 20 males) randomly selected from the 6–week cohort (N = 48 total): adrenocorticotropic hormone (ACTH), brain-derived neurotrophic factor (BDNF), follicle stimulating hormone (FSH), growth hormone (GH), luteinizing hormone (LH), prolactin (PRL) and thyroid stimulating hormone (TSH). FSH and LH were also assessed in 40 pups (20 females and 20 males) randomly selected from the 13–week cohort ($N = 60$ total). BDNF and TSH results from the 6–week cohort showed marginal differences by exposure groups in male pups, it was therefore attempted to validate these results by measuring BDNF and TSH in all male pups ($N = 30$) from the 13–week cohort. Plasma TT was measured in duplicates in all dams ($N = 24$) using an ELISA kit, the "Testosterone Parameter Assay Kit", following manufacturers' instructions.

Statistical methods - Where data on a particular endpoint were collected from both sexes, analyses were conducted separately. All statistical tests were made using a significance level of $\alpha = 0.05$. For continuous data including body weight, weight gain and organ weights, which are most often normally distributed, one-way ANOVA, followed by a Dunnett's test was used to compare treatment versus control groups. For hormone data, which are usually non-normally distributed and have high inter-individual variability, a

screening for outliers was made, based on a Box and Whisker Plot procedure and considering as outliers the values that were outside the box boundaries by more than 3 times the size of the box itself. In the case of hormone ratios, the same outliers of the single evaluation were considered. Nonparametric Kruskal-Wallis' tests, using beta approximation, were used in cases where data were not normally distributed (all hormones). Counting data, not normally distributed, were also analysed with appropriate regression models. Where the observations were grouped (such as for litter data), fixed and mixed effect models were estimated (litter as random effect) and both reported. For bio-logical parameters related to the body weight (such as the AGD), statistical analyses were always performed including the body weight of each pup in the regression model. The incidence of pathological lesions, reported as the numbers of animals bearing lesions, were compared using a two-tail Fisher exact test. The statistical analysis was performed using Stata/IC 10.1 (for all regressions) and Statisti× 10 (for all the other tests); graphs were obtained using Microsoft Excel and Statisti× 10.

Results

No statistically significant differences were observed between the control and the glyphosate and MON 52276 groups for gestational index, mean gestational length, relative weight gain during pregnancy, relative weight gain during lactation, total number of pups delivered at PND 0, litter size, sex ratio, mean life birth index, number of dams with reported stillbirths, number of still born pups, and survival index on PND 1 and PND 21. Also no treatment related effects were observed for water or feed consumption during gestation or lactation. In pups, AGD on PND 4 was statistically significantly increased both in MON 52276 treated males and females and in glyphosate treated males. Results were still significant after running multilevel linear regression models adjusted for body weight and litter as a random effect. Post-weaning body weights as well as water and feed consumption showed no difference in both female and male offspring. In female offspring, age and body weight at vaginal opening (VO) was similar across treatment groups, however, age at FE was statistically significantly delayed in the MON 52276 exposed group. Female offspring in the control and glyphosate treated groups presented the FE within 6 days from the VO, while in the MON 52276 treated group 2/10 females presented a more than doubled interval (12 and 14 days) between VO and FE. In female pups followed up to 13–weeks (N = 30), the percent of time spent in each stage of the estrous cycle did not differ between glyphosate and MON 52276 treated animals and controls. In male offspring, exposure to glyphosate or MON 52276 did not affect BPS or sperm parameters (number of mature spermatids in the testis, daily sperm production, number and sperm transit time through caput/corpus and cauda epididymis and morphology). There were no treatment-related gross lesions in F0 and F1 reproductive and endocrine organs in either sex and there was no statistically significant effect on absolute and relative organ weight of adrenal glands, uterus and ovaries in the dams, adrenal glands, testis, epididymis, bladder/prostate and seminal vesicles/coagulating glands in male offspring (with the exception of a decrease in absolute epididymal weight in the 13–week cohort), and adrenal glands, uterus and ovaries in female offspring.

Most pituitary hormones were unaffected by exposure to glyphosate or MON 52276 in males, with the exception of a statistically significant increase in plasma TSH in the glyphosate group of the 6–week cohort and the MON 52276 group of the 13–week cohort and a statistically significant increase in BDNF in the MON 52276 group of the 6–week cohort. Apart from a statistically significant decrease in DHT in MON 52276 treated males of the 13–week cohort and a statistically significant increase in total testosterone in MON 52276 treated females of the 13–week cohort no effects were found on sex hormones. Hormone ratios were calculated as indicators of the general balance between hormones and sex steroid hormone bioavailability. The TT/SHBG ratio was statistically significantly increased in MON 52276 treated females of the 13–week cohort. The E2/SHBG ratio was statistically significantly increased in MON 52276 treated males of the 6–week cohort. The fT/TT ratio was statistically significantly decreased in glyphosate treated males of the 6–week cohort and in MON 52276 treated males of the 13–week cohort. Male and female MON 52276 treated rats of the 13–week cohort showed a marked and statistically significant decrease in DHT/TT ratio. No such differences were observed for DHT/TT ratio in males and females of the 6–week cohort and no statistically significant differences were observed for the E2/TT ratio in males and females of the glyphosate and MON 52276 treated groups of both cohorts.

Discussion

MON 52276, when administered to rats from in utero through adulthood at a dose level corresponding to the glyphosate RfD defined by the US EPA (1.75 mg/kg bw/day), elicited subtle but potentially adverse effects on reproductive development and hormone concentrations. Overall, these effects indicate an impact on pre- and peri-pubertal sexual maturation. The effects of treatment with glyphosate were essentially limited to increased AGD and TSH concentration, and both changes were specific to males. MON 52276 seemed to affect both females and males, resulting in a statistically significant increase of AGD and sexual hormones imbalances in both cohorts. Statistically significant differences in apical endpoints (AGD and FE) together with changes in hormonal activity detected in both treatment groups should be taken into account suggesting evidence for reproductive toxicity via an endocrine disruption mechanism. A longer AGD at birth in both sexes and an increased age at FE, together with the increased TT in female offspring, are considered endpoints for androgen-mediated activity. The significant increase in AGD and the delay in the appearance of the first estrous cycle observed in MON 52276-treated female rats is consistent with increased developmental androgenisation. The first ovulation is the true endpoint of a series of morphological and functional changes at different levels of the hypothalamic–pituitary–gonadal (HPG) axis, hence, it constitutes the unequivocal sign that puberty has been achieved. No difference in the achievement of vaginal opening (VO) was observed among the groups tested. In males, a prolonged, albeit of low-intensity, androgenizing effect could eventually evoke a counteracting feed-back response from the HPG axis. As apical endpoint, an increased AGD was observed in both treatment groups. Hormone profiling in males, revealed a decreased serum DHT in the MON 52276 group of the 13–week cohort, suggesting an effect on TT metabolism after a prolonged exposure. The lower conversion of TT to DHT might indicate a possible reduction in 5α-reductase enzyme activity. However, this effect was not observed in females of the 6–week cohort. It is of note that males treated with MON 52276 showed normal seminiferous tubules and sperm production which is consistent with the absence of any effect on testosterone and FSH. A statistically significant increase in TSH was observed in glyphosate treated males of the 6–week cohort and MON 52276 treated males of the 13–week cohort. Since no histological changes were observed in the thyroid gland, the increased plasma concentration of TSH can be considered as not indicative of a thyroid related effect. BDNF is a neurotrophin playing a fundamental role in survival and differentiation of selected neuronal populations during development, and in the maintenance and plasticity of neuronal networks during adulthood. A statistically significant increase in BDNF was observed in MON 52276 treated males of the 6–week cohort but not in males of the 13–week cohort. BDNF is an explorative and new endpoint for neurodevelopment and the utility of neurotrophins as potential biomarkers is not completely understood.

The present study has some limitations. First, this is a pilot study performed on a limited number of animals where only one dose was used. However, the dose was selected specifically for its relevance to human health risk assessment, as it is the chronic current RfD defined by the USEPA (1.75 mg/kg bw/day) and therefore a dose level that is expected to be “safe”. Furthermore, the number and timing of blood sample collection was limited to the final sacrifice of animals, considering that this was a pilot study and that *in vivo* blood sampling could lead to maternal and pups stress. Another source of uncertainty, which is currently difficult to assess, is the timing of blood sampling during the necropsy session (9.00 am – 3.00 pm), a circadian-dependent modulation of circulating hormones cannot be completely ruled out. Standard errors in different hormone concentrations were large, in relation to the relatively small group sizes and the physiological variability of hormone concentrations. In females, the estrous cycle status at the time of necropsy is another important source of variability when analyzing sexual hormone profiles. However, even if sacrificing animals on a specific day of the cycle might improve the ability to observe changes in the baseline hormone concentrations, the issue of sacrificing animals in the same cycling period (e.g estrous) is still controversial. The updated OECD Test Guidelines on reproductive-developmental toxicity do not require the sacrifice of females in the same stage of estrous, only the examination of the estrous cycle on the day of necropsy is recommend to allow correlation with the histopathology in reproductive organs. Finally, the adjuvant(s) present in Roundup Bioflow (corresponding to 16% of the formulation) could not be studied since the nature of the co-formulants is a trade secret. These are supposed to be surfactants, diluents or adjuvants stabilizing glyphosate and allowing its penetration in plants. The majority of significant changes observed in hormonal status emerged in the 13–week cohort (animals sacrificed at adulthood) compared to the 6–week cohort (animals sacrificed after puberty) suggesting that more

prolonged exposures were more effective in producing imbalances in the hormone concentrations. In this experiment, MON 52276 was shown to be definitely more potent than glyphosate alone.

Conclusions
The present study demonstrates that exposure to MON 52276 at a dose level equivalent to 1.75 mg glyphosate acid/kg bw/day, from the prenatal period to adulthood, induced endocrine effects and altered reproductive developmental parameters in male and female SD rats. MON 52276 exposure was associated with androgen-like effects, in particular in females, including a statistically significant increase of ano-genital distance in both males and females, a delay of first estrous and increased testosterone in females. MON 52276 exposure was also associated with altered testosterone metabolism in both males and females, where a statistically significant decrease in DHT/TT ratio was observed in the longest treated group (13–week cohort). Overall, MON 52276 elicited more pronounced effects than glyphosate, which only increased anogenital distance and TSH concentration in male rats in the peripubertal window (6–week cohort).

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this pilot study the effect of glyphosate and its reference formulation Roundup Bioflow (MON 52276) at a dose of 1.75 mg glyphosate acid eq./kg bw/day on endocrine modulation was investigated in female rats during pregnancy and lactation, and in male and female rats during lactation, the peripubertal period and adulthood. The endpoints analysed were body weight, water and food consumption, gestational parameters, litter parameters, landmarks of sexual development, estrous cyclicity, gross and histopathology of reproductive and endocrine tissues, sperm parameters and serum and plasma hormone levels. MON 52276 exposure was associated with statistically significant increase of ano-genital distance in males and females, a delay of first estrous and increased serum testosterone in females and altered testosterone metabolism in both males and females. MON 52276 elicited more pronounced effects than glyphosate, which only increased statistically significantly anogenital distance during the peripubertal period. The statistically significant increase in TSH levels in glyphosate and MON 52276 treated rats was not associated with histopathological changes in the thyroid and thus of minor toxicological significance. The effect of glyphosate on ano-genital distance is not corroborated by any reproductive toxicity study where rats were exposed to much higher doses of glyphosate (> 1,000 mg/kg bw/day).

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because of the limited number of animals used per dose level and only one dose level tested.

2. Full summary of the study according to OECD format

This study analysed the effects of glyphosate, alone or in formulation, on the male reproductive system. Pregnant mice were treated from E10.5 to 20 days postpartum by adding glyphosate or a GBH (Roundup 3 Plus) to their drinking water at 0.5 (the acceptable daily intake, ADI dose), 5 and 50 mg/kg/day. Male offspring derived from treated mice were sacrificed at 5, 20, and 35 days old (d.o.) and 8 months old (m.o.) for analysis.

Materials and methods

Chemicals - Glyphosate (purity 99.2 %) was purchased from Sigma-Aldrich, St Louis, USA.

Animals – Four-month-old outbred Swiss adult mice were exposed to glyphosate via the drinking water at concentrations corresponding with 0.5, 5 and 50 mg/kg bw/day from the day of vaginal plug detection (embryonic day 0.5) to 20 days post-partum (dpp). The control group received water alone. Control and treated mice of 5, 20, 35 days old and 8 months old were euthanised and the reproductive organs excised. At least 5 animals derived from at least 3 to 4 different litters in each group were used for this test.

Testosterone quantification - Serum was collected from ketamine/xylazine-anaesthetised adult animals by terminal cardiac exsanguination and aliquots were stored at -20 °C. Testosterone levels in the serum were assayed in duplicate using a commercial radioimmunoassay based on competitive binding with I125-labeled testosterone according to the manufacturer's recommendations.

Epididymal sperm count - The mice were euthanised and the epididymis excised, rapidly frozen in liquid nitrogen and stored at -80°C pending sperm count. The tissue was first cut in pieces and homogenised in 6 mL of 0.15 M NaCl containing 0.005 % (v/v) Triton X-100. After homogenisation by sonication, an aliquot of the cell suspension was loaded onto a Malassez hemocytometer, and spermatozoa heads were counted. The average sperm count was calculated from at least 6 controls or treated animals.

Histology and numbers of germ cells and Sertoli cells - Testis samples were fixed in Bouin's solution and embedded in paraffin. Histological sections (5 µm thick) were stained with hematoxylin and eosin (H&E). For immunohistochemistry (IHC), only the adult animals were perfused and the testes were fixed for 24 hours in 4 % (w/v) paraformaldehyde and then embedded in paraffin. Testis sections (5 µm thick) were incubated overnight at 4°C with a primary rabbit polyclonal antibody DDX4 and then with secondary Alexa-Chicken anti-rabbit 488 antibody during 1 hour to check the number of undifferentiated spermatogonia in testes of mice of 5 days old. For IHC on testes of mice of 35 days old, testis sections (5 µm thick) were incubated overnight at 4 °C with goat anti-ZBTB16 and rat anti-GATA1 and then with secondary Alexa-chicken anti-goat 488 antibody and secondary Alexa-donkey anti-rat 594 during 1 hour. The sections were all counterstained with 0.001 % (v/v) 4,6-diamidino-2-phenylindole dihydrochloride and mounted in Vectashield before microscopic analysis. To quantify the number of Sertoli cells (GATA1-positive cells) and undifferentiated spermatogonia (ZBTB16-positive cells), the cells were manually counted in 30 sections on average of seminiferous epithelium at stage VII in controls and glyphosate treated groups. Cells in 3 different areas of the testis were analysed for each biological replicate

RNA extraction and quantitative PCR - Total RNA was extracted from testes of animals of 5 days old using the RNeasy plus mini kit according the protocol of the manufacturer and reverse transcription was

performed with 1 mg of RNA using the iScript cDNA Synthesis Kit according to the manufacturer's instructions. The resulting cDNA was diluted 5 times and used for quantitative PCR. QPCR was performed using the iTaq Universal SYBR Green Supermix according to the manufacturer's instructions on a CFX384 Touch Real-Time PCR Detection system. The PCR amplification of the coding regions of Actb and Rplp0 was used for normalisation. The data from at least 6 samples were analysed, compared, plotted, and expressed as a fold change in treated samples compared with controls.

Statistical analysis - Statistical tests were carried out using R software. For each experiment, the results were separated and compared by modality. First, the data were tested for normality by the Shapiro test and homoscedasticity by the Bartlett test. If the data distribution for each modality followed a normal distribution and if the variances were equal, the ANOVA test was performed, a parametric comparison test. If the data of at least 1 of the groups were not normally distributed or if the data of the groups were distributed normally but the variances were not equal, the Kruskal-Wallis test was carried out, a nonparametric comparison test of average. The differences were considered statistically significant when $p < 0.05$. In this case, the Tukey test was performed after the ANOVA test and the Mann-Whitney test after the Kruskal-Wallis test. In animals of 5 and 20 days old and 8 months old, data were collected by randomising in view of origin litter and pups were used as the experimental unit for statistical analysis. In animals of 35 days old, corresponding to the first complete wave of spermatogenesis, litters were used as the experimental unit for statistical analysis.

Results

Male reproductive parameters of prepubertal mice of 5 days old – No statistically significant change has been found in the number of spermatogonia of mice exposed to glyphosate at 0.5, 5 and 50 mg/kg bw/day. No statistically significant change has been found in RNA expression of Cyp11a1, Cyp19a1 and Ret at all dose levels tested. Statistically significant changes were observed in RNA expression of Bax (increase at 0.5 mg/kg bw only), Bcl2 (increase at all dose levels), Dazl (increase at 0.5 mg/kg bw/day only), Kit (decrease at 50 mg/kg bw/day only), Sall4 (decrease at all dose levels), Nanos3 (increase at 0.5 and 50 mg/kg bw/day but not at 5 mg/kg bw/day) and Foxo1 (increase at 0.5 mg/kg bw/day only).

Male reproductive parameters of mice of 20 days old - The histopathological analysis of testis sections revealed that glyphosate causes an adverse effect on testis morphology when compared with the control. An increase in vacuoles in the seminiferous epithelium was observed at all dose levels. Empty seminiferous tubules were seen at 5 mg/kg bw/day but not at 0.5 and 50 mg/kg bw/day glyphosate.

Male reproductive parameters of mice of 35 days old – No statistically significant change has been found in relative epididymis weight, relative seminal vesicles weight, epididymal sperm count and GATA1 positive cells. A decrease in relative testes weight was recorded at 0.5 mg/kg bw/day glyphosate but not at the other dose levels. Serum testosterone was found to be statistically significantly decreased at 0.5 and 50 mg/kg bw/day but not at 5 mg/kg bw/day glyphosate. The number of ZBTB16 positive cells were statistically significantly decreased at 5 mg/kg bw/day glyphosate but not at 0.5 and 50 mg/kg bw/day.

Male reproductive parameters of mice of 8 months old – No statistically significant changes were noted for relative epididymis weight, relative seminal vesicles weight and serum testosterone. A statistically significant decrease has been observed for relative testes weight of mice exposed to glyphosate at 0.5 mg/kg bw/day but not at the higher dose levels.

Discussion

Glyphosate did not have any effect on the body weight of animals tested in this study. The decrease in relative testicular weight observed at 0.5 (statistically significant) and 5 mg/kg bw/day (not statistically significant) in mice of at 35 days old and at 0.5 mg/kg bw/day (statistically significant) in mice of 8 months old indicates that glyphosate, even at low doses, can significantly impair spermatogenesis, as testicular weight is a very reliable indicator of the normal function of male reproductive system. This fact was confirmed by measuring the level of testosterone in plasma after glyphosate exposure. In this study, serum testosterone levels were statistically significantly decreased in mice of 35 days old when exposed to

glyphosate at 0.5 and 50 mg/kg bw/day and in mice of 8 months old when exposed to glyphosate at 0.5 mg/kg bw/day but not at higher dose levels. The treatment with different doses of glyphosate did not produce monotonic dose-responses. This is the case for relative weight of the epididymis and seminal vehicles, testosterone levels and sperm counts in mice of 35 days old. Glyphosate exposure led to a non-statistically significant decrease in epididymal sperm count in mice of 35 days old at 0.5 and 5 mg/kg bw/day leading to a non-statistically significant decrease in relative epididymis weight. This decrease in sperm count suggests that exposure to glyphosate could reduce male fertility.

The increase in the expression of key apoptosis genes (Bax, Bcl2) in mice of 5 days old exposed to glyphosate could influence the balance between Sertoli cells and spermatogonia. At 5 mg/kg bw a statistically significant decrease in spermatogonia (ZBTB16 positive cells) number was observed in animals of 35 days old. As the cell count of the pool of undifferentiated spermatogonia in the testes of mice of 5 days old confirmed that there were no changes in the number of germ cells in the glyphosate treatment groups, the decrease in spermatogonia number in mice of 35 days old may be the result of a modification of key genes involved in germ cell differentiation. In this study, there was a decrease in Sall4 and Kit mRNA expression in 5–day old mice exposed to glyphosate. Both factors are part of the retinoic acid (RA)-dependent signalling pathway involved in the differentiation of Aal spermatogonia into A1 which are irreversibly committed in the differentiation process. This result suggests that glyphosate is able to alter spermatogonial differentiation and maturation and this explains, at least in part, the molecular mechanism responsible for the morphological changes observed in 20–day old animals and the decrease in sperm count observed in adults.

Conclusion

This study shows that glyphosate at the ADI dose of 0.5 mg/kg bw/day could have endocrine disrupting effects which could impair the male reproductive system in mice.

8. Assessment and conclusion

Assessment and conclusion by applicant:

The effect of glyphosate exposure from the day of vaginal plug detection to 20 days post partum via the drinking water at concentrations corresponding with 0.5, 5 and 50 mg/kg bw/day on male reproductive parameters in mice of 5, 20 and 35 days old and 8 months old was investigated. The parameters measured were the number of spermatogonia and expression of genes important to testicular function in 5–day old mice, testicular histopathology in 20–day old mice, relative weight of testes, epididymis and seminal vesicles, epididymal sperm count, serum testosterone levels, GATA1 positive cell count and ZBTB16 positive cell count in 35–day old mice, and relative weight of testes, epididymis and seminal vesicles and serum testosterone levels in 8-month old mice. No statistically significant change was found for the number of spermatogonia in 5–day old mice. The only genes of which the expression was statistically significantly changed in a dose-related fashion were Bcl2 and Kit. In 20–day old mice, sperm depleted seminiferous tubules were noted at 5 mg/kg bw/day but not at 0.5 and 50 mg/kg bw/day glyphosate. In 35–day old mice there was no statistically significant change in the relative weight of the epididymis and the seminal vesicles, epididymal sperm count and GATA1 positive cell count. No dose-effect relationship could be established for relative weight of testes, serum testosterone levels and ZBTB16 positive cell count. In 8-month old mice no statistically significant change could be observed for relative weight of epididymis and seminal vesicles and serum testosterone levels. No dose-effect relationship could be established for the decrease in relative testes weight. From these data it can be concluded that there is no evidence that glyphosate dosed orally to mice up to 50 mg/kg bw/day during the perinatal period is an endocrine disruptor and has an adverse effect on testicular function and development. This has been corroborated by reproduction toxicity studies with rats at much higher dose levels.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the test conditions were not clearly described and the number of animals tested per

dose level is too limited.

2. Full summary of the study according to OECD format

The present study aims to investigate the toxic effects of prenatal exposure to pure glyphosate or Roundup on lipid metabolism in offspring. During gestational days (GDs), ICR mice (from Institute of Cancer Research) were given distilled water, 0.5 % glyphosate solution (w/v, 0.5 g/100 mL) or 0.5 % glyphosate Roundup solution orally. The livers and serum samples of the offspring were collected on gestational day 19 (GD19), postnatal day 7 (PND7) and PND21. The results showed a significant decrease in the body weight and obvious hepatic steatosis with excessive lipid droplet formation in offspring. Moreover, the concentrations of lipids such as triglycerides (TGs), total cholesterol (T-CHO), and low-density lipoprotein cholesterols (LDL-C) increased to a significant extent in both the serum and livers. Furthermore, there were significant differences in the expression levels of the genes SREBP1C, SREBP2, Fasn, Hmgcr, Hmgcs and PPARa, which are related to lipid biosynthesis or catabolism in the liver.

Materials and methods

Animals; Ten–week-old female and male ICR mice were purchased from Nanjing Qinglongshan Experimental Animal Center (Nanjing, China). After one week of adaptation, one male and two female mice were housed in each cage from 5.00 p.m. to 8.00 a m. daily to obtain pregnant mice. Pregnant mice were placed into separate cages once the pregnancy was confirmed by a vaginal smear the following morning. This day was defined as the first day of gestation. Animals were fed with water and feed ad libitum. The temperature and relative humidity in the animal house were controlled at 23 ± 2 °C and 50 ± 10 %, respectively, and the animals were kept on a 12-h light/dark cycle. The animal experiments were approved by the Animal Welfare Committee of Nanjing Agricultural University (Nanjing, China) and implemented in accordance with the National Institutes of Health Guidelines for Animal Care and the Committee of Animal Research Institute.

Chemicals and treatment; Pure glyphosate (N-(phosphonomethyl)glycine) and Roundup (as the isopropylamine salt) were provided by Shanghai Ryon Biological Technology Co., Ltd. (Shanghai, China) and Sinochem Crop Protection Products Co., Ltd. (Shanghai, China), respectively. Glyphosate and

Roundup were diluted with distilled water to obtain 0.5 % active ingredient solutions (w/v, 5 g glyphosate/1 L solution). Then, the subjects were administered the 0.5 % glyphosate or Roundup solution through the drinking water (pH was controlled at 7.2 ± 0.2).

Animal treatment and sampling; A total of 30 pregnant mice were randomly divided into three groups: CON (control, n = 10), GLP (0.5 % glyphosate treated, n = 10), and RU (0.5 % Roundup treated, n = 10). Half of the pregnant mice (five from each group) were exposed throughout the first 19 days of pregnancy and were sacrificed on GD19. The other half of the pregnant mice were exposed throughout the pregnancy period and given distilled water after giving birth. Weekly body weights of the offspring were recorded, and their anogenital distances were measured separately to identify their sexes. Seven and 21 days after birth, the prenatally exposed offspring were sacrificed (preferably two females and two males per mother) for blood and tissue analysis. The water consumption of the pregnant mice was measured, and the real exposure dose of glyphosate in both GLP and RU groups was approximately 7 mL (Table 1). The serum was extracted through centrifugation (3500 rpm, 15 min, 4 °C) and was used to assay the biochemical indexes. Parts of the livers were stored at 80 °C for lipid concentration determination and reverse transcriptionpolymerase chain reaction (RT-PCR). Liver samples were either fixed in a 4 % paraformaldehyde solution or embedded in optimal cutting temperature compound (O.C.T. compound) provided by Sakura Finetek Japan Co., Ltd. (Tokyo, Japan) prior to frozen sectioning for the histological observation of tissue sections.

Histological preparation; Some parts of the liver tissue were fixed in 4 % paraformaldehyde solution for 24 h and then dehydrated, clarified, embedded with paraffin and sectioned. Tissue sections (5 mm) were used for hematoxylineeosin (H&E) staining. The remaining liver tissue was embedded with O.C.T. compound and sectioned using a microtome cryostat manufactured by Thermo Fisher Scientific Instrument Co., Ltd. (Shanghai, China) for Oil Red O staining.

Serum biochemical and liver lipid concentration assays; To preliminarily diagnose the liver injury and lipid content of the organisms, the following serum biochemical indexes were determined: aspartate transaminase (AST), alanine transaminase (ALT), triglyceride (TG), total cholesterol (T-CHO), low-density lipoprotein cholesterol (LDL-C), and high-density lipoprotein cholesterol (HDL-C). Additionally, liver homogenate was centrifuged to obtain the supernatant (3500 rpm, 15 min, 4 °C) to measure the TG, T-CHO, LDL-C and HDL-C content. Both the serum biochemical indexes and hepatic lipid content were assayed with commercial reagent kits purchased from the Institute of Biological Engineering of Nanjing Jiancheng (Nanjing, China).

Analysis of gene expression; Total RNA was extracted from liver tissue with the ISOGEN 2 reagent kit (from NIPPON GENE CO., LTD.) (Tokyo, Japan) according to the manufacturer's instructions. The concentration of the obtained RNA was determined by a spectrophotometer, and the purity was measured using a NanoDrop® 8000. Then, PrimeScriptTM RT Master Mix (from Takara Bio Inc.) was used to reverse transcribe RNA to cDNA, which acted as a template for the SYBR® Premix Ex Taq™ PCR kit (from Takara Bio Inc.) for real-time PCR. The expression levels of the genes SREBP1C (Sterol Regulatory Element Binding Protein 1C), SREBP2 (Sterol Regulatory Element Binding Protein 2), Fasn (Fatty acid synthase, which catalyzes fatty acid synthesis), Scd (Stearoyl-CoA Desaturase 1), Acc (Acetyl-CoA Carboxylase), Hmgcr (3-hydroxy-3-methyl-glutaryl-CoA reductase), Hmgcs1 (3-hydroxy-3-methylglutaryl-CoA synthase 1), Hmgcs2 (3-hydroxy-3-methylglutaryl-CoA synthase 2) and PPARa (Peroxisome proliferator-activated receptor alpha) were determined. The relative expression levels of the above genes were normalised to b-actin expression. All primers were designed and supplied by GenScript Bio-Tech Co., Ltd. (Nanjing, China).

Data analysis; The software packages SPSS Statistics 20.0 and GraphPad Prism (GraphPad Software, San Diego, CA, USA) were utilised to analyse the data. One-way analysis of variance (ANOVA) and Tukey's multiple comparison tests were performed. Values are expressed as the mean ± standard error of the mean (SEM), and statistical significance was set as $p<0.05$.

Results

Table 1: Effects of chronic glyphosate exposure on the performance of pregnant mice.

Items	CON	GLP	RU	*P*
Water consumption (ml)	9.69 ± 0.76^{a}	7.88 ± 0.46^{b}	7.45 ± 0.34^{b}	0.023
Feed intake (g)	9.00 ± 0.16	8.32 ± 0.55	9.63 ± 0.72	0.261
Body weight gain (g)	32.60 ± 3.30	35.96 ± 2.92	29.84 ± 0.70	0.281
Number of fetuses (n)	10.80 ± 1.50	14.40 ± 1.57	12.60 ± 2.11	0.376
Average birth weight (g)	1.73 ± 0.13	1.65 ± 0.08	2.03 ± 0.72	0.220

Each value represents the mean ± SEM of the group (n = 5).
Different letters indicate statistically significant differences. a, b $p < 0.05$.

Physical and organ development; From GD19 to PND21, the body weight in both GLP and RU groups decreased and finally saw a statistically significant reduction on PND21 ($p<0.05$) (Fig. 1). When separated according to sex, offspring showed no significant differences in either body weight or weight gain among the three groups (Table 2).

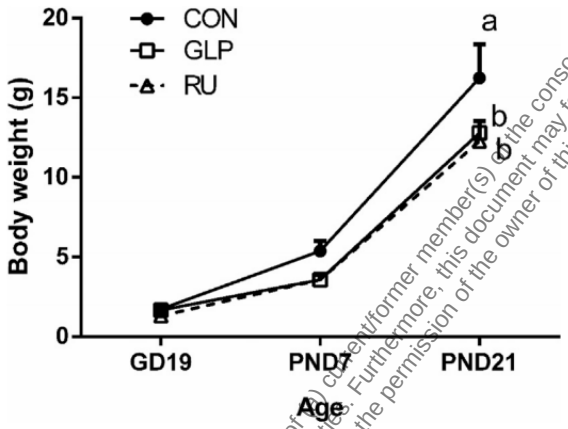

Figure 1: Effects of chronic glyphosate exposure to pregnant mice on the body weights of offspring at the ages of GD19, PND7 and PND21 (mean ± SEM). Different letters indicate statistically significant differences, p<0.05.

Table 2: Effects of chronic glyphosate exposure to pregnant mice on the physical development of the offspring (g).

Each value represents the mean ± SEM of the group (n = 7–10).

Liver histological observation; In both GLP and RU groups, relatively elevated numbers of vacuoles exhibiting hepatic lipid droplets were observed within the hepatocytes of both female and male offspring, when compared with the CON group. Additionally, the red areas observed in the Oil Red O stained sections represent lipid substances. In females, there tended to be more lipid droplets in the GLP group than in the other two groups. In contrast, in males, both the GLP and RU groups showed excessive lipid deposits. In

addition, there were several clusters of monocytes in both the GLP and RU groups of PND7 females. It appears that glyphosate could cause inflammation in early-aged female mice.

Serum biochemical index; Compared with the CON group, TG levels showed a significant increase in the GLP group in both GD19 foetuses (p<0.01) (Table 3) and PND21 female mice (p<0.05) (Table 4). With respect to T-CHO levels, GLP mice showed a remarkable increase in both PND7 males (p<0.01) and PND21 females (p<0.05) compared with CON mice. LDL-C levels also increased in PND7 mice in both the GLP and RU groups (p<0.05) (Table 4). The increased lipid content reflects the adverse effects of glyphosate on lipid metabolism, although this disturbed effect was not detected in every individual. Furthermore, significantly elevated AST levels in PND7 females in the RU group (p<0.01) are theoretically considered to be a result of an injured liver.

Table 3: Effects of chronic glyphosate exposure to pregnant mice on the blood biochemical indexes in foetuses.

Different letters indicate statistically significant differences. a, b $p < 0.05$.

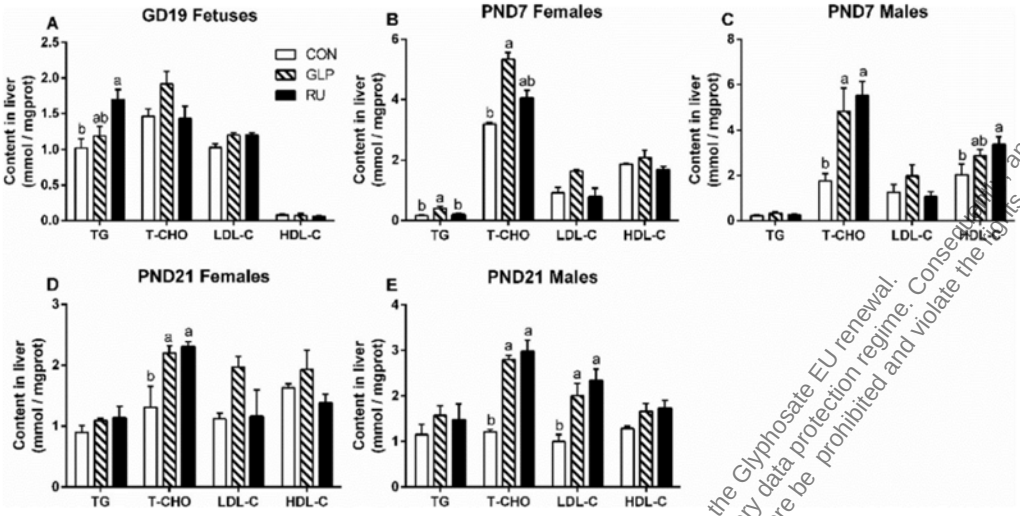

Figure 2: Effects of chronic prenatal glyphosate exposure on the lipid content in the livers of the offspring (mean ± SEM). (A) shows the TG, T-CHO, LDL-C and HDL-C content in livers of GD19 foetuses, and (B), (C), (D) and (E) show these parameters in PND7 and PND21 females and males, respectively. Different letters indicate statistically significant differences. a, b $p<0.05$.

Lipid concentration in the liver; Compared with that in CON mice, TG levels in the RU group significantly increased in GD19 foetuses and PND7 female offspring ($p<0.05$) (Fig. 2A and B). Moreover, T-CHO levels of both PND7 and PND21 offspring increased in the GLP or RU groups ($p<0.05$) (Fig. 2B-E). Elevated TG and T-CHO levels in the liver can probably cause lipid deposits. The LDL-C levels of PND21 males showed a noticeable increase in both the GLP and RU groups ($p<0.05$) (Fig. 2E), and the HDL-C levels in PND7 males were elevated in the RU group ($p<0.05$) (Fig. 2C). Both low-density and high-density lipoproteins can transport cholesterol in the extracellular environment. The elevated level of these proteins in serum is considered to be the result of increased cholesterol levels.

Expression levels of genes related to lipid metabolism in the liver; The relative expression levels of the genes SREBP1C, SREBP2, Fasn, Acc, Scd, Hmgcr, Hmgcs1 and Hmgcs2 in the GLP and RU groups showed a significant increase in GD19 foetuses and PND7 and PND21 offspring ($p<0.05$) (Fig. 3). These genes are closely related to hepatic lipid production, so their elevation contributes to increased fat storage. However, this kind of increase does not match well to the trend in serum lipid content alteration. The levels of PPARa in PND7 males and PND21 females increased remarkably in both the GLP and RU groups, which is likely due to the growing demand for lipid catabolism caused by the increased lipid content.

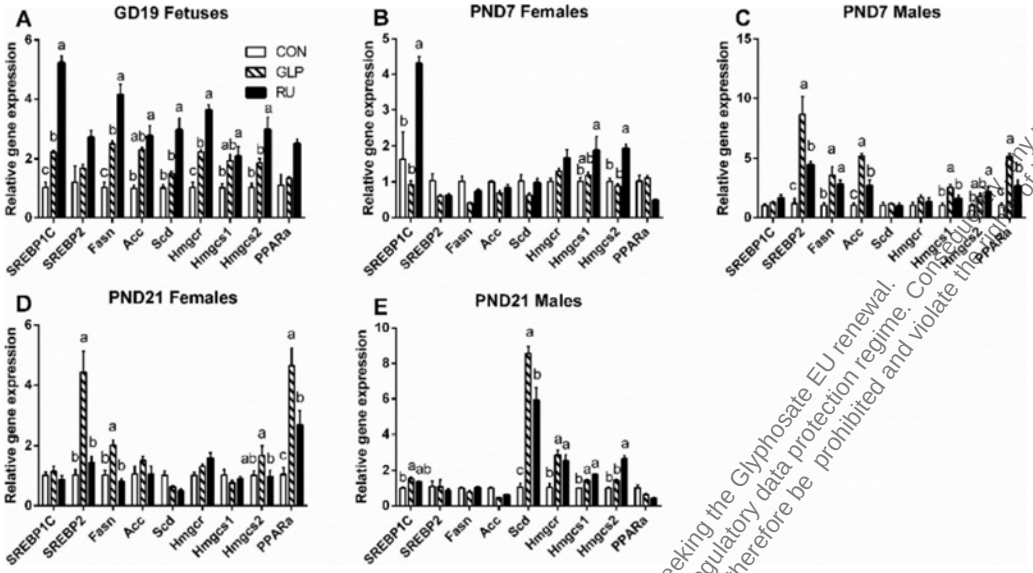

Figure 3: Effects of chronic prenatal glyphosate exposure on relative mRNA expression levels in the livers of the offspring (mean ± SEM). The relative expression levels of the genes SREBP1C, SREBP2, Fasn, Acc, Scd, Hmgcr, Hmgcs1, Hmgcs2 and PPARα genes in the livers of (A) foetuses, (B) PND7 female offspring, (C) PND7 male offspring, (D) PND21 female offspring, and (E) PND21 male offspring are shown. Different letters indicate statistically significant differences. a, b $p<0.05$.

Discussion

Previous studies have found that glyphosate could cause fatty liver disease at the level of transcriptome and proteome. The transgenerational potential of glyphosate between dams and their litter successfully raises concerns about the hepatotoxicity of glyphosate in the progeny. The present study was designed to study the toxic effects of chronic prenatal glyphosate exposure on lipid metabolism in the livers of offspring. The results suggested that chronic maternal exposure to glyphosate can lead to the disruption of lipid metabolism in the next generation. In the present study, 19 or 21 gestational days was typically chosen as the exposure period, and offspring were collected on gestational day 19 and after birth on PND7 and PND21. The average water consumption in the GLP and RU groups was approximately 7 mL, which means that the pregnant mice took an average of 35 mg glyphosate per day. Thus, the real glyphosate exposure dose in foetuses was probably less than 35 mg per day. To our knowledge, the median lethal dose (LD50) of glyphosate in mice is 5000 mg/kg body weight (bw), and the non-observed adverse effect level (NOAEL) is 500 mg/kg bw/day. Although the true administered dose of glyphosate that the offspring received in the present study is far lower than the NOAEL, several phenomena still revealed excessive lipid production. Additionally, according to the classification criteria of the EU and the OECD Globally Harmonised System, glyphosate is not listed as an acute oral toxin based on 145 studies. In chronic exposure research, the "overall NOAEL" was assessed to be 100 mg/kg bw per day based on human beings, which is also higher than the present study's dose. Taken together, a dose lower than overall NOAEL can still cause hepatic lipid metabolism disruption, although the consistency is not perfect among the tested parameters and groups in this study. Physical development is used as an important indicator of the health state of organisms. The body weights of the prenatal glyphosate-treated offspring showed a reduction compared to that of the CON group, which is in accordance with the previous results. The adverse effects on the physical development of offspring could be explained by the decreased body weight of the pregnant mice, while the feed intake of the pregnant mice showed no statistically significant changes. Therefore, the reduced body weight might be the result of energy consumption for the purpose of detoxification instead of for physical development. The liver is the most important detoxification organ that works to metabolize xenobiotics and can reflect the risk of the xenobiotics to the body system to some extent. To observe the liver state of the prenatally exposed offspring at the level of histology, H&E and Oil Red O staining were implemented in the present study. A relative increase in the number of fat vacuoles can be seen in several photomicrographs in the GLP

or RU groups compared with the CON group, which is probably due to the elevated TG and T-CHO levels determined in both the serum and liver. Lipid production and storage in organisms are mainly controlled by liver lipogenesis and catabolism. We learned from the related gene expression level data that the genes related to these two biological processes showed increased expression levels in the GLP and RU groups compared with the CON group. SREBPs are essential activators for the synthesis of fatty acids and cholesterol once combined with a lipid synthesis promoter. SREBP1c, one of the isoforms of SREBP1, regulates the process of lipogenesis that increases from the early age of GD19, while SREBP2 is responsible for cholesterol biosynthesis. Furthermore, the increasing expression levels of downstream genes, such as Fasn, Scd, Acc, Hmgcr and Hmgcrs, contribute to higher fatty acid and cholesterol biosynthesis, which could result in inevitable hepatic fat storage. For lipid catabolism, PPARa plays a crucial role in mitochondrial b-oxidation and peroxisomal fatty acid oxidation, both of which act as important biological reactions in the degradation of liver lipids. Increased PPARa levels in the prenatally exposed offspring might be due to the growing demand for lipid catabolism caused by the rising TG or T-CHO levels. However, the alterations in gene expression are not completely consistent with TG or T-CHO synthesis proteins level or fat storage in the liver sections. This finding might be due to the limited number of subjects, and we will try to explore more detailed reasons and explain these reasons in our future studies. Taken together, we believe that glyphosate could affect lipid production by disturbing lipid metabolism-related gene expression. Previous research had detected a time-dependent enhancement in triglyceride and cholesterol levels as glyphosate-treated subjects aged, whereas there were contradictory results shown in bullfrog tadpoles. To explore more mechanistic insights, a lipidomic profiling experiment was conducted, and 62 distinct lipid species were identified as altered, including triglycerides and cholesteryl esters. Additionally, glyphosate is found to be metabolised into glyoxylate, which inhibits fatty acid oxidation enzymes, all of which are considered to be tightly associated with hepatic lipid dysregulation. Together with the reported impairment of mitochondrial oxidative phosphorylation and enzymatic activity after glyphosate treatment, the efficiency of the respiratory rate and tricarboxylic acid cycle will inevitably decline, which could further induce the diversion of redundant fatty acids into other lipid metabolism pathways. There have been many studies on glyphosate-induced chromosome and DNA aberrations spanning more than 20 years. A great variety of species as well as different doses of glyphosate were used in these studies. The reactive oxygen species and oxidative injury caused by glyphosate or its metabolites are commonly thought to be the reason for the genotoxicity. In the present study, glyphosate's genotoxicity was highly likely reflected in the disruption of lipogenesis. Glyphosate also caused obvious liver damage that appeared in the hematological parameters and histopathological alterations. The increased serum ALT and AST levels in prenatally exposed offspring demonstrated severe liver damage, similar to a reported study. The leakage of liver enzymes is a remarkable indicator of hepatic injury owing to xenobiotics. Additionally, the discovery of clusters of monocytes suggested the presence of inflammatory infiltration and immune responses, but it was not widely observed in all treatment groups. Apart from the liver lesions presented in our study, leukocyte infiltration, necrosis, blood congestion, hydropic degeneration and sinusoid dilation, which could enhance the risk of glyphosate-induced steatosis progression into fatty liver disease, has been observed in hepatocytes in other experiments. Therefore, it is probable that glyphosate-induced lipid metabolism disruption could progress into steatosis if no recovery or interference therapy was performed. Although significant differences were observed between some groups, the changes in the histopathological alterations, blood biochemical indexes and expression levels of lipid metabolism related genes among the groups showed imperfect consistency. This result is highly likely caused by the limited quantity and individual variation of the subjects. Additionally, there are other factors that could have affected the results, such as sex, age and glyphosate source. Considering that the main aim of the present study was to explore the hepatotoxicity of glyphosate exposure, especially during pregnancy, on the lipid metabolism of offspring, these other factors will be future projects and will be studied in future research.

Conclusion

Chronic prenatal glyphosate exposure can probably cause lipid metabolism disruption in offspring, accompanied by an elevated lipid content in both serum and liver tissue. These alterations in hepatic lipid metabolism might result from rising lipogenesis in hepatocytes through increasing related gene expression.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The current study aimed to examine any effects on lipid metabolism in foetuses and pups following prenatal exposure to glyphosate or the glyphosate formulation, Roundup™. Ten pregnant female rats per group were exposed from gestation day 1 through 19 to drinking water containing either 0.5 % glyphosate, prepared using "pure" glyphosate (N-(phosphonomethyl) glycine), or 0.5 % glyphosate using an appropriate dilution of Roundup™. A similar group of animals were given distilled water and served as the control group. Five females per group were terminated on gestation day 19 for examination of foetuses, while the remaining dams were allowed to litter and maintain their litters to postnatal day 21. Offspring (2/sex/litter where possible) were selected on postnatal days 7 and 21 for evaluation. Foetal and offspring evaluations included liver histology, serum biochemistry, liver lipid concentration and gene expression analysis of genes related to lipid metabolism in the liver.

The study is non-GLP and does not report the following information:

- Purity of test items
- Body weight and clinical signs for pregnant animals
- Clinical observations of offspring
- Achieved dose of glyphosate in treated animals in mg/kg bw/day.
- Measures to control inter animal and intergroup variability such as
    - Time of necropsy distributed equally across groups
    - Standardisation of litter size on day 4 of lactation to mitigate variability caused by differences in liter size.
- More than a single dose level of glyphosate (0.5 % solution); thus, preventing dose-response characterisation
- Liver weight of foetuses or offspring
- Normal physiological ranges for serum and liver biochemistry in this strain of rat at this laboratory
- Clear reporting of statistical evaluation and differences
- Thorough histological evaluations of the liver with incidence and severity of any recorded findings.

Although the authors concluded that there were treatment-related effects on foetal and offspring body weight, there is no evidence from this study to suggest that glyphosate exposure has had any impact on foetal development or pup development postnatally. There was no effect on average birth weight of pups, the slight difference observed in the glyphosate-treated group should be attributed to the slightly larger mean litter size observed (14.4 pups compared to 10.8 in the control group). Although figure 1 shows a reduction in mean pup weight in the glyphosate and Roundup™ treated groups (male and females combined). Group mean body weight of pups by sex showed no statistical differences from control.

Given the small group size, the large inter animal variability observed, the lack of consistency between the same parameter across the sexes, timepoints or sampling matrices, and the deficiencies listed above, it not possible to clearly attribute any of the observed differences to glyphosate exposure. Therefore, the current study provides no evidence that glyphosate exposure causes lipid metabolism disruption in offspring following prenatal (in utero) exposure.
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used is not sufficiently characterised, only one dose level was tested, there was large inter animal variability observed and too few animals per dose level were analysed.

2. Full summary of the study according to OECD format

The effects of glyphosate on oocyte maturation, as well as its possible mechanisms remain unclear. The present study revealed that mouse oocytes had reduced rates of germinal vesicle breakdown (GVBD) and first polar body extrusion (PBE) after treatment with 500 µM glyphosate. Reactive oxygen species (ROS) were found in mouse oocytes exposed to glyphosate, as shown by changes in the mRNA expression of related antioxidant enzyme genes (*cat, sod2, gpx*). After 14 h of exposure to glyphosate, metaphase II (MII) mouse oocytes displayed an abnormal spindle morphology and DNA double-strand breaks (DNA-DSBs). Simultaneously, mitochondria showed an aggregated distribution and decreased membrane potential in mouse oocytes exposed to glyphosate. The protein expression levels of apoptosis factors (Bax, Bcl-2) and the mRNA expression levels of apoptosis-related genes (*bax, bcl-2, caspase3*) were measured by Western blot and qRT-PCR, respectively. Meanwhile, the expression levels of autophagy-related genes (*lc3, atg14, mtor*) and proteins (LC3, Atg12) were significantly decreased in the glyphosate treatment group compared with the control group.

Materials and methods

Antibodies and chemicals: Rabbit polyclonal anti-LC3A/B (light chain 3, LC3), anti-p-MAPK, anti-g-H2AX and anti-b-actin antibodies were purchased from Cell Signaling Technology. Mouse monoclonal anti-Bax, anti-Bcl-2, antiAtg12, anti-Annexin V and anti-α-tubulin antibodies were purchased from Santa Cruz Biotechnology. The Reactive Oxygen Species Assay Kit was purchased from Beyotime Biotechnology (S0033). The Mitochondrial Membrane Potential Assay Kit with JC-1 was obtained from Beyotime (C2005). Mito Tracker Red CMXRos was purchased from Cell Signaling Technology (#9082).
Mice: Female Kunming mice (25-30 g) were purchased from the Institute of Zoology, Chinese Academy of Sciences. They were housed in a temperature-controlled room with 12D:12L (dark vs. light) and had unrestricted access to food and water under conditions of constant temperature (23 ± 2° C).

Oocyte collection and treatment: To collect fully grown GV oocytes, the mice were superovulated by injecting them intraperitoneally with 10 IU Pregnant Mares Serum Gonadotropin (PMSG) 48 h earlier. The mice were sacrificed by cervical dislocation and the ovaries were placed in M2 medium. Oocytes were released from the ovaries by puncturing the follicles with a fine needle, and denuded oocytes were collected by gentle pipetting. GV oocytes were cultured in an incubator in 50 µL droplets of culture medium under liquid paraffin oil at 37 °C in 5 % CO_2. Glyphosate was dissolved in M16 medium and diluted to a final concentration of 50, 100, 200 or 500 µM. After culturing for 2 h or 14 h, GVBD and MII oocytes were used for the subsequent experiments.

Immunofluorescent staining: To determine the levels of intracellular ROS production, denuded MII oocytes from 6 mice were incubated with M16 medium that contained 10 µM dichlorofluorescein diacetate (DCFH-DA) for 30 min at 37 °C in the dark. After washing three times with 1 % Bovine Serum Albumin/Phosphate-buffered saline (BSA/PBS), the oocytes were placed in 50 µL of M16 medium droplets and the fluorescence was observed with a confocal laser-scanning microscope (Zeiss LSM 710 META, Germany) with the same scanning parameters. The fluorescence intensity of each oocyte was analysed using ImageJ software. For mitochondrial staining, MII oocytes from 6 mice were fixed in 4 % paraformaldehyde (PFA) for 1 h and then placed in membrane permeabilisation solution containing

0.5 % Triton X-100 for 20 min at room temperature. After washing three times with 1 % BSA/PBS, the oocytes were incubated in 200 nM Mito Tracker Red CMXRos in M16 medium for 30 min in the dark. After several washes, the oocytes were costained with DAPI (4', 6-diamidino-2-phenylindole) for 5 min. Images were captured by the confocal laser-scanning microscope. To measure mitochondrial membrane potential (MMP), MII oocytes from 6 mice were incubated at 37 °C for 20 min with the 1 x JC-1 probe, then washed twice with JC-1 buffer (5 min each) to remove surface fluorescence. Images of fluorescence were captured using confocal microscopy as above. MMP was quantified as the ratio of red to green fluorescence using ImageJ software. To measure the spindle, apoptosis, autophagy and DNA damage, MII oocytes from 24 mice were stained with anti-α-tubulin, antiAnnexin-V, anti-LC3and anti-γ-H2AX antibodies, respectively. The denuded MII oocytes were fixed with 4 % PFA for 30 min, permeabilised in 0.5 % Triton-X 100 for 20 min at room temperature, and blocked with 1 % BSA/PBS for 1 h at 4 °C. The oocytes were incubated with anti-α-tubulin (1:200), anti-LC3 A/B (1:200), antiAnnexin-V (1:200) and anti-γ-H2AX (1:200) at room temperature for 2 h followed by three washes with 1 % BSA/PBS. The oocytes were then incubated with an appropriate secondary antibody for 2 h at room temperature and then costained with DAPI for 5 min in the dark. After three washes, oocytes were mounted on a glass slide and representative images were captured by the confocal laser-scanning microscope. ImageJ software was used to quantify the fluorescence intensity in the images.

Quantitative real-time PCR: Total RNA was extracted from 100 MII oocytes from 12 mice using the TRNpure Total RNA Kit (Nobelab, Beijing, China) according to the manufacturer's instructions. The first strand cDNA was generated with the PrimeScript™ RT Reagent Kit with gDNA Eraser (Perfect Real Time) (Takara, China). All gene expression was determined using the FS Universal SYBR green PCR master mix (Roche, Canada) under the following conditions: 50 °C for 2 min, 95 °C for 10 min, 40 cycles of 95 °C for 15 s and 60 °C for 1 min. Each sample was tested in triplicate and *gapdh* was used as an internal control gene. Relative expression levels were analysed by the $2^{-\Delta\Delta Ct}$ method.

Western blot: A total of 200 MII oocytes from 24 mice were lysed in 1 x SDS sample buffer containing 1 x protease inhibitor Cocktail (cwbiotech) on ice for 20 min. They were boiled for 5 min at 95 °C, then subjected to 12 % SDS-PAGE and the separated proteins were transferred to polyvinylidene fluoride (PVDF) membrane. The membrane was blocked for 2 h with 5 % nonfat milk in TBST and then probed with primary antibodies for 2 h at room temperature (anti-p-MAPK antibody, 1:500; anti-Bcl-2 antibody, 1:1000; anti-Bax antibody, 1:1000; anti-LC3 antibody, 1:1000; anti-Atg12 antibody, 1:500; anti-α-tubulin antibody, 1:1000; and anti-β-actin antibody, 1:1000). After washing three times with TBST (10 min each), membranes were incubated for 1 h with the appropriate HRP-conjugated secondary antibodies (1:1000). Three washes later, the protein bands were visualised using BeyoECL Plus (Thermo Fisher Scientific), and the signals were acquired by Tanon 5500. The images were quantified using ImageJ software.

Statistical analysis: At least 50 oocytes were analysed for each experiment. For each treatment, at least three biological replicates were performed and data are presented as the mean ± standard error of the mean (SEM). Statistical comparisons were performed using the GraphPad Prism software followed by Student's unpaired two-tailed t-test and two-way ANOVA. Statistical significance was set at P value: *<0.05, **<0.001, ***<0.0005, ****<0.0001.

Results

Glyphosate composition analysis: The chemical composition of glyphosate was analysed before the start of the experiment by Ultra Performance Liquid Chromatography/Quadrupole-Time-of-Flight-Mass Spectrometry (UPLC/Q-TOF-MS). Specific results from this analysis were not reported.

Glyphosate treatment reduced the GVBD and PBE in mouse oocytes: To test the effect of glyphosate on the mouse oocytes maturation, the oocytes were cultured in culture medium supplemented with increasing concentrations of glyphosate (50, 100, 200 or 500 μM). Typical images of exposure to glyphosate on GVBD and PBE are shown in Fig. 2. After treatment with glyphosate, GVBD (Fig. 2A and B) and PBE (Fig. 2C and D) were significantly decreased in the 200 mM and 500 mM groups, while there was no significant variation in the 50 μM and 100 μM treatment groups. Hence, the 500 μM glyphosate treatment was adopted for subsequent experiments. These observations were considered to show that glyphosate exposure decreased mouse oocyte developmental competence.

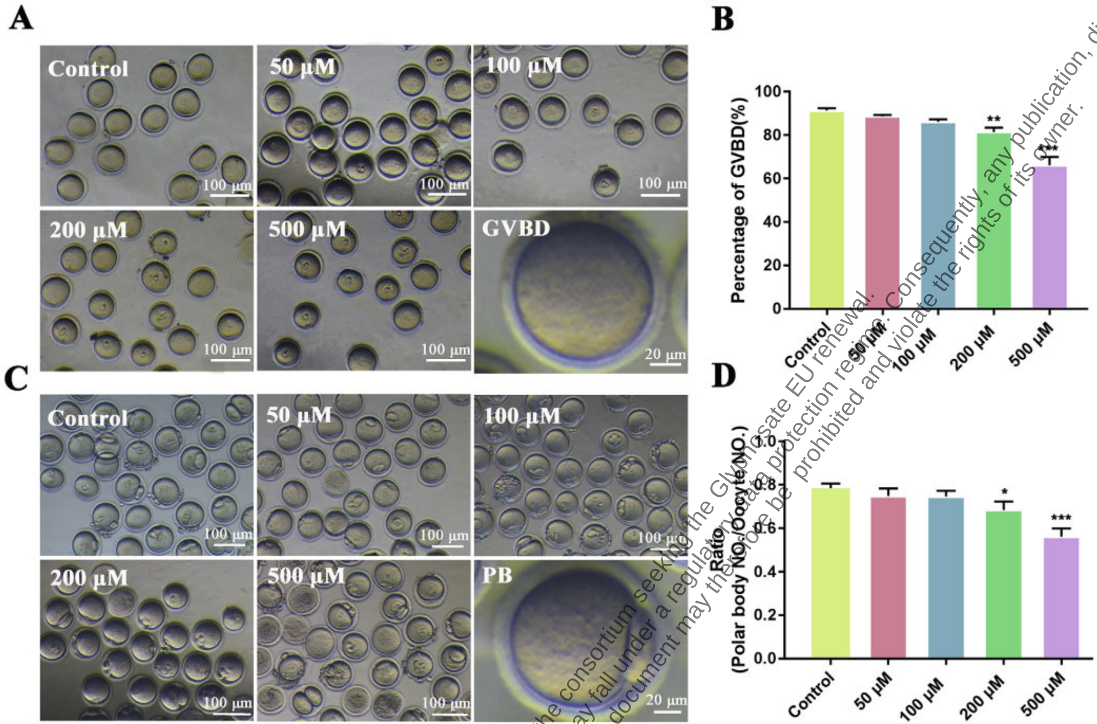

Fig. 2. Effects of glyphosate on GVBD and PBE in mouse oocytes. (A) Representative images of mouse oocytes after exposure to different concentrations of glyphosate for 2 h. (B) GVBD rates of different groups after 2 h of treatment. The data are expressed as the mean ± SEM. (C) Representative images of mouse oocytes after exposure to different concentrations of glyphosate for 14 h. (D) Quantification of the presence of PBE in control and treatment oocytes. The data are expressed as the mean ± SEM.

Glyphosate treatment increased ROS generation and DNA damage in mouse oocytes: It was tested whether defects observed in glyphosate-exposed mouse oocytes were mediated by oxidative stress. As shown in Fig. 3A and B, the fluorescence intensity of DCFH-DA was significantly higher in the 500 µM glyphosate treatment group than in the control oocytes. The levels of sod2 and gpx mRNA expression were significantly increased in glyphosate-exposed oocytes when compared with the control group (Control: sod2: 1.005 ± 0.066, gpx: 1.003 ± 0.052; 500 µM: sod2: 1.702 ± 0.148, gpx: 1.545 ± 0.181); the expression of *cat* mRNA was also increased (Control: 1.001 ± 0.036; 500 µM: 1.241 ± 0.111). These results suggested that glyphosate administration enhanced ROS production. As described above, glyphosate is cytotoxic to oocytes. As shown in Fig. 3D, there were no significant DSB foci in the control oocytes; however, there was a dense mass of γ-H2AX foci associated with chromatin in glyphosate-exposed oocytes. As shown in Fig. 3E, the fluorescence intensity of γ-H2AX also significantly increased after glyphosate treatment compared to that in the control group. These results were considered to indicate that glyphosate treatment results in DNA damage in mouse oocytes.

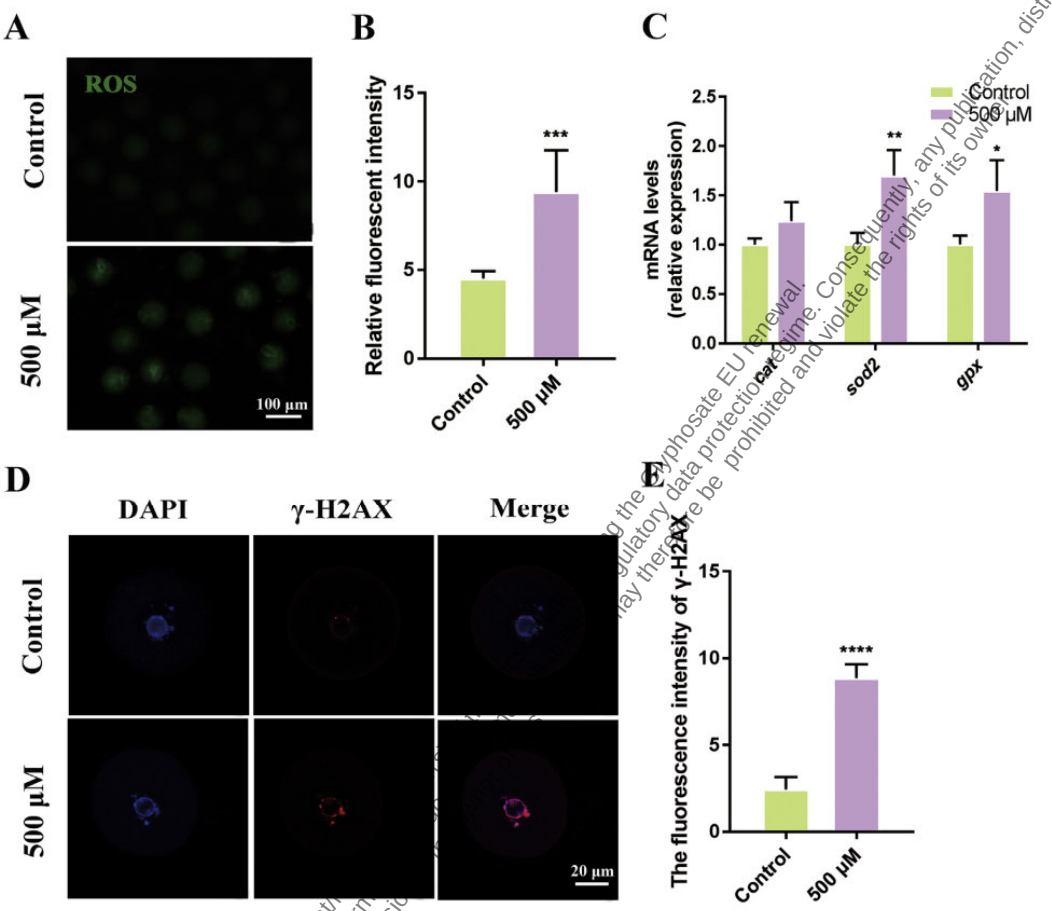

Fig. 3. Effects of glyphosate on ROS generation and DNA damage in mouse oocytes. (A) Representative images of DCFH-DA fluorescence in control and glyphosate-exposed mouse oocytes. (B) Quantitative analysis of ROS fluorescence intensity in control and glyphosate-exposed groups. The data are expressed as the mean ± SEM. (C) Relative expression levels of oxidative stress-related genes were examined by qRT-PCR. The data are expressed as the mean ± SEM. (D) Representative images of control and glyphosate-treated oocytes exhibiting γ-H2AX immunostaining. (E) The γ-H2AX fluorescence intensity obviously increased after glyphosate treatment. The data are presented as the mean ± SEM.

Glyphosate treatment disturbs spindle morphology in mouse oocytes: o investigate whether the oocytes with glyphosate treatment showed defects in spindle positioning and chromosome scattering, MII oocytes were assessed by immunocytochemical staining with anti-α-tubulin antibody and DAPI. In contrast to oocytes from the control group, which presented a normal spindle appearance and well-aligned chromosomes at the equatorial plate, the glyphosate-exposed group showed misaligned chromosomes and abnormal spindle morphology(Fig. 4A). The rate of abnormal spindles in the glyphosate treatment group was also increased (Control: 9.333 ± 0.491%; 500 µM: 15.767 ± 1.369%). as shown in Fig. 4B. The effect of glyphosate on the expression levels of spindle assembly regulatory protein was also assessed. In Fig. 4C and D, Western blots revealed that the level of p-MAPK protein was significantly reduced after 500 µM glyphosate treatment (Control: 0.856 ± 0.053; 500 µM: 0.517 ± 0.070). These results were considered to suggest that glyphosate treatment disturbs spindle morphology in mouse oocytes.

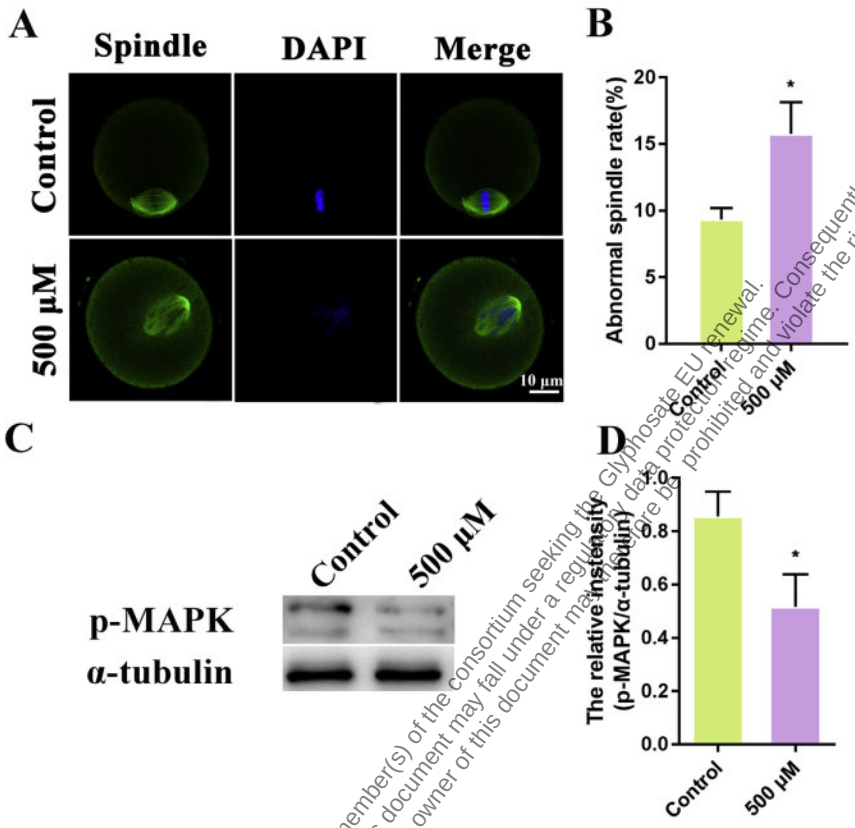

Fig. 4. Effects of glyphosate on spindle morphology and chromosome alignment in mouse oocytes. (A) Representative confocal images of spindle morphology in control and glyphosate exposed groups. (B) Percentage of cells exhibiting abnormal spindle/chromosome morphology. The data are expressed as the mean ± SEM. (C) The expression level of p-MAPK protein in oocytes from different groups was analysed by Western blot analysis. (D) The relative intensity of p-MAPK protein expression (p-MAPK/α-tubulin) was significantly reduced after treatment with 500 μM glyphosate. The data are expressed as the mean ± SEM.

Glyphosate treatment resulted in mitochondrial injury in mouse oocytes: A homogeneous distribution of mitochondria was present in the control group,but an aggregated distribution was seen in the glyphosate-exposed group by staining with Mito Tracker Red (Fig. 5A). Alterations in MMP of mouse oocytes from different groups were evaluated by staining with JC-1 (Fig. 5B). As shown in Fig. 5C, the result illustrated that the MMP was significantly lower in the glyphosate-exposed group compared with the control group (Control: 1.871 ± 0.082; 500 μM: 4.517 ± 0.155). Based on these data, glyphosate treatment was considered to interfere with mitochondrial function in mouse oocytes.

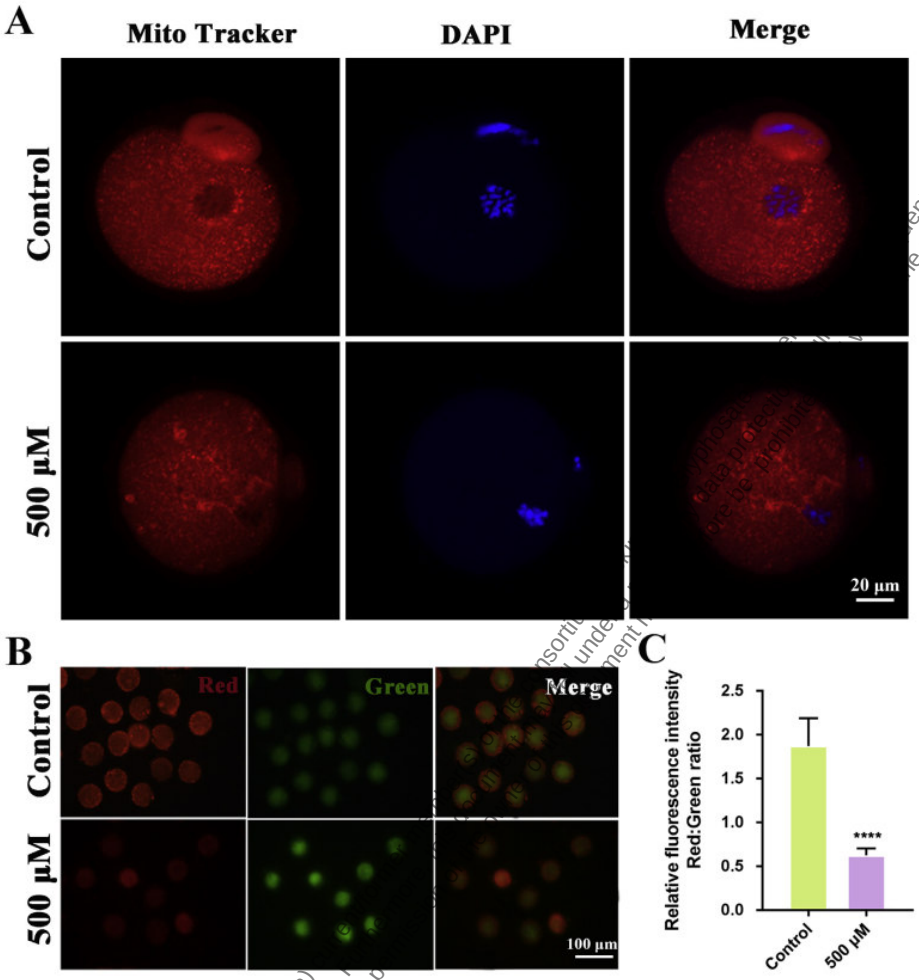

Fig. 5. Glyphosate treatment results in mitochondrial injury in mouse oocytes. (A) Representative images of mitochondrial distribution in control and glyphosate-treated oocytes by staining with MitoTracker Red. (B) Representative images of MMP in mouse oocytes from different groups stained with JC-1. (C) MMP levels (red/green fluorescence intensity) in glyphosate-exposed oocytes was significantly lower than that in the control group. The data are presented as the mean ± SEM. (For interpretation of the references to colour in this figure legend, the reader is referred to the Web version of this article.)

Glyphosate treatment induced early apoptosis and autophagy in mouse oocytes: Annexin-V staining was conducted to identify whether early apoptosis occurred in glyphosate-treated oocytes. In the control group, Annexin-V signals were detected only in the zona pellucida, whereas the treatment group had a clear green signal in the membrane and zona pellucida Fig. 6A). In Fig. 6B, the apoptotic fluorescence intensity of oocytes was notably higher in the treatment group than in the controls. Apoptosis-related protein expression levels were also assayed via As shown in Fig. 6G and H, Western blot analysis, which showed that the expression of Bcl-2 protein decreased and the expression of Bax protein increased after exposure to 500 μM glyphosate (Control: Bcl-2: 0.645 ± 0.009, Bax: 0.427 ± 0.020; 500 μM: Bcl-2: 0.549 ± 0.011, Bax: 0.556 ± 0.018). To confirm this result, the mRNA expression levels of apoptosis-related genes were tested by qRT-PCR. The qRT-PCR results were consistent with the Western blot results. Together, these results were considered to indicate that glyphosate induced early apoptosis in mouse oocytes. Whether autophagy had occurred in glyphosate-treated oocytes was assessed by LC3 immunofluorescent staining; As shown in Fig. 6D and E, the fluorescence intensity was significantly higher in the 500 μM glyphosate treatment group than in the oocytes from the control group. The mRNA expression levels of autophagy-related genes were also assessed by qRT-PCR and showed an increasing trend (Control: *lc3*: 0.860 ± 0.013, *atg14*: 1.024 ± 0.149, *mtor*: 0.847 ± 0.171; 500 μM: *lc3*: 1.591 ± 0.109, *atg14*: 1.800 ± 0.139, *mtor*: 1.268 ± 0.242 (Fig. 6F). Western blot analysis showed that the expression of LC3 and Atg12 protein increased after exposure to 500 μM glyphosate (Control: LC3: 0.280 ± 0.021, Atg12: 0.435 ± 0.007; 500 μM: LC3:0.504 ± 0.030, Atg12: 0.580 ± 0.016). Together, these results were considered to indicate that glyphosate induced

autophagy in mouse oocytes.

Discussion

In recent years, numerous studies have demonstrated the damaging effects caused by glyphosate in various organisms using different test systems. However, few studies evaluated the reproductive effects of glyphosate on female mammals. Therefore, we investigated the toxic effects of glyphosate on mouse oocyte maturation *in vitro*. Based on the experimental results, we believe that glyphosate contributed to the destruction of oocyte development . Germinal vesicle breakdown and the first polar body extrusion are markers of oocyte nuclear maturation. Our experimental results indicated that mouse oocytes exposed to glyphosate in vitro experienced a decrease in the proportion of GVBD and PBE. The decrease in the ratio of GVBD and PBE indicates that the growth and developmental ability of the oocyte is destroyed. Reactive oxygen species are excessively generated when cells are subjected to various noxious stimuli, and the oxidative system and the antioxidant system are out of balance, resulting in cell damage. Therefore, we examined the level of ROS in mouse oocytes after glyphosate exposure, and our results showed that ROS levels were increased. To survive, the expression of the antioxidant enzyme genes is increases increased.

The mRNA expression levels of sod2, cat and gpx were significantly increased in mouse oocytes exposed to glyphosate. Mouse oocytes exposed to glyphosate produced excessive ROS, which in turn affected their growth and development. Oocytes are rich in mitochondria. These mitochondria play a leading role in cell metabolism. The changes in their morphology, quantity, distribution and function are closely related to cell metabolism, proliferation and differentiation. Mitochondria are mostly uniformly distributed in the cytoplasm in oocytes with higher developmental potential, while they are aggregated in oocytes with lower developmental potential. A lack of mitochondrial rearrangement in the cytoplasm is a marker of immature cytoplasm. Our results showed that mouse oocytes exposed to glyphosate had aggregated mitochondria and a decrease in membrane potential. These findings indicated that glyphosate destroyed the function of the mitochondria in oocytes. The cytoskeleton plays an important supporting role in the oocyte maturation process. The morphology and kinetic changes of the spindle may reflect the quality of oocytes, and its integrity determines the correctness of chromosome segregation. Abnormalities in spindle morphology will lead to meiosis and fertilisation failure. MAPK is a regulated protein involved in microtubule assembly and mitotic spindle assembly. The experimental results showed that after glyphosate exposure, the expression level of p-MAPK protein in mouse oocytes was decreased. So, we proposed that glyphosate affected formation of the spindle by altering the level of p-MAPK, which in turn resulted in a reduction in the rate of mouse oocyte maturation. Excessive accumulation of ROS products has an adverse effect on lipids, proteins, and DNA. In addition, ROS damages the sugarphosphate back-bone of DNA, resulting in single- and double-strand breaks. DNA damages in cells primarily originate from oxidative stress. g-H2AX produced by phosphorylation of H2AX can be used as a biomarker to clearly reflect the extent of DNA damage and repair. Oocytes exposed to glyphosate showed an increase in g-H2AX foci, showing that glyphosate could destroy DNA integrity and produce cytotoxicity in oocytes. Oxidative stress is often associated with apoptosis and autophagy. Therefore, we first detected apoptosis in oocytes by Annexin-V staining. Our experimental results showed that the apoptotic fluorescence intensity of oocytes was increased after glyphosate exposure. The Bcl-2 gene is an inhibitor of apoptosis, and Bax is a pro-apoptotic gene that plays an important role in regulating apoptosis. In the mitochondrial mediated apoptosis pathway, abnormal intracellular signals lead to the activation of Bax, inhibit the expression of Bcl-2, induce mitochondria release of cytochrome c, form apoptotic bodies or initiate caspase cascade activation, and then lead to the occurrence of apoptosis. Western blot analysis and qRT-PCR showed that the expression of Bcl-2 was decreased and the expression of Bax was increased in glyphosate-treated oocytes. Although there was no significant difference in caspase3 mRNA expression, there was an increasing trend after exposure to glyphosate. Autophagy mainly includes phagophore, autophagy formation, autophagosome formation and degradation. The combination of PI3K complex and Atg14 is involved in the formation of phagophore. Atg gene regulates the formation of autophagosomes by forming Atg12-Atg5 and LC3-II complexes. Microtubule associated light chain protein (LC3) is present in autophagosomes; therefore, the LC3 protein is widely used as a marker for autophagosomes. Mammalian target of rapamycin, mTOR, also plays a role in the autophagy pathway. Our results showed that the fluorescence intensity of LC3 was significantly increased, and the expression levels of autophagy-related proteins and genes were increased in the glyphosate treatment group. We considered that oocytes exposed to glyphosate-induced ROS, which could further activate autophagy and early apoptosis, could lead to a decrease in oocyte quality.

Conclusion

In summary, glyphosate exposure was considered to have caused a block in mouse oocyte development, spindle assembly disruption and chromosome scattered distribution, mitochondrial aggregation and membrane potential reduction, DNA damage, and increased oxidative stress levels, which then led to cellular apoptosis and autophagy. These results were considered to provide evidence for the toxic effects of glyphosate on reproductive systems.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In vitro intracellular changes in Kunming mice oocytes were evaluated after being cultured in medium

supplemented with 500 µM glyphosate. Findings included: decreased germinal vesicle breakdown, decreased first polar body extrusion, increased mRNA expression of anti-oxidant enzyme-related genes, abnormal spindle morphology, increased DNA double strand breaks, aggregated mitochondria, decreased mitochondrial membrane potential, increased protein expression of apoptosis factors, increased mRNA expression of apoptosis related genes and decreased autophagy-related genes.

No dose-response could be determined as only one concentration was tested, far in excess of that considered biologically relevant. Whilst some evaluations were conducted on oocytes harvested from a wider data set of 24 mice (protein expression levels of apoptosis factors by Western blot analysis), a number of the assessments were conducted on oocytes from just 12 mice (mRNA expression of oxidative stress-related, apoptosis-related and autophagy-related genes) or 6 mice (mitochondrial staining, measurement of mitochondrial membrane potential). This narrow source of oocytes limits the robustness of certain conclusions. Furthermore, there are insufficient details reported in the methods to establish whether mice were of the same age before oocyte harvesting or the purity of the glyphosate tested.
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because of the poor characterisation of the glyphosate tested, no cytotoxicity testing, the lack of a positive control and insufficient dose-response characterisation at biologically relevant doses.

2. Full summary of the study according to OECD format

Glyphosate has been suggested to be an endocrine disrupting chemical capable of disrupting male reproduction. There are conflicting data, however, with studies reporting effects from exposure to either glyphosate alone or to herbicide formulations, making comparisons difficult. Rat testis histopathology and androgen function following two weeks exposure to either glyphosate at 2.5 and 25 mg/kg bw/day (5x and 50x Acceptable Daily Intake, ADI, respectively), or equivalent high dose of glyphosate in a herbicide formulation; Glyfonova, were assessed.

Materials and methods

Chemicals - Glyphosate (purity ≥ 96 %) was purchased from Sigma-Aldrich, St Louis, USA.

Animals - Four–week old male Sprague-Dawley rats were randomly caged in pairs and acclimatised for 7 days. Cages were subsequently distributed into four exposure groups based on animal weight, but following exposure only one animal per cage was used for analyses. Ten animals per dose group were treated with

glyphosate orally by gavage at 2.5 and 25 mg/kg bw. Water was used as the control. After 2 weeks of exposure, the animals were decapitated under CO_2/O_2 sedation and the testes collected. From each of 10 males per dose group, one testis, selected at random, was snap frozen in liquid nitrogen and the other was fixed in 10 % formalin.

Testosterone assay - One half of each testis was used for hormone extraction. The testes were cut into two equally sized pieces. After removal of the testis cap the inner tissue (seminiferous tubules and interstitial cells) was transferred immediately to a glass vial containing 0.5 mL sterile water and reweighed to determine total tissue weight per sample. Subsequently, 2.5 mL heptane was added and the sample homogenised by manual disruption and then frozen solid. The heptane fraction was transferred and the process repeated to yield a second 2.5 mL heptane fraction that was pooled together with the first fraction. The extracts were dried under nitrogen. Before hormone analyses, the dry extracts were dissolved in EIA buffer at 4 °C overnight, then vortexed and placed in a 42 °C water bath for 10 minutes. Intra-testicular testosterone assays were performed using the Testosterone ELISA kit according to the manufacturer's instructions. Reads were obtained using 96-well plates and absorbance read at 405 nm using a microplate reader. Each sample was assayed in duplicates and result means presented as pg testosterone/g testis.

Histology - Testes were fixed in 10 % formalin, processed for paraffin embedding and sectioned at 5 µm for histological assessments. Hematoxylin & Eosin (H&E) staining was performed following standard protocols.

Immunohistochemistry - Immunohistochemistry with peroxidase was carried out on sections of formalin-fixed testes. Sections were dewaxed in petroleum and rehydrated by immersion in ethanol solutions and finally water. Antigen retrieval was carried out in 0.01 M citrate buffer (pH 6) in a microwave and then allowed to cool at room temperature. Samples were washed in PBS and blocked with 1 % bovine serum albumin (BSA) and then incubated overnight at 4 °C with primary antibody. The following day, samples were washed in PBS, blocked with 3 % H_2O_2 for 10 minutes and again washed in PBS. The samples were incubated with EnVision+System (Dako) for 30 minutes, washed, then with Liquid DAB+System (Dako) for 15 minutes and washed again. To visualize all cell nuclei, sections were counterstained with Meyers' hematoxylin. Following washing and rehydration, samples were mounted with Eukitt. The primary antibody used was against the Androgen receptor.

Immunofluorescence – Five µm sections (4/group) were dewaxed in petroleum and washed in ethanol and dehydrated. Antigen retrieval was done by heat treatment in Tris-EDTA buffer (pH 9) and then cooled at room temp before washing in PBS and blocking in 5 % bovine serum albumin (BSA). The samples were incubated with primary antibodies overnight at 4 °C. The next day, slides were brought to room temperature and incubated with secondary antibodies for 1 hour in the dark. Samples were then counterstained with 4,6-diamidino-2-phenylindole (DAPI). The primary antibodies were goat anti-HSD3β, rabbit anti-DDX4, goat anti-CYP11A1 and rabbit anti-STAR. Secondary antibodies were donkey anti-goat AlexaFluor-488 and donkey anti-rabbit AlexaFluor-568.

RNA extraction, cDNA synthesis and quantitative RT-PCR - Total RNA was extracted from a ~100 mg cross-sectional piece from each testis (n=10/group), of which 500 ng RNA was used for each cDNA synthesis. TaqMan Gene Expression Assays were Ar (Rn00560747), Ddx4 (Rn01489814), Cyp11a1, Cyp17a1, Insl3 (Rn00586632), Pcna (Rn01514538), Star and Hsd3b1 (Rn017747410). RT-qPCR assays were run on a QuantStudio 7 Flex Real-Time PCR System in a 384-well format using 3 µL diluted (1:20) cDNA as template in each 20 µL reaction. Relative transcript abundance was calculated by the comparative Ct-method with the geometric mean of the reference genes Sdha (Rn00590475) and Rpl13a (Rn00821946).

Apoptosis - One section per testis (n=5/group) was stained with terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL, Apoptag®Peroxidase in Situ Apoptosis Detection Kit) according to the manufacturer's instructions with one exception i.e. pre-dilution (1:80) of the TdT enzyme in MilliQ water before dilution with reaction buffer. Color was developed for 15 minutes using DAB+substrate. Lastly, the nuclei were stained using Mayer Hematoxylin prior to mounting using Eukitt. All positively stained cells

within the seminiferous tubules on a cross-section were counted. Cells that were clearly stained as a result of cell division rather than apoptosis were excluded, as were stained cells at the outer border of the tissue sections. The relative percentage of seminiferous epithelium to whole testis was calculated using a 15 point-grid count on three separate fields of view from each sample. Second, whole testis section areas were calculated in Adobe Photoshop CC 2017 using the measurement tool. Third, apoptotic cells were defined relative to percentage seminiferous epithelium to whole section. Data and statistical analyses are presented as number of apoptotic cells per seminiferous tubuli area.

Statistical analysis - Data were tested for normal distribution and homogeneity of variance and logarithmic transformation was applied if required. ANOVA with Dunnett's post-test was applied and $p<0.05$ was considered statistically significant. Statistical software GraphPad Prism 5 was used for analysis.

Results

Testosterone levels - No statistically significant increase in testicular testosterone levels was observed in rats treated orally at 2.5 and 25 mg/kg bw/day for 2 weeks.

Quantitative gene and protein expression analysis - In the testis from animals orally exposed to glyphosate at 2.5 or 25 mg/kg bw/day for 2 weeks no significant differences in gene expression were observed for the Leydig cell specific genes Cyp11a1, Cyp17a1, Insl3, Hsd3β1 and Star and the somatic marker gene Ar or germ cell marker gene Ddx4.

Testis histopathology - No adverse histopathology in any of the glyphosate exposed groups was observed when compared with controls. The seminiferous tubules were intact and displayed active spermatogenesis with comparable spermatogenic cycling between examined specimens (qualitative assessment). Neither were there any differences between exposed and control animals with regard to missing germ cell layers or multinucleated germ cells. The interstitial space was comparable between glyphosate treated groups and controls.

Qualitative protein expression analysis - The Leydig cell-specific steroidogenesis factors CYP11A1 and STAR were both expressed at comparative levels between the glyphosate treated animals and the controls. Also no difference in expression and distribution was noted between glyphosate treated groups and controls for the steroidogenic enzyme HSD3B1 and the germ cell-specific factor DDX4.

Apoptosis - The number of apoptotic cells was comparable between control testes and all glyphosate treated groups (5 per group).

Discussion and conclusions

Glyphosate at 2.5 mg/kg bw/day (5-fold ADI) and 25 mg/kg bw/day (50-fold ADI) did not show significant effects on intra-testicular testosterone levels, testicular gene and protein expression, testicular histopathology and apoptosis in the testes of rats treated orally for 2 weeks. This suggests that the active compound glyphosate may not contribute to previously reported endocrine disrupting effects, but rather other constituents in the commercial formulated products. This is in agreement with conclusions from the most recent expert opinion review on glyphosate commissioned by the European Food Safety Authority which conclude that there is no evidence of endocrine mode of action of glyphosate.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The effects of glyphosate on intra-testicular testosterone levels, expression of Leydig cell-specific genes Cyp11a1, Cyp17a1, Insl3, Hsd3β1 and Star and expression of somatic marker gene Ar or germ cell marker gene Ddx4, expression of Leydig cell-specific steroidogenesis factors CYP11A1 and STAR, testicular histopathology and apoptosis were investigated in male rats treated orally at 0, 2.5 and 25 mg/kg bw/day for 2 weeks. No effects were found on either of the testicular parameters tested

suggesting that glyphosate does not contribute to endocrine disrupting effects of the male reproductive system.
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because only two dose levels were used to explore the dose-effect relationship for the endpoints assessed.

2. Full summary of the study according to OECD format

The current study represents the first phase of a long-term investigation of glyphosate-based herbicides (GBHs) that we are conducting over 5 years. In this paper, the study design, the first evaluation of *in vivo* parameters and the determination of glyphosate and its major metabolite aminomethylphosphonic acid (AMPA) in urine is presented.

Materials and methods

Chemicals - Glyphosate (purity of > 99.5 %), Pestanal™ analytical standard purchased from Sigma-Aldrich (Milan, Italy). The representative formulated product, Roundup Bioflow (MON 52276, containing 360 g/L of glyphosate acid in the form of 480 g/L isopropylamine salt of glyphosate (41.5 %), water (42.5 %) and surfactant (16 %)) was purchased from Consorzio Agrario dell'Emilia, Bologna, Italy.

Animals - Male and female SD rats were obtained from the colony used at the Cesare Maltoni Cancer Research Center laboratories of the Ramazzini Institute (CMCRC/RI). The animal room conditions were 22 ± 3 °C and 50 ± 20% relative humidity and a light/dark cycle of 12 hours. During the experiment the animals received standard pellet feed and tap water *ad libitum*.

Experimental design - Each of 8 virgin female SD rats (17 weeks old, 270-315 g) per dose group was placed individually in a polycarbonate cage with a single male rat of the same age and strain until evidence of copulation. Gestational day (GD) 0 was defined as the day on which sperm was found in vaginal smears. After mating, matched females were housed separately during gestation and delivery and pups were housed with the dams until weaning. The day on which parturition was completed was designated as lactating day (LD) 0 for the dam and postnatal day (PND) 0 for the offspring. On PND 28, the offspring were weaned and identified by ear punch. Sequentially, they were allocated in the same treatment group of their mother to obtain 18 animals (8 for the 6–week cohort and 10 for the 13–week cohort) per sex and for each dose group. No more than 2 males and 2 females from the same litter were included in the same cohort/treatment group. Altogether, 54 males and 54 females were enrolled in the post-weaning treatment phase. Rats were treated with glyphosate and MON 52276 at 1.75 mg glyphosate acid eq./kg bw/day in the drinking water. One group received only tap water as control. After weaning, until the end of the experiment (PND 73 ± 2 or 125 ± 2), glyphosate and MON 52276 were administered in the drinking water to F1 animals on the basis of the average body weight and average water consumption per sex and per experimental group. Males and females were considered separately because of their difference in weight gain, body weight and water consumption. Animals were checked 3 times daily on working days and 2 times daily on Sundays and non-working days. Clinical signs were checked before the start of the treatment, and at least every two days until the end of the experiment. The body weight of the dams was recorded on GD 0, 3, 6 and then daily

during gestation until parturition. During lactation, the body weight of the dams was recorded at LD 1, 4, 7, 10, 13, 16, 19, 21 and 25 and the body weight of the pups by sex and litter was determined on PND 1, 4, 7, 10, 13, 16, 19, 21 and 25. After weaning, body weight was measured twice a week until PND 73 ± 2, then weekly until PND 125 ± 2 and before terminal sacrifice. The mean individual body weights were calculated for each group and sex. Feed and water consumption of the dams were recorded twice weekly on GD 0, 3, 6, 9, 12, 15, 18, 21, and during lactation on LD 1, 4, 7, 10, 13, 16, 19, 21, 25 and 28. After weaning the daily feed and water consumption per cage were measured twice a week, until PND 73 ± 2, then weekly until PND 125 ± 2. The mean individual feed and water consumption were calculated for each group and sex. The day before terminal sacrifice, all the animals were placed individually in metabolic cages and starved for around 16 hours during which the animals had free access to water alone or to the test compound solutions. In the morning of the following day, samples of at least 5 mL of urine collected from each animal were transferred to labelled tubes for analysis of glyphosate and AMPA. Samples from 3 dams/group and from 5 rats/sex/group belonging to the 6–week and 13–week cohorts were used for analysis.

Analysis of glyphosate and AMPA in urine - Analysis of glyphosate and AMPA in drinking water, feed and urine were performed by Neotron Laboratories. The specification and results are maintained in the experimental documentation. Analysis was performed using LC-MS/MS. The limit of quantification (LOQ) for glyphosate and AMPA was 0.10 µg/L in water, 50 µg/kg in feed, and 1 µg/L in urine.

Statistical analysis - Means ± standard deviations (SD), were calculated for continuous variables. For body weight, water and feed consumption over time multilevel mixed-effect linear regression models were used, to control for within subject correlation across time also considering the litter effect during the lactation period. Analysis of variance and Dunnett's test (when applicable) were also performed to compare body weight gain in different periods and consumption of food and water as mean consumption in several periods. All tests were two tailed with results considered as statistically significant if $p<0.05$. Statistical analyses were performed by using STATA version10.

Results

Mortality, body weight, water and food consumption, clinical signs and litter data - All 24 dams and 108 rats from the 6–week and 13–week cohorts survived until sacrifice. Body weight and body weight gain of the dams during gestation and lactation were not statistically different among groups. Post-weaning body weight of female and male offspring was homogeneous and no statistically significant differences in body weight gain were observed among groups. Water and feed consumption during gestation and lactation were not different across groups. Litter sizes were fully comparable among groups, with mean number of live pups of 13.6 (range 10–16) in the control group, 13.3 (range 11–17) in the glyphosate group and 13.9 (range 11–16) in the MON 52276 group. Post weaning water and feed consumption were not affected by treatment. There was no clinical evidence of alterations in activity or behavior, reflexes, eyes or skin, respiratory, gastrointestinal, genitourinary and cardiovascular systems.

Analysis of glyphosate and AMPA in urine – The results of the analysis are presented in the Table below.

Table: Glyphosate and AMPA concentration in urine. Results are reported as mean ± standard deviations

		Dams		Offspring (6-week cohort)		Offspring (13-week cohort)	
	Treatment	Glyphosate (mg/kg)	AMPA (mg/kg)	Glyphosate (mg/kg)	AMPA (mg/kg)	Glyphosate (mg/kg)	AMPA (mg/kg)
Male	Control			0.012 ± 0.010	0.003 ± 0.003	0.011 ± 0.010	0.006 ± 0.004
	Glyphosate	–	–	0.938 ± 0.414	0.014 ± 0.007	1.684 ± 0.768	0.023 ± 0.012
	Roundup			1.174 ± 0.439	0.011 ± 0.005	2.280 ± 1.520	0.027 ± 0.016
Female	Control	0.009 ± 0.001	0.006 ± 0.002	0.013 ± 0.007	0.005 ± 0.001	0.008 ± 0.005	0.003 ± 0.005
	Glyphosate	0.480 ± 0.010	0.024 ± 0.002	0.938 ± 0.377	0.016 ± 0.010	1.354 ± 0.359	0.013 ± 0.006
	Roundup	0.700 ± 0.106	0.024 ± 0.001	0.910 ± 0.383	0.018 ± 0.007	1.524 ± 0.585	0.021 ± 0.007

The urinary concentrations of glyphosate and AMPA of rats treated with glyphosate at 1.75 mg/kg bw/day were comparable to those observed in rats treated with MON52276 at 1.75 mg glyphosate acid eq./kg bw/day, despite the limited sample size and the large standard deviations. Glyphosate and AMPA urinary levels were all below or close to the LOQ of 0.001 mg/kg in the control group. In the treated rats, the majority of glyphosate was excreted unchanged, with urinary levels about 100-fold higher than that of AMPA. For example, the mean urinary levels of glyphosate were 1.354 and 1.524 mg/kg bw in glyphosate and MON 52276 treated females in the 13–week cohort, respectively, while the corresponding AMPA levels were 0.013 and 0.021 mg/kg bw. In glyphosate and MON 52276 treated rats, a time-dependent increase in the mean urinary concentration of glyphosate was observed. In glyphosate and MON 52276 treated males, an increase of approximately 2-fold was observed of the mean urinary concentration of glyphosate in the 13–week cohort when compared to the 6–week cohort. In glyphosate treated females, the 6–week cohort showed a 2-fold higher mean urinary concentration of glyphosate than the dams after weaning, while the 13–week cohort showed a 1.5-fold increase compared to the 6–week cohort. In the MON 52276 group, the increase was less steep, but the time-dependent pattern was still evident. In glyphosate and MON 52276 treated rats, the levels of AMPA were comparable at the different time points in both males and females. Large variations were observed of the AMPA concentrations in urine, in particular those close to the LOQ as in the control groups.

Discussion

Survival, body weights, food and water consumption of rats were not affected by the treatment with glyphosate or MON 52276. No clinical changes were observed in the animals of the dosed groups. Overall, oral treatment of glyphosate and MON 52276 via the drinking water seemed to be well tolerated. Exposure to glyphosate and MON 52276 led to comparable concentrations of glyphosate and AMPA in urine, indicating that systemic exposure does occur at the selected exposure level of 1.75 mg/kg bw/day, corresponding to the US ADI. The bioavailability of glyphosate in this study is also supported by the evident increase of glyphosate concentration in urine in relation to the length of treatment. The adjuvants and the other substances present in MON 52276 did not seem to exert a major effect on the absorption and excretion of glyphosate, even though mean values of glyphosate seem to be somewhat higher in the formulation treated group. The levels in urine were also comparable between the two sexes, although a consistent inter-individual variability was observed. In rats, glyphosate in urine appears to be the most accurate biomarker of exposure to glyphosate based herbicides (GBHs). The results from this study confirm previous evidence that in rodents most of the administered dose of glyphosate (98 %) is excreted as unchanged parent compound, whereas the metabolite AMPA in urine is at around 0.2–0.3 % of the administered dose. Furthermore, with the level of exposure to glyphosate used in this pilot study, AMPA urinary values of treated animals (0.011–0.027 mg/kg) were already close to the LOQ (0.001 mg/kg) which might limit the reliability of the data. Glyphosate concentrations in urine of treated animals (0.480–2.280 mg/kg) were found to be 100-fold higher than the AMPA concentrations and at least 500-fold higher than the LOQ. Therefore, in order to assess exposure to glyphosate in rats, in particular at doses that are equal or lower than 1.75 mg/kg bw/day, glyphosate appears to be the biomarker of choice. The presence of negligible levels of glyphosate (0.003–0.013 mg/kg) in some of the urine samples of the control groups might reflect an ubiquitous environmental contamination at ultra-low doses of glyphosate, which is consistent with previous reports from other authors. As the current LOQ of glyphosate in HPLC for pelleted animal feed is 0.050 mg/kg, this represents a technical limiting factor for the testing ultra-low doses of glyphosate.

Conclusion

A pilot study was performed on the health effects of glyphosate and its formulation Roundup Bioflow (MON 52276) administered orally to rats at the US ADI of 1.75 mg/kg bw/day. Treatment with either glyphosate or MON 52276 seemed to be overall well tolerated, consistent with previous experiments performed by the US NTP. Both glyphosate and MON 52276 exposure led to comparable urinary concentrations of glyphosate and AMPA with an increasing excretion of glyphosate in urine with duration of treatment. This indicates the systemic bioavailability of glyphosate and a possible mechanism of bioaccumulaton. The adjuvants and the other substances present in the formulation did not seem to exert a major effect on the absorption and excretion of glyphosate when administered orally. The results of this

study confirm that, in rodents, glyphosate is a much more relevant biomarker in urine than AMPA, in particular at doses that are equal or lower than 1.75 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this study the general toxicity of glyphosate was compared against that of its reference formulation MON 52276 in pregnant rats and their progeny. Also the urinary excretion of glyphosate and AMPA was investigated. The test compounds were administered via the drinking water resulting in a daily dose of 1.75 mg glyphosate acid eq./ kg bw. The endpoints investigated were mortality, body weight, water and food consumption, and clinical signs in dams and offspring and litter data. There was no mortality and no statistically significant differences were observed among control, glyphosate, and MON 52276 groups in any of the endpoints investigated. Urinary concentrations of glyphosate and AMPA of rats treated with glyphosate at 1.75 mg/kg bw/day were comparable to those observed in rats treated with MON 52276 at 1.75 mg glyphosate acid eq. /kg bw/day. This indicates that the co-formulants in this glyphosate formulation have little influence on the oral bioavailability of glyphosate. In the treated rats, the majority of glyphosate was excreted in urine unchanged at levels of about 100-fold higher than that of AMPA and the mean urinary concentration of glyphosate increased with the duration of treatment.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because only one dose level for glyphosate and MON 52276 was considered, only 8 animals were used per dose and per sex and the method of analysis of glyphosate and AMPA in urine and its validation were not fully reported.

Reliability criteria for *in vivo* toxicology studies

Publication: Panzacchi *et al*., 2018	Criteria met? Y/N/?	Comments
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines	N	Only a part of the reproductive toxicology study was reported, one dose level of glyphosate or MON 52276 was considered and 8 females per dose group were used.
Study performed according to GLP	N	
Study completely described and conducted following scientifically acceptable standards	Y	For the part that was reported.
Test substance		
Test material (Glyphosate) is sufficiently documented and reported (i.e. purity, source, content, storage conditions)	Y	Glyphosate (purity of > 99,5 %), Pestanal™ analytical standard purchased from Sigma-Aldrich (Milan, Italy).
Only glyphosate acid or one of its salts is the tested substance	N	The representative formulated product, Roundup Bioflow (MON 52276, containing 360 g/L of

		glyphosate acid in the form of 480 g/L isopropylamine salt of glyphosate (41.5 %), water (42.5 %) and surfactant (16 %) was purchased from Consorzio Agrario dell'Emilia, Bologna, Italy.
AMPA is the tested substance	Y	Determined in urine of rats treated with glyphosate and MON 52276.
Study		
Test species clearly and completely described	Y	Male and female SD rats.
Test conditions clearly and completely described	Y	
Route and mode of administration described	Y	Oral via drinking water.
Dose levels reported	Y	1.75 mg glyphosate acid eq./kg bw/day administered as glyphosate and as MON 52276.
Number of animals used per dose level reported	Y	8 virgin female SD rats per dose group.
Method of analysis described for analysis test media	N	
Validation of the analytical method	N	
Analytical verifications of test media	N	
Method of analysis described for analysis of urine	N	No details on the conduct of the method of analysis and no complete validation data set.
Complete reporting of effects observed	Y	Limited to body weight,
Statistical methods described	Y	
Historical control data of the laboratory reported	N	
Dose-effect relationship reported	N	Not possible with one dose level of each test item.
Overall assessment		
Reliable without restrictions		
Reliable with restrictions	Y	
Reliability not assignable		
Not reliable		
This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because only one dose level for glyphosate and MON 52276 was considered, only 8 animals were used per dose and per sex and the method of analysis of glyphosate and AMPA in urine and its validation were not fully reported.		

1. Information on the study

Data point:	**CA 5.6.1/022**
Report author	Perego, M.C. *et al.*
Report year	2017
Report title	Evidence for direct effects of glyphosate on ovarian function: glyphosate influences steroidogenesis and proliferation of bovine granulosa but not theca cells *in vitro*
Document No	DOI 10.1002/jat.3417 E-ISSN: 1099-1263
Guidelines followed in study	None
Deviations from current test guideline	Not applicable
Previous evaluation	None
GLP/Officially recognised testing facilities	No
Acceptability/Reliability:	Yes/Reliable with restriction

2. Full summary of the study according to OECD format

The aim of this study was to determine the potential endocrine disruptor effects of glyphosate (GLY) on ovarian function evaluating cell proliferation, steroidogenesis and gene expression using bovine granulosa cells (GC) and theca cells as *in vitro* models. GC proliferation was impaired ($P<0.05$) after exposure to GLY at 0.5, 1.7 and 5 µg/mL. GC progesterone production was not affected ($P\geq0.05$) at all doses tested, while estradiol production was inhibited ($P< 0.05$) by GLY at 5 µg/mL. At the same concentration, GLY showed no effect ($P\geq 0.05$) on theca cell proliferation and steroidogenesis. At the concentrations of 0.01 and 0.3 µg/mL), GLY had no significant effect ($P\geq0.05$) on GC proliferation and steroidogenesis. These studies, for the first time, suggest that GLY may affect the reproductive system in cattle via direct action on ovarian function; however, further studies will be required to understand better the mechanism of action and to determine the *in vivo* reproductive effects of GLY.

Materials and methods

Cell culture

Ovaries from non-pregnant beef heifers were collected from a local slaughterhouse and were treated as previously described (Lagaly *et al*., 2008; Langhout *et al*., 1991; Spicer & Aad, 2007). Thecal cells (TC) were collected from large (8–22 mm) follicles as previously described (Lagaly *et al*., 2008; Spicer & Chamberlain, 1998; Stewart *et al*., 1995). Follicular fluid was collected and final cell preparations were prepared in serum-free medium (Dulbecco's modified Eagle medium and Ham's F12) as previously described (Lagaly *et al*., 2008; Schreiber & Spicer, 2012). Trypan blue exclusion method was performed to determine viable cells (Langhout *et al*., 1991; Spicer *et al*., 1993; Tiemann *et al*., 2003a,b). Cells were then plated (2.5×10^5 in 20–80 µL of medium) on 24-well Falcon multiwell plates (Becton Dickinson, Lincoln Park, NJ, USA) in 1 mL of basal medium composed of a mixture of 1:1 Dulbecco's modified Eagle medium and Ham's F-12 containing glutamine, gentamicin and sodium bicarbonate (Sigma-Aldrich Co., St. Louis, MO, USA) as previously described (Schreiber & Spicer, 2012). Plates were maintained in a humidified 95% air and 5% CO_2 environment at 38.5 °C changing medium every 24 h. Cells were also kept in the presence of 10% foetal calf serum (FCS; Equitech-Bio, Inc., Kerrville, TX, USA) for the first 48 h of culture to procure an optimal attachment. After 48 h, cells were washed twice with serum-free medium and the different treatments were applied in serum-free medium containing 500 ng/mL of testosterone (as an estradiol [E_2] precursor; from Steraloids, Wilton, NH, USA) for 48 h. Ovine follicle-stimulating hormone (FSH; NIDDK-oFSH-20, activity: 175 × NIH-FSH-S1 U mg^{-1}, from the National Hormone and Pituitary Program, Torrance, CA, USA) was added to all treatments, because insulin-like growth factor (IGF) 1 alone does not have an effect on steroid production (Ranzenigo *et al*., 2008; Spicer *et al*., 2002).

After aspiration of follicular fluid, large follicles were bisected and GC were separated from the TC via blunt dissection and the theca interna was enzymatically digested as previously described (Aad *et al*., 2006; Spicer & Chamberlain, 1998; Stewart *et al*., 1995). The non-digested tissue was eliminated by using sterile syringe filter holders with metal screens of 149 µm mesh (Gelman, Ann Arbor, MI, USA) and filtered TC were then centrifuged at 50 g for 5 min. As described for granulosa cells (GC), TC were washed with serum-free medium and resuspended in serum-free medium containing collagenase and DNase. TC (2.0×10^5 viable cells per well) were plated and cultured as described for GC. Culture medium was also supplemented with 30 ng/mL of ovine luteinizing hormone (LH; LH activity; 2.3 × NIH-LH-S1 U mg^{-1}; from the National Hormone and Pituitary Program) because progesterone (P_4) and androstenedione (A_4) production are not induced by IGF1 in the absence of LH (Spicer & Stewart, 1996; Stewart *et al*., 1995).

Assays
Medium collected from individual wells was frozen at -20 °C for subsequent steroid analyses. Radioimmunoassays (RIA) were performed to determine concentrations of P_4, E_2 and A_4 as previously described (Lagaly *et al*., 2008; Langhout *et al*., 1991; Spicer *et al*., 1993; Stewart *et al*., 1995). The intra- and inter-assay coefficients of variation were 7 % and 13 % for the P_4 RIA, and 8 % and 17 % for the E_2 RIA, respectively.

Determination of granulosa cell and theca cell numbers
The numbers of GC and TC, in the same wells from which medium was collected, were determined via a Coulter counter (model Z2; Beckman Coulter, Inc., Hialeah, FL, USA), and used to calculate steroid production on ng or pg per 10^5 cell basis. Cells were washed twice using 0.9 % saline solution (500 µL), exposed to 500 µL of trypsin (0.25 % wt/vol= 2.5 mg/mL) for 20 min at 37 °C and then scraped from each well and enumerated as previously described (Lagaly *et al*., 2008; Ranzenigo *et al*., 2008).

RNA extraction and quantitative reverse transcription–polymerase chain reaction
At the end of the treatment period, medium was either aspirated or collected from each well depending on the experiment and cells from two replicate wells were lysed in 0.5 mL of TRI reagent solution (Life Technologies, Inc., Grand Island, NY) as previously described (Lagaly *et al*., 2008; Spicer & Aad, 2007). RNA samples were solubilised in DEPC-treated water (Life Technologies, Inc., Grand Island, NY), quantitated by spectrophotometry at 260 nm using a NanoDrop ND-1000 spectrophotometer, and stored at -80 °C. Cholesterol side chain cleavage enzyme (*CYP11A1*) and aromatase (*CYP19A1*) primers and probes for quantitative reverse transcription–polymerase chain reaction were designed using Primer Express™ software (Foster City, CA, USA) as previously reported (Lagaly *et al*., 2008; Spicer & Aad, 2007). The bovine *CYP11A1* and *CYP19A1* primer and probe sequences and information are described by Lagaly *et al.* (2008). Relative quantification of target gene mRNAs were expressed using the comparative threshold cycle method as previously described (Lagaly *et al*., 2008; Spicer & Aad, 2007).

Experimental design
Experiment 1 was performed to evaluate the effects of glyphosate (GLY) on GC proliferation and steroidogenesis. Cells were cultured for 48 h in 10% FCS, washed twice with serum-free medium as described earlier, and cells treated for 48 h in serum-free medium containing testosterone (500 ng/mL), FSH (30 ng/mL) and IGF1 (30 ng/mL; recombinant human IGF1 from R&D Systems, Minneapolis, MN, USA) with or without various doses of GLY (i.e., 0, 0.5, 5 µg/mL; Sigma-Aldrich Co.). Only the 0 and 5 µg/mL doses of GLY were tested in the absence of IGF1 to determine any possible effect of GLY on FSH-stimulated steroidogenesis. After 48 h of treatment, cells were counted and medium was collected for E_2 and P_4 determinations. In a separate set of cells, the effect of 2–day treatment with 5 µg/mL GLY on GC viability was evaluated using the trypan blue exclusion method as previously described (Adashi *et al*., 1987; Spicer & Alpizar, 1994).

Experiment 2 was designed to evaluate the effects of higher doses of GLY on GC proliferation and steroidogenesis. Cells were cultured for 48 h in 10 % FCS, washed twice with serum-free medium as described earlier, and cells treated for 48 h in serum-free medium containing testosterone (500 ng/mL),

FSH (30 ng/mL) and IGF1 (30 ng/mL) with or without the various doses of GLY (i.e., 0, 0.01, 0.3 mg mL^{-1}). After 48 h of treatment, cells were counted and medium was collected for E2 and P_4 determinations.
Experiment 3 was designed to test the effect of GLY on *CYP11A1* and *CYP19A1* mRNA abundance in GC. Cells were cultured as previously described for experiment 1 except that no testosterone was included in the medium and treatments were only applied for 24 h: no additions, FSH (30 ng/mL) plus IGF1 (30 ng/mL), and FSH plus IGF1 plus GLY (5 µ/mL). After 24 h of treatment, cells were lysed for RNA extraction as described earlier. A combined treatment of FSH and IGF1 was selected to test the GLY effect because the inhibitory effect of GLY was seen with this treatment in experiment 1.

Experiment 4 was performed to study the effect of GLY on TC proliferation and steroidogenesis. Cells were cultured for 48 h in 10 % FCS, washed twice with serum-free medium as described earlier, and cells treated for 48 h in serum-free medium containing LH (30 ng/mL) and IGF1 (0 or 30 ng/mL) with or without GLY (*i.e.*, 0 and 5 µg/mL). After 48 h of treatment, cells were counted and medium was collected for P_4 and A_4 determinations.

Experiment 5 was designed to determine the effect of GLY on serum-stimulated GC proliferation. Cells were cultured for 4 days in 10 % FCS. During the last 2 days of culture, cells were treated as follows: control (no additions) or GLY (1.7 µg/mL). At the end of treatment, cells were counted.

Statistical analysis
Experimental data are presented as the least squares means ± SEM of measurements from replicated culture wells. Each experiment was performed three times with different pools of GC collected from 10 to 20 ovaries for each pool and each treatment replicated three times within each experiment. Treatment effects and interactions were assessed using the GLM procedure of the Statistical Analysis System for Windows (version 9.2; SAS Inst. Inc., Cary, NY, USA). Main effects were treatment, experimental replicate (i.e., pool of cells) and their interaction. Steroid production was expressed as ng or pg per 10^5 cells per 24 h, and cell numbers determined at the end of the experiment were used for this calculation. Mean differences in cell growth and steroid production between treatments were determined using the Fisher's protected least significant difference procedure (Ott, 1977) $P \leq 0.05$ was considered statistically significant.

Results

Experiment 1: Dose–response of glyphosate on granulosa cell proliferation and estradiol and progesterone production in the presence of follicle-stimulating hormone with or without insulin-like growth factor 1
GLY at 0.5 and 5 µg/mL was found to decrease significantly the GC proliferation in the presence of FSH plus IGF1 (Fig. 1). Regarding steroid production, GLY at all tested concentrations (0.5 and 5 µg/mL) had no effect on GC P4 production (Fig. 2A). GLY had no effect on GC E2 production in the presence of FSH whereas GLY at 5 µg/mL decreased ($P<0.05$) E2 production in the presence of FSH plus IGF1 (Fig. 2B). Cell viability was not significantly affected by 2–day treatment with 5.0 µg/mL GLY (91.6 vs. 88.6±5.0 % for control and GLY-treated GC, respectively).

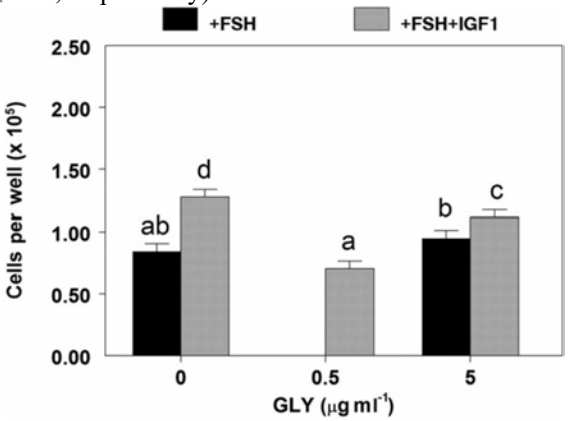

Figure 1. Effect of GLY on numbers of granulosa cells from bovine follicles (experiment 1). Cells were cultured for 48 h as described in Materials and methods, and then treated for an additional 48 h either with 30 ng/mL

FSH alone and GLY at 0 or 5 µg/ mL, or with 30ng/mL FSH and IGF1 (30 ng/mL) with GLY at 0, 0.5 or 5.0 µg/mL. All cells were treated concomitantly with 500 ng/mL of testosterone. Values are means ± SEM from three separate experiments (n = 9). Means without a common letter (a-d) differ (P<0.05). FSH, follicle-stimulating hormone; GLY, glyphosate; IGF, insulin-like growth factor.

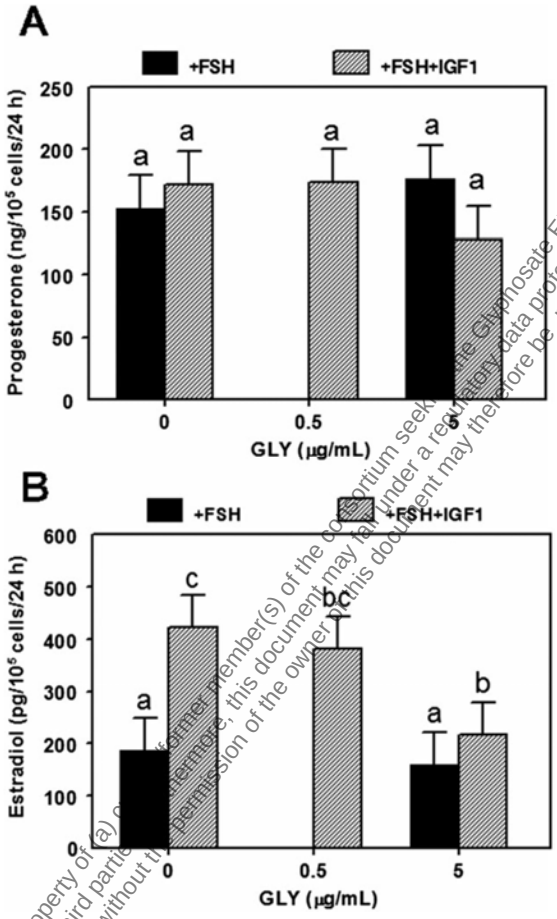

Figure 2. Effect of GLY on progesterone (A) and estradiol (B) production by granulosa cells from bovine follicles (experiment 1). Cells were cultured for 48 h as described in Materials and methods, and then treated for an additional 48 h either with 30 ng/mL FSH alone and GLY at 0 or 5 µg/mL, or with 30 ng/mL FSH and IGF1 (30 ng/mL) with GLY at 0, 0.5 or 5.0 µg/mL. All cells were treated concomitantly with 500 ng/mL testosterone. Values are means +/-SEM from three separate experiments (n = 9). Within a panel, means without a common letter (a–c) differ (P<0.05). FSH, follicle stimulating hormone; GLY, glyphosate; IGF, insulin-like growth factor.

Experiment 2: Dose–response of glyphosate on granulosa cell proliferation and estradiol and progesterone production in the presence of follicle-stimulating hormone plus insulin-like growth factor 1

GLY at all tested concentrations (0.01 and 0.3 mg/mL) had no significant effect either on GC proliferation or steroid production. Cell numbers averaged 1.25, 1.47 and 1.00 ± 0.2 (×105 cells per well) for 0, 0.01 and 0.3 mg/mL GLY, respectively. P4 production averaged 99, 154 and 91 ± 23 ng 10-5 cells per 24 h for 0, 0.01 and 0.3 mg/mL GLY, respectively. E2 production averaged 130, 157 and 187 ± 28 pg 10-5 cells per 24 h for 0, 0.01 and 0.3 mg/mL GLY, respectively.

Experiment 3: Effect of glyphosate treatment on CYP19A1 and CYP11A1 mRNA in granulosa cells

The combined IGF1 plus FSH treatment increased (P<0.05) CYP19A1 and CYP11A1 mRNA abundance

by threefold and twofold, respectively, above untreated control GC (Fig. 3A,B). GLY (5µg/mL) had no significant effect on CYP19A1 or CYP11A1 mRNA in GC co-treated with FSH and IGF1 (Fig. 3A,B).

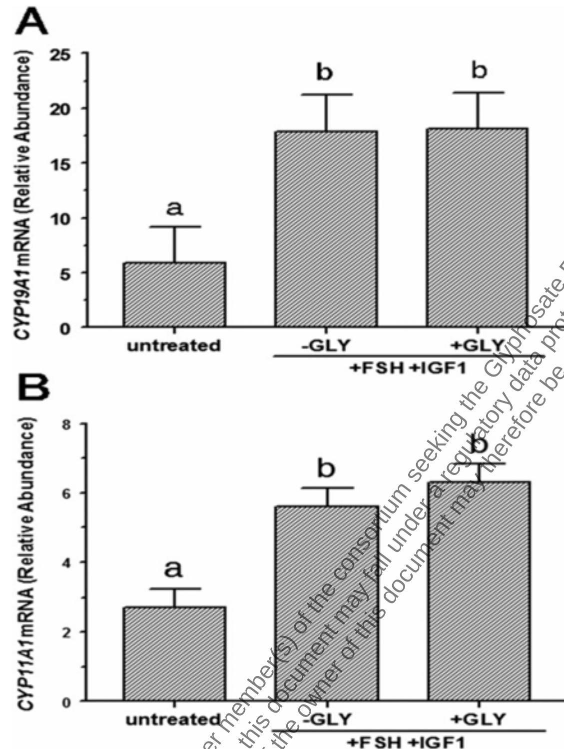

Figure 3. Effect of GLY on abundance of CYP19A1 (A) and CYP11A1 (B) mRNA in granulosa cells frombovine follicles (experiment 3). Cells were cultured for 48 h as described in Materials and methods, and then treated for an additional 24 h either with either no additions (controls), or with FSH (30 ng/mL) and IGF1 (30 ng/mL) with GLY at 0 or 5.0 µg/mL. Values are means ± SEM from three separate experiments (n = 6). Within a panel, means without a common letter (a–b) differ (P<0.05). FSH, follicle stimulating hormone; GLY, glyphosate; IGF, insulin-like growth factor.

Experiment 4: Dose–response of glyphosate on theca cell proliferation and androstenedione and progesterone production in the presence of luteinizing hormone with or without insulin-like growth factor 1

GLY at the tested concentration of 5 µg/mL had no significant effect on TC proliferation and P4 or A4 production in the presence of LH either with or without IGF1. IGF1 significantly increased cell numbers and steroid production. Cell numbers averaged 0.46, 0.53, 0.99 and 1.06 ± 0.05 for: LH alone; LH plus 5 µ/mL GLY; LH plus IGF1; and LH plus IGF1 plus 5 µ/mL GLY, respectively. P4 production averaged 40.5, 40.4, 70.3 and 78.3 ± 3.7 pg 10-5 cells per 24 h for: LH alone; LH plus 5 µg/mL GLY; LH plus IGF1 alone; and LH plus IGF1 plus 5 µg/mL GLY, respectively. A4 production averaged 1.45, 1.37, 2.75 and 2.47 ± 0.12 ng 10-5 cells per 24 h for: LH alone; LH plus 5 µg/mL GLY; LH plus IGF1 alone; and LH plus IGF1 plus 5 µg/mL GLY, respectively.

Experiment 5: Effect of glyphosate on serum-induced granulosa cell proliferation

Alone, GLY (1.7 µg/mL) increased (P<0.05) GC proliferation (Fig. 4). Cell numbers were increased by 11 % after 1 day and by 8 % after 2 days of GLY treatment (Fig. 4).

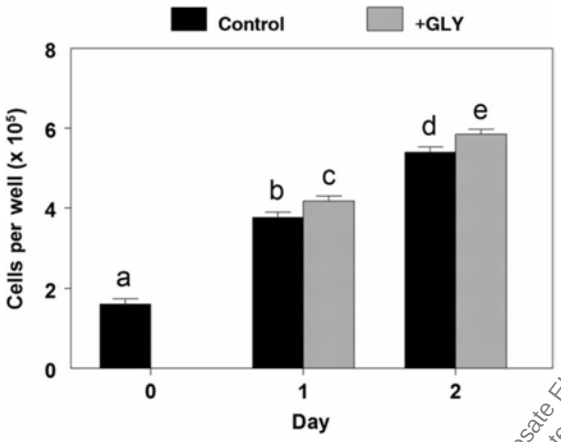

Figure 4. Effect of GLY on serum-induced proliferation of bovine granulosa cells (experiment 5). Cells were cultured for 48 h as described in Materials and methods, and then treated for an additional 0, 1 or 2 days with 10 % foetal calf serum and GLY at 0 or 1.7 µg/mL. Values are means ± SEM from three separate experiments (n = 9).Means without a common letter (a–e) differ (P<0.05). GLY, glyphosate.

Discussion

In the present study, both cell proliferation and the production of P4, A4 and E2, hormones that are connected to normal ovarian cyclicity and establishment and maintenance of pregnancy (Wood & Strauss, 2002), were evaluated to determine if GLY has effects on bovine GC and TC. GLY was tested at low doses, from 0.5 µ/mL, very far below agriculture use and authorised residues in food or feed (approximately 7000 and 800 times lower, respectively) (Gasnier et al., 2009). No effects were observed on GC P4 production in the presence of FSH either with or without IGF1, whereas GLY at 5 µg/mL had inhibitory effects on E2 production in the presence of FSH plus IGF1, showing a potential impairment on GC function that is essential for oocyte survival (Petro et al., 2012). Results of our study also showed that GLY at 5 µg/mL had an inhibitory effect on GC proliferation in the presence of FSH plus IGF1, and this inhibitory effect of 5 µg/mL GLY on cell numbers was not associated with a change in cell viability.

1.Assessment and conclusion

<u>Assessment and conclusion by applicant</u>:

In this *in vitro* study, glyphosate had minimal effects on granulosa cells (GC). In the presence of FSH only, glyphosate had no effect on GC cell viability or on progesterone or estradiol production. In the presence of FSH and IGF1, glyphosate reduced GC proliferation without a dose-response at 0.5 and 5 µg/mL but not at lower test concentrations (0.01 and 0.3 µg/mL) and did not affect progesterone production or CYP19A1 and CYP11A1 mRNA expression; estradiol production was reduced at 5 µg/mL only (not at lower test concentrations). Without FSH or IGF1, 1.7 µg/mL of glyphosate slightly increased GC proliferation in response to serum (≤11 %).

Glyphosate at 5 µg/mL had no effect on the theca cell (TC) proliferation or the production of progesterone or androstenedione.

Overall, with the exception of slight, non-dose-related alterations in GC proliferation under different test conditions, this study showed no effects of glyphosate on GC at physiologically relevant test concentrations. Glyphosate had no effect on TH.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate tested was not sufficiently characterised, no positive controls were used and the tests were conducted with only one or 2 test concentrations of glyphosate.

1. Full summary of the study according to OECD format

Many studies have been published already on reproductive toxicity of glyphosate-based formulations, but few investigated toxicity of glyphosate alone on the male reproductive system. In this study SD rats were gavaged with glyphosate at doses of 5, 50, 500 mg/kg to detect the toxicity of glyphosate on rat testis. Glyphosate significantly decreased the average daily feed intake at dose of 50 mg/kg, the weight of seminal vesicle gland, coagulating gland as well as the total sperm count at dose of 500 mg/kg. Immunohistochemistry of androgen receptor (AR) had no difference among all groups. Testosterone, estradiol, progesterone and oxidative stress parameters showed no differences for all doses. Taken together, it had been concluded that glyphosate alone has low toxicity on male rats reproductive system.

Materials and Methods

Chemicals - Isopropylamine salt of glyphosate (90 % w/w purity) was purchased from Shanghai Ryon Biological Technology Co. Ltd., China.

Animals - 32 sexually mature 56–day old Sprague-Dawley (SD) male rats were raised in an animal house and maintained in an air-conditioned room at approx. 21 °C with a 12 h/12 h light/dark cycle. A balanced mixture of pelleted food and water were available to the rats.

Experimental design and treatment – 32 rats were randomly divided into 4 groups, 3 groups were orally given glyphosate as an aqueous solution by gavage once a day. The control group was treated in the same way with deionised water. The doses administered were 5, 50, and 500 mg/kg bw. All rats were treated for 5 weeks continuously. After the last treatment the rats were sacrificed and testis, epididymis, prostate gland and seminal vesicle removed and weighed.

Epididymal sperm parameters – Epididymal sperm was used for the measurement of total sperm count. The epididymis was minced in PBS and filtered using a nylon mesh screen. The filtrate was treated with 10 mL PBS and the number of sperm was counted using a standard hemo-cytometric method.

Hormone measurement - Serum hormones were measured by radioimmunoassay using a ^{125}I-labeled ligand double-antibody RIA Kit for total testosterone, estradiol and progesterone. The minimum sensitivity of the method was 0.02 ng/mL for testosterone, less than 0.2 ng/mL for progesterone and less than 5 pg/mL for estradiol. The intra- and inter-assay coefficients of variation (CV) were less than 10 %.

Testicular, epididymal and seminal vesicle gland histology - Following fixation of the tissues, the samples were passed through a graded series of ethanol and xylene solutions and embedded in paraffin wax. Paraffin-embedded tissues were serially sectioned at 5 µm thickness. For each rat, two non-serial sections were stained with hematoxylin/eosin (HE).

Antioxidant status analysis - The levels of catalase (CAT, U/mg protein), superoxide dismutase (SOD, U/mg protein) and malondialdehyde (MDA, µmol/g protein) were determined by the absorbance of samples

in multiskan spectrum. SOD activity was determined by an SOD assay kit with absorbance measured at 560 nm. CAT activity was determined by the H_2O_2 consumption (µmol/g protein) with absorbance measured at 405 nm. Lipid peroxidation was determined by measurement of MDA by the TBA test with absorbance at 532 nm.

Immunohistochemistry - Sections of the testes were deparaffinised with xylene and rehydrated in graded ethanol before being washed with twice-distilled water. To increase epitope exposure, the sections were heated for 15 minutes in sodium citrate buffer (0.01 M, pH 6.0) in a microwave oven. The sections were then cooled and washed with 0.01 M PBS at pH 7.2 and then blocked with 10% bovine serum albumin (BSA) in TBST (20 mM Tris-buffered saline, 0.05 % Tween 20, pH 7.5) for 1 hour at room temperature. The sections were incubated overnight at 4°C with diluted (1:400) polyclonal antibodies against androgen receptor (N-20; rabbit anti-human AR). The secondary antibody was goat anti-rabbit IgG. The binding of the antibodies were visualised using a SABC Kit Elite and 0.05 % 3,3-diaminobenzidine tetrachloride in 0.01 M PBS at pH 7.2, containing 0.01 % H_2O_2 for 2 minutes. The sections were counter stained with hematoxylin and mounted with cover slips. The specificity of the antibody was examined using 1 % BSA rather than the primary antibody.

Data analysis - All results are means ± SEM. When multiple comparisons were performed, evaluation was done using one-way ANOVA followed by Tukey's multiple comparison test. Significant differences with controls were considered when $p<0.05$.

Results

Average daily weight gain and average daily feed intake – Daily exposure to glyphosate caused a statistically significant decrease in average daily feed intake at 50 mg/kg bw/day only. Although not statistically significant there was a dose-dependent decrease in daily weight gain.

Reproductive organ weights and sperm parameters - Seminal vesicle and coagulating gland absolute weight showed a statistically significant changes amongst treatment groups whereas no such change was observed in other reproductive organs. No significant differences were observed in relative reproductive organ weights. Total sperm count was statistically significantly decreased at 500 mg/kg bw. .

Concentrations of testosterone, estradiol and progesterone in serum - Although there was a trend towards decreased serum concentrations with dose for testosterone and progesterone no statistically significant changes were noted in the serum concentrations of testosterone, estradiol and progesterone.

SOD and CAT activity, *H_2O_2 and MDA levels in testes* - There were no statistically significant changes in SOD and CAT activity and H_2O_2 and MDA levels in testes.

Testicular, epididymal and seminal vesicle gland histology - No statistically significant changes were observed in the histopathology of the testis, epididymis and seminal vesicles.

Immunohistochemical localisation of androgen receptor in the testis - No statistically significant changes were observed in androgen receptor (AR) immunoreactivity localised in the nuclei of cells, including Sertoli cells, peritubular myoid cells and Leydig cells.

Discussion and conclusions

The present study provides information on the potential effects of glyphosate on the reproductive system of the male rat. Average daily weight gain showed no substantial decrease whereas average daily feed intake was significantly decreased at 50 mg/kg bw but not at 500 mg/kg bw. It is therefore suggested that the decrease of average daily feed intake is independent of glyphosate treatment. Although there are no statistically significant differences in average weight gain, the trend is a decrease. At 500 mg/kg bw the absolute weight of seminal vesicle gland and coagulating gland and total sperm count decreased substantially. There was no significant change in oxidative stress parameters after oral administration of glyphosate at doses up to 500 mg/kg bw. Testosterone, estradiol and progesterone serum levels, as well as

AR in testis presented no significant change at all dose levels tested when compared to controls.

2. Assessment and conclusion

Assessment and conclusion by applicant:
The potential toxicity of glyphosate to the male reproductive system of the rat has been investigated after oral treatment with glyphosate for 5 weeks at dose levels up to 500 mg/kg bw. The endpoints studied were body weight, food intake, daily weight gain, absolute and relative reproductive organ weight, serum hormone levels, oxidative stress parameters, testicular histopathology and expression of AR in testis. The effects found were a significant decrease in absolute (but not relative) weight of the seminal vesicle gland and coagulating gland and a decrease in sperm count at the highest dose tested.
This publication is considered relevant but reliable with restrictions because there are deviations from regulatory guidelines for reproductive toxicicity studies and the reproductive effects seen are not corroborated by the results from guideline studies at similar dose levels.

2. Full summary of the study according to OECD format

The aim of this study was to evaluate the effect of several structurally diverse endocrine disrupting compounds (EDCs) on steroidogenesis in a novel BLTK1 murine Leydig cell model. It was demonstrated that BLTK1 cells possess a fully functional steroidogenic pathway that produces low basal levels of testosterone (T) and express all the necessary steroidogenic enzymes including Star, Cyp11a1, Cyp17a1, Hsd3b1, Hsd17b3, and Srd5a1. Recombinant human chorionic gonadotropin (rhCG) and forskolin (FSK) elicited concentration- and time-dependent induction of 3',5'-cyclic adenosine monophosphate, progesterone (P), and T, as well as the differential expression of Star, Hsd3b6, Hsd17b3, and Srd5a1 messenger RNA levels. The results demonstrated that BLTK1 cells can be used to screen substances that alter intracellular cAMP, steroidogenic gene expression, and sex steroid levels. When tested in this system glyphosate was not found to induce testosterone production or alter rhCG induction of testosterone.

Materials and Methods

Chemicals - Purity and origin of the glyphosate sample tested was not reported.

Cell culture and treatment - Mouse Leydig BLTK1 (BLT-1 cells, clone K1) cells were isolated from a testicular tumor that developed in a transgenic mouse expressing the mouse inhibin α promoter/simian virus 40 T-antigen fusion gene. Cells were maintained in phenol red–free DMEM/F-12 media with 10% foetal bovine serum, 100 U/mL penicillin and 100 µg/mL streptomycin and incubated in 5 % CO_2 at 37 °C). For the evaluation of steroidogenic enzyme and receptor expression, cells were grown to 80% confluency and harvested without any treatment. For the determination of 3',5'-cyclic adenosine monophosphate (cAMP), progesterone (P), testosterone (T), and estradiol (E2), cells were grown to 80% confluency, transferred into

24-well tissue culture plates and incubated overnight. Cells were treated with DMSO, or with 0.1, 0.3, 1, 3, 10, 30, or 100 ng/mL recombinant human chorionic gonadotropin (rhCG) or with 0.1, 0.3, 1, 3, 10, 30, or 100 µM Forskolin (FSK) and media were collected at indicated times. Time course studies were conducted with DMSO, 3 ng/mL rhCG or 10 µM FSK, and media were collected after 1, 2, 4, 8, 12, 24, or 48 hours of incubation. Gene expression studies used the same study design, concentrations and time points with cells seeded into T-25 flasks.

MTT assay - BLTK1 cells placed in 96-well plates were treated with 1, 3, 10, 30, 100, 300, or 600 ng/mL rhCG, 1, 3, 10, 30, 100, 300, or 600 µM FSK or 1, 3, 10, 30, 100, 300, or 600 µM of test compound in triplicate. Media were aspirated after 24 hours and replaced with 50 µL of fresh MTT reagent (5 mg/mL thiazolyl blue tetrazolium bromide in PBS). Following 3 hours of incubation, MTT reagent was removed and replaced with 150 µL DMSO. Cells were incubated for 2 hours followed by absorbance measurements at 595 and 650 nm using an Emax precision microplate reader. Results are reported as percentage of control calculated from the relative absorbance of treated versus DMSO controls where 100 % indicates no cytotoxicity.

RNA isolation and gene expression - Total RNA was extracted from cell pellets using RNeasy Mini Kits with an additional RNase-free DNase digestion. RNA was quantified at 260 nm and purity assessed using the A260/A280 ratio, as well as by denaturing gel electrophoresis. First-strand complementary DNA (cDNA) was synthesized from RNA (1 µg) using SuperScript II reverse transcriptase and anchored oligo-dT primer. For real-time PCR (RT-PCR) evaluation of steroidogenic enzyme and receptor expression, cDNA was used as a template for PCR amplification with gene-specific primers. Quantitative RT-PCR (QRT-PCR) was used to quantify concentration- and time-dependent expression of specific genes. Reactions in 96-well plates consisted of 30 µL, including 1 µL of cDNA template, 0.1 µM forward and reverse gene-specific primers using an Applied Biosystems PRISM 7500 Sequence Detection System. Dissociation curve analysis assured single product amplification. To control for differences in RNA loading, quality and cDNA synthesis, samples were standardised to the geometric mean of three housekeeping genes: *ActB*, *Gapdh*, and *Hprt*. Results were quantified using a standard curve generated on the same 96-well plate and amplified by using purified cDNA product as template specific for each gene (serial 10-fold dilutions from 10^8 to 10^1 copies). The slope of the standard curve was used to assess amplification efficiency with all amplification efficiencies > 90 %. Fold changes were calculated relative to time-matched vehicle. Relative expression was scaled such that time-matched vehicle control expression equaled one for graphing purposes.

Dose-response modeling and statistical analyses - The ToxResponse modeler uses particle swarm optimisation to identify the best fit across five model classes: sigmoidal, exponential, linear, quadratic, and Gaussian. The best fitting model was then used to calculate half maximal effective concentration (EC_{50}) values. All statistical analyses were carried out using SAS v9.1 by ANOVA, with Dunnett's or Tukey's *post hoc* tests for concentration-response and time course data, respectively. Differences between treatment groups were considered significant when $p<0.05$ relative to time-matched DMSO control.

Results

Steroidogenic Enzyme Expression in BLTK1 Cells - Steroidogenic enzyme messenger RNA (mRNA) and protein were detected in BLTK1 cells by RT-PCR and/or Western blotting, confirming the expression of all required steroidogenic enzymes. In addition, mRNA for several potential regulatory factors including LHCGR, estrogen receptor (ER), androgen receptor (AR), and steroidogenic factor 1 (SF-1), peroxisome proliferator-activated receptors (PPARa and PPARc), the pregnane X receptor (PXR), and the aryl hydrocarbon receptor (AhR) were also detected. However, mRNA for progesterone receptor, glucocorticoid receptor, or the liver receptor homolog 1 was not detected in BLTK1 cells despite verification of RT-PCR primer specificity and functionality in mouse Hepa1c1c7 cells.

Induction of Steroidogenesis by FSK and rhCG - Temporal profiles of intracellular cAMP as well as P and T levels in media were evaluated in response to 3 ng/mL rhCG or 10 µM FSK by enzyme immunoassay (EIA). Intracellular cAMP was induced by FSK after 30 minutes (~120 pmol/mL, ~10-fold) and after 1 hour in response to rhCG (635 pmol/mL, 60-fold). However, levels quickly diminished such that no intracellular

cAMP was detected by 8 hours. Maximum P levels (200 ng/mL, 8-fold) were observed after 2 hours in response to rhCG and FSK, followed by a steady decline due to metabolism to androgens and estrogens. In contrast, T levels gradually increased reaching a maximum of ~200 pg/mL (7-fold) after 48 hours, with significant increases as early as 1 hour post treatment. Concentration-dependent induction of intracellular cAMP and secreted P and T was evaluated after 4 hours when cAMP could still be detected. 17β-Estradiol (E2) was evaluated after 48 hours as it was not consistently detected after 4 hours. cAMP, P, and T were induced 25-, 10-, and 4-fold, respectively, after 4 hours, whereas E2 was induced ~4-fold by 48 hours. The EC_{50} for cAMP induction was greater than 24 ng/mL for rhCG and greater than 29 µM for FSK. Meanwhile, EC_{50} values of 1 ng/mL rhCG and 9 µM FSK were conserved for both P and T induction, whereas E2 EC_{50} values were 10 ng/mL for rhCG and 9 µM for FSK. Intracellular cAMP levels are not only regulated by synthesis but also by degradation, which is regulated by cyclic nucleotide phosphodiesterase enzymes. The phosphodiesterase inhibitor IBMX maximizes cAMP levels in order to further induce steroidogenesis. However, IBMX co-treatment with rhCG or FSK did not increase T levels further, albeit rhCG and FSK potencies were greater with and without IBMX by FSK: 0.1 µM vs. 9.4 µM vs. 0.9 ng/mL, respectively. When tested in this system glyphosate at 300 µM did not induce T production nor alter rhCG induction of T.

Conclusion
Current test protocols and models are inadequate to screen the universe of chemicals, metabolites, and mixtures that may alter steroidogenesis. BLTK1 cells are a novel complementary rhCG-inducible Leydig-based model that can be used to assess effects on steroidogenic gene expression, intracellular cAMP, and P, T, and E2 levels in media. Their consistent response characteristics and inducibility over 30 passages also make this cell line attractive for high-throughput screening. Comprehensive characterisation of effects on intermediate steroid biosynthesis, including pregnenolone, 17-hydroxyprogesterone, DHEA, androstenedione, estrone, and DHT, as well as the differential expression of steroidogenic enzymes will also facilitate the elucidation of modes of action relevant to adverse outcome pathways in humans and other relevant species. When tested in this system glyphosate at 300 µM did not induce testosterone production or alter rhCG induction of testosterone.

1. Assessment and conclusion

Assessment and conclusion by applicant:

In this study, recombinant human chorionic gonadotropin (rhCG) and forskolin (FSK) were used as positive controls for the induction of steroidogenesis, as measured by increases in progesterone, testosterone and 17β-estradiol levels in culture media. Murine BLTK1 Leydig cells were investigated as a novel model for evaluating the effects of chemicals on steroidogenesis. The results demonstrated that BLTK1 cells can be used to screen substances that alter intracellular cAMP, steroidogenic gene expression, and sex steroid levels. When tested in this system glyphosate was not found to induce testosterone production or alter rhCG induction of testosterone.

This publication is considered relevant for glyphosate risk assessment but reliable with restrictions because the test substance was not characterised and the results of only one concentration level were reported.

CA 5.6.2 Developmental toxicity studies

Developmental toxicity of glyphosate was tested in a variety of studies in rats and rabbits.

Rat studies

Seven toxicity studies in rats are available for the assessment of developmental toxicity of glyphosate, 5 amongst them are considered as valid and conclusive for hazard assessment. Those studies have been taken into account for the previous and current evaluation of developmental toxicity of glyphosate in the rat. Two studies are considered invalid for hazard assessment (please refer to study summaries CA 5.6.2/006 and CA5.6.2/007) but are included for the sake of completeness. No new data on developmental toxicity obtained in rats, including publically available sources, are available for the current dossier. A brief summary of the available studies conducted in the rat is provided below.

Table 5.6.2-1: Summary of developmental toxicity in rats

Annex Point	Study	Study type	Substance(s)	Reference list- related category§	Result	
					NO(A)EL [mg/kg bw/day] {previous AIR value, where different}	LOAEL Targets / Main effects {previous AIR noted effects}

§ The category describes the acceptability/reliability of the study within the AIR 5 submission. This category does not describe hazard classification.

In the developmental study performed by [redacted] (1996) (CA 5.6.2/001), no evidence of maternal and developmental toxicity due to glyphosate acid exposure during gestation was observed. Further, no teratogenic effects were apparent. Thus, the highest tested dose level of 1000 mg glyphosate acid/kg bw/day was the No-Observed-Effect-Level (NOEL) for both maternal and developmental effects.

In the second study ([redacted] (1995) (CA 5.6.2/002)), a dose of 1000 mg/kg bw/day did not lead to treatment-related toxicity except slight disturbances of the gastrointestinal tract in maternal animals indicated by slightly loose stool and decreased food consumption at the early dosing period from gestational day 6 - 9. No treatment-related changes were observed in regard to body weights and body weight gains. Gravid uterine weights, numbers of corpora lutea, implants and live foetuses, percent incidences of resorptions and foetal deaths, foetal sex ratio, foetal body weights and placenta weights were comparable among the test groups. Further, no treatment related effects including malformations or variations were noted in foetuses. Thus, the No-Observable-Adverse-Effect-Level (NOAEL) was set at 300 mg/kg bw/day for maternal rats, and 1000 mg/kg bw/day for developmental toxicity.

Materntal toxicity characterised by gastrointestinal disturbances (loose stool/diarrhoea) at 1000 mg/kg bw/day was confirmed by [redacted] (1991) (CA 5.6.2/003). Besides gastrointestinal disturbances, reduced body weight gain and/or noisy respiration were observed indicating for maternal toxicity at this dose level (CA 5.6.2/003). Further, mortality, post dose salivation and lower food consumption were observed in dams at the top dose of 3500 mg/kg bw/day. No abortions or total resorptions were detected. Implantation rate, post-implantation loss, litter size and sex ratio were similar in all groups. In foetuses, a reduction in mean foetal weight was observed at the highest dose of 3500 mg/kg bw/day. A higher incidence of rib distortion (wavy ribs) was evident in the high-dose group. In addition, reduced ossification was seen slightly more frequently at this dose level and also at 1000 mg/kg bw/day. As result, the percentage of foetuses showing skeletal anomalies (variations) was significantly increased at the mid- and high-dose levels. However, the percentage for the mid-dose level only slightly exceeded the historical background range (21.9 - 27.2 %) whereas the respective control value was atypically low in this study. The toxicological relevance of findings at 3500 mg/kg bw/day is uncertain because of the clear increase in mortality in dams at this dose level suggesting an excess of the maximum tolerated dose. Effects observed

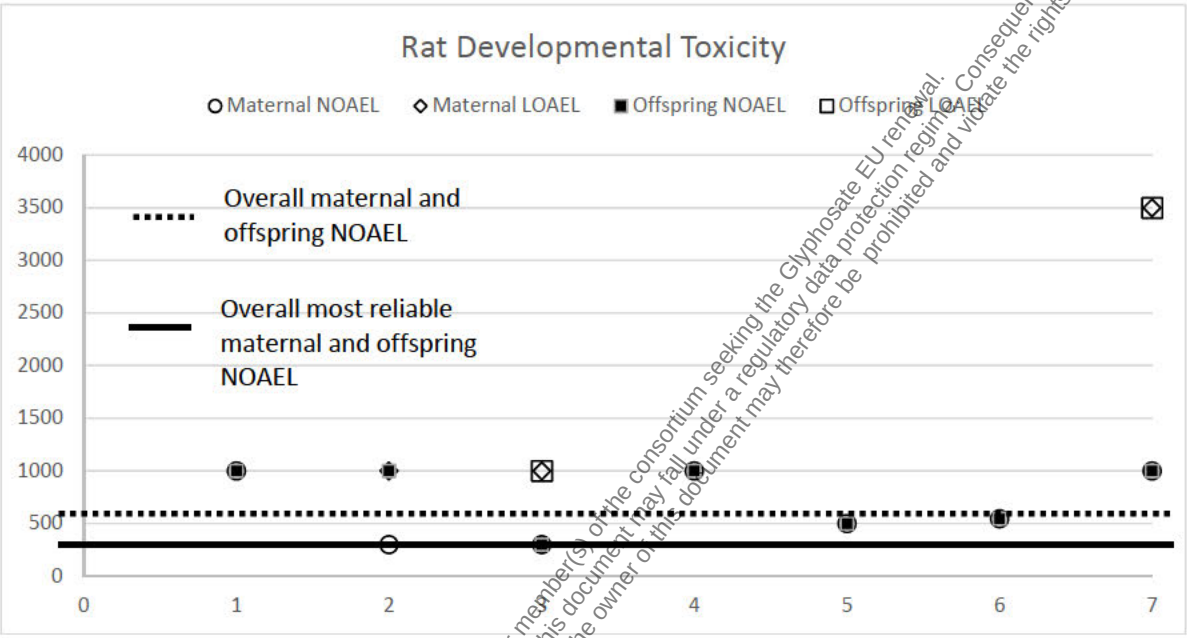
in foetuses at these high doses are attributed to secondary, non-specific consequences of maternal toxicity and not to specific developmental toxicity. No teratogenicity was observed. Treatment with glyphosate at 300 mg/kg bw/day was without adverse effect on maternal or embryofoetal parameters.

A further teratogenicity study conducted as a limit test at 1000 mg/kg bw/day is available ([redacted] (1991) (CA 5.6.2/004 and CA 5.6.2/005)). No evidence of maternal toxicity was observed. Reproduction indices and litter data were comparable to the controls and did not indicate treatement related toxicity. The incidence of foetal malformations was not increased in the treated group compared to the control. There was limited evidence of a higher incidence of delayed ossification (caudal vertebral arch, forelimb proximal and hindlimb distal phalanges) in the group receiving glyphosate. On the other hand, delayed ossification of other parts of the skeleton, in particular the skull, was more frequently seen in the control group. Thus, there was no clear and consistent impact of test compound administration on the process of ossification. The NOAEL for maternal and embryofoetal toxicity was defined as 1000 mg/kg bw/day.

Similar to [redacted], [redacted] [redacted] (1980) (CA 5.6.2/008) exposed dams to doses of glyphosate up to 3500 mg/kg bw/day. Biologically meaningful differences in appearance and behavior were noted at 3500 mg/kg bw/day when compared to the control group and included breathing rattles, reduced activity and an increase in soft stool and diarrhoea. Six animals in this dose group died of unknown reasons by gestation day 17. Reduced mean maternal body weight gain was noted over the treatment period in the 3500 mg/kg bw/day group. Further, an increase in early resorptions, a slight increase in post-implantation loss and decreases in mean foetal body weight and mean number of viable foetuses was observed at 3500 mg/kg bw/day. An increase in the number of foetuses with reduced ossification of the sternebrae was also noted in this group. No signs of maternal or developmental toxicity were noted at 300 or 1000 mg/kg bw/day. Glyphosate did not produce a teratogenic response when administered to rats up to and including 3500 mg/kg bw/day. The maternal and developmental NOAEL are considered to be 1000 mg/kg bw/day.

The available studies on developmental toxicity consistently revealed that *in utero* exposure to glyphosate did not result in teratogenicity in rats. If observed, test substance-related effects, including maternal toxicity and developmental effects occur at 1000 mg/kg bw/day. Based on the available data an "overall" NOAEL of 544 mg/kg bw/day is considered appropriate for both maternal and developmental toxicity in rats. However, given the unreliability of studies by [redacted] (1986) (CA 5.6.2/006); NOAEL 500 mg/kg bw/day) and [redacted] (1981) (CA 5.6.2/007; NOAEL 544 mg/kg bw/day), the most reliable overall NOAEL for both maternal and developmental toxicity in rats is 300 mg/kg bw/day.

Figure 5.6.2-01. Rat developmental toxicity studies, maternal and developmental NOAEL and LOAEL values, showing overall maternal and developmental NOAEL of 544 mg/kg bw/day [1. [redacted] (1996) (CA 5.6.2/001); 2. [redacted], (1995) (CA 5.6.2/002); 3. [redacted] (1991) (CA 5.6.2/003); 4. [redacted] (1991) (CA 5.6.2/004 - 005); 5. [redacted] (1986) (CA 5.6.2/006); 6. [redacted] (1981) (CA 5.6.2/007); 7. [redacted] (1980) (CA 5.6.2/008)]



1. Information on the study

Data point:	**CA 5.6.2/001**
Report author	[redacted]
Report year	2002 (study report 1996, amendment 2002)
Report title	Glyphosate Acid: Developmental Toxicity Study in the Rat (Including Amendment 001 to Glyphosate Acid: Developmental Toxicity Study in the Rat)
Report No	[redacted]/P/4819
Document No	M-301383-01-1
Guidelines followed in study	OECD 414 (2001), OPPTS 870.3700 (1998), 2004/73/EC B.31 (2004)
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: Weight and histopathological changes of the thyroid glands of the dams, anogenital distance (AGD) in foetuses, indication of incomplete testicular descent/cryptorchidism in male foetuses. Blood samples from dams to assess thyroid hormones (T4, T3 and TSH) were not collected. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)

GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

In a developmental study, groups of time-mated female rats of the Alpk:APfSD (Wistar-derived) strain were dosed by gavage with 0, 250, 500 or 1000 mg glyphosate acid/kg/day using deionised water as a vehicle. The day of mating was designated day 1 of gestation. The rats were dosed on days 7-16 (inclusive) of gestation which thus included the period of major organogenesis. On day 22 of gestation the rats were killed and their uteri examined for live foetuses and intra-uterine deaths. The foetuses were weighed, examined for external and visceral abnormalities, sexed, eviscerated and stained for skeletal examination.

There was no evidence of maternal toxicity attributable to glyphosate acid as assessed by the clinical condition of the animals during the study, their body weight gain and food consumption and the type and incidence of macroscopic findings *post mortem*.

There was no evidence of developmental toxicity attributable to glyphosate acid as assessed by the number, growth and survival of the foetuses. Observation of the external appearance of the foetuses, examination of the viscera and assessment of the skeletons revealed no treatment-related findings.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:	Glyphosate acid
Description:	Technical, white solid
Lot/Batch number:	P24
Purity:	95.6% w/w a.i
CAS#:	Not reported
Stability of test compound:	Confirmed
Vehicle:	Deionised water
Test Animals:	
Species	Rat
Strain	Alpk:APfSD Wistar-derived
Age/weight on arrival	Approximately 11 weeks / 210 - 303 g
Source	[redacted]
Housing	Individually
Acclimatisation period	Not applicable
Diet	CT1 diet (Special Diet Services, Witham, Essex, UK) *ad libitum*
Water	Mains water *ad libitum*
Environmental conditions	Temperature: 21 ± 2 °C Humidity: 40 – 70 % Air changes: 25 - 30 changes / hour Photoperiod: 12 hours light / 12 hours dark

B. STUDY DESIGN

Dates of Experimental work: 1995-05-17 to 1996-03-26

In-life dates: Start: Not reported End: Not reported (QA audits conducted between May 1995 and March 1996)

Mating procedure: Virgin female rats were paired overnight (at the Breeding Unit) with males of the same strain. On the following morning, vaginal smears from these females were examined for the presence of sperm. The day when spermatozoa were detected was designated day 1 of gestation and, on this same day, successfully mated females were delivered to the experimental unit at [redacted].

Animal assignment: A total of 96 mated females was supplied over a two–week period. Twelve female rats were supplied on each of eight days. The study was divided into twenty-four replicates (randomised blocks) with each replicate containing one rat from each group. Animals were randomly assigned to test groups as shown in the following table.

Table 5.6.2-2: Glyphosate acid: Developmental toxicity study in the rat ([redacted], 1996): Animal numbers and treatment groups

Glyphosate acid (mg/kg bw/day)				
	0 (control)	**250**	**500**	**1000**
Animal Numbers	1 - 24	25 - 48	49 - 72	73 - 96

Dose selection rationale: The dose levels selected for this study were based on a dose range finding study in the pregnant rat. The highest dose level of 1000 mg/kg/day is the limit dose for this type of study.

Dose preparation and analyses: Glyphosate acid was administered in deionised water and the concentration was adjusted to give a constant volume of 1 mL/100 g body weight for each dose level. An appropriate amount of deionised water was added to a weighed amount of test substance (adjusted for purity) to provide each preparation. One preparation per concentration (i.e. 25, 50 and 100 mg/mL) was made. Each preparation was thoroughly mixed before being subdivided into aliquots. The control substance was also dispensed into aliquots. The aliquots were stored at room temperature and fresh aliquots were used for each day of the study.

A sample of each preparation was analysed prior to the start of dosing to verify the achieved concentrations of glyphosate acid in deionised water. Samples of the lowest concentration of dosing formulation was analysed to confirm the homogeneity of glyphosate acid in deionised water. The homogeneity of the 100 mg/mL formulation was not determined as part of this study and the data have been obtained from a preliminary study ([redacted] *1995*) for which the method of preparation of the dosing formulations was the same. The chemical stability of glyphosate acid in deionised water was determined by re-analysis of the lowest and highest concentrations of dosing formulation after an interval of 26 days.

Concentration analysis results: The achieved concentrations of glyphosate acid in deionised water were within 5% of nominal concentrations.
Homogeneity results: The homogeneity of glyphosate acid in deionised water at concentrations of 25 mg/mL and 100 mg/mL was within 5 % of the overall mean.
Stability results: The stability of the 25 mg/mL and the 100 mg/mL formulations was satisfactory over a period of 26 days which exceeded the period of use in this study.

Dose administration: All animals were dosed once daily from days 7 - 16 (inclusive) of gestation with 1 mL of dosing formulation per 100 g body weight using a disposable syringe and a plastic nelaton catheter. The volume given to each animal was adjusted daily according to body weight. Control animals received the appropriate volume of deionised water. Dosing was performed in group order with all animals receiving the same dose level being dosed sequentially.

Maternal Observations:
Clinical observations: All animals were observed on arrival to ensure that they were physically normal externally and were subsequently observed at least twice each day. Any changes in behaviour or clinical condition were recorded daily during the study.

Body weight: The body weight of each animal was recorded on arrival and on days 4, 7 - 16 (inclusive) and on days 19 and 22 of gestation.

Food consumption: The amount of food consumed by each animal over three day periods was measured by giving a weighed quantity of food contained in a glass jar on days 1, 4, 7, 10, 13, 16 and 19 and calculating the amount consumed from the residue on days 4, 7, 10, 13, 16, 19 and 22, respectively.

Necropsy: One rat requiring euthanasia was killed by over-exposure to halothane Ph. Eur. vapour and given a macroscopic examination *post mortem*.

On day 22 of gestation the animals were killed by over-exposure to halothane-Ph. Eur. vapour and a macroscopic examination *post mortem* was performed. The uterus from any animal without clear evidence of implantation was removed and stained with ammonium polysulphide to determine whether or not implantation had occurred.

For pregnant animals the intact gravid uterus (minus ovaries and trimmed free of connective tissue) was removed and weighed. The ovaries and uterus were then examined and the following data recorded:

Number of *corpora lutea* in each ovary
Number and position of implantations subdivided into:
- a) live foetuses
- b) early intra-uterine deaths (decidual or placental tissue only)
- c) late intra-uterine deaths (embryonic/foetal tissue plus placental tissue)

Individual foetal weights

The implantations were assigned letters of the alphabet to identify their position *in utero* starting at the ovarian end of the left horn and ending at the ovarian end of the right horn. In addition, each foetus was weighed and individually identified within the litter by means of a cardboard tag. After weighing the foetuses were killed with an intracardiac injection of approximately 0.1 mL of 200 mg/mL pentobarbitone sodium solution.

Percentage pre-implantation loss and percentage post-implantation loss were calculated.

$$\% \text{ pre-implantation loss} = \frac{\text{number of } \textit{corpora lutea} - \text{number of implantations}}{\text{number of } \textit{corpora lutea}} \times 100$$

$$\% \text{ post-implantation loss} = \frac{\text{number of implantations} - \text{number of live foetuses}}{\text{number of implantations}} \times 100$$

Foetal observations: An external examination of each foetus was made together with an examination of the oral cavity. All foetuses were then examined internally for visceral abnormalities, sexed, eviscerated and fixed in 70 % industrial methylated spirits. After approximately 24 hours the head of each foetus was

cut along the fronto-parietal suture line and the brain was examined for macroscopic abnormalities. The carcasses were then returned to 70% industrial methylated spirits for subsequent processing and staining with Alizarin Red S. The stained foetal skeletons were examined for abnormalities and the degree of ossification was assessed. The individual bones of the *manus* and *pes* were assessed and the result converted to a six point scale.

The observations were classified as major (permanent structural or functional deviations considered likely to be incompatible with survival or rarely seen) or minor defects or variants (small, generally transient deviations considered compatible with survival). The difference between the minor defect and variant classification is the frequency of occurrence in the control population of rats of this strain.

Statistical analyses: Data relating to animals which were non-pregnant, totally resorbed their litters or died intercurrently were excluded from the statistical analysis.

Maternal body weight during the dosing and post-dosing periods was considered by analysis of covariance on initial (day 7) body weight.

Maternal food consumption during the dosing and post-dosing periods, the numbers of implantations and live foetuses per female, gravid uterus weight, litter weight, mean foetal weights per litter and mean *manus* and *pes* scores per litter were considered by analysis of variance.

Maternal-performance data (excluding the animal with undetermined pregnancy status), the proportion of foetuses with each individual *manus* and *pes* score, the proportion of foetuses with each defect and the proportion of litters with each defect were considered by Fisher's Exact Test.

Pre-implantation loss, post-implantation loss, early intra-uterine deaths, late intra-uterine deaths, male foetuses, major external/visceral defects, minor external/visceral defects, external/visceral variants, major skeletal defects, minor skeletal defects and skeletal variants were analysed as follows:

- → Percentages were analysed by analysis of variance following the double arcsine transformation of *Freeman and Tukey (1950)*
- → the proportion of foetuses affected and with the exception of male foetuses the proportion of litters affected were considered by Fisher's Exact Test.

All analyses were carried out in *SAS (1989)*. For Fisher's Exact Test the proportion in each treated group was compared to the control group proportion. Analyses of variance and covariance allowed for the replicate structure of the study design. Least-squares means for each group were calculated using the LSMEAN option in SAS PROC GLM. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squares mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a Student's t-test, based on the error mean square in the analysis.

All statistical tests were two-sided.

II. RESULTS AND DISCUSSION

A. MORTALITY

One control animal was killed on day 7 as a result of being misdosed. There were no other mortalities.

B. CLINICAL OBSERVATIONS

Excess watery fluid in the thoracic cavity and dark red areas on the surface of the lung lobes were observed

at examination *post mortem* of the one control dam that was euthanised. The pregnancy status of the animal was not determined. There were no changes in the clinical condition of the other dams given glyphosate acid which were considered to be treatment-related.

C. BODY WEIGHT

There was no effect of glyphosate acid on maternal body weight.

Table 5.6.1-88: Glyphosate acid: Developmental toxicity study in the rat ([redacted], 1996): Intergroup comparison of maternal body weight (g) (selected timepoints, adjusted means for days 8 and 22)

	Glyphosate acid (mg/kg bw/day)			
Day	**0 (control)**	**250**	**500**	**1000**
1	255.6 ± 12.4 N=22	255.5 ± 16.4 N=24	253.5 ± 17.2 N=23	252.8 ± 24.0 N=23
8	288.2	288.1	288.0	287.5
22	406.4	410.1	411.1	408.6

D. FOOD CONSUMPTION

There was no adverse effect of glyphosate acid on maternal food consumption. The amount of food consumed by the animals given 1000 mg glyphosate acid/kg bw/day was marginally lower during the dosing period but differences from the controls were not statistically significant.

Table 5.6.1-89: Glyphosate acid: Developmental toxicity study in the rat ([redacted], 1996): Intergroup comparison of food consumption (g/day) (selected timepoints)

	Glyphosate acid (mg/kg bw/day)			
Day	**0 (control)**	**250**	**500**	**1000**
1-4	23.9 ±3.8	24.6±2.3	24.6±2.4	23.2±2.4
13-16	33.2±5.3	33.4±3.2	33.7±2.7	31.9±3.4
19-26	29.5±4.1	31.6±3.7*	30.5±3.1	30.5±3.6

* Statistically significant difference from control group mean, $p<0.05$ (Student's t-test, 2-sided)

E. NECROPSY

There were no macroscopic findings in the dams which were considered to be related to the administration of glyphosate acid.

Table 5.6.10: Glyphosate acid: Developmental toxicity study in the rat ([redacted], 1996): Intergroup comparison of macroscopic findings *post mortem*

* Statistically significant difference from control group mean, $p<0.05$ (Student's t-test, 2-sided)
** Statistically significant difference from control group mean, $p<0.01$ (Student's t-test, 2-sided)

Findings during external, visceral and skeletal examination:
Major defects: The incidence of foetuses with major defects was 1/284, 1/297, 1/301 and 2/296 in the control and 250, 500 and 1000 mg glyphosate acid/kg bw/day groups, respectively. Neither the type nor incidence of major defects provided evidence for an adverse effect of glyphosate acid. The defects were dissimilar in type and of single incidence.

Minor defect: The proportion of foetuses with minor external/visceral defects and the proportion of foetuses with minor skeletal defects were similar for all groups. Consideration of the specific defects provided no evidence for an adverse effect of glyphosate acid.

Variants: The proportion of foetuses with external/visceral variants and the proportion of foetuses with skeletal variants were lower in the glyphosate acid treated groups than in the control group. Consideration of the specific defects provided no evidence for an adverse effect of glyphosate acid.

III. CONCLUSIONS

There was no evidence of maternal or developmental toxicity attributable to glyphosate acid at any dose level. The dose level of 1000 mg glyphosate acid/kg bw/day was the NOEL in this study for both maternal and developmental effects.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study performed according to OECD 414 (2001) in rats, the NOEL for maternal and developmental effects was 1000 mg/kg bw/day based on no evidence of maternal or developmental toxicity attributable to glyphosate acid at any dose level.

Assessment and conclusion by RMS:

3. Information on the study

Data point:	**CA 5.6.2/002**
Report author	[redacted]
Report year	1995
Report title	HR-001: Teratogenicity Study in Rats
Report No	[redacted] 94-0152
Document No	M-301383-01-1
Guidelines followed in study	Japan MAFF Guidelines 59 NohSan No.4200, 1985 U.S. EPA FIFRA Guidelines Subdivision F, 83-3, 1984 OECD Guideline 414, 1981
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: Weight and histopathological changes of the thyroid glands of the dams, anogenital distance (AGD) in foetuses, indication of incomplete testicular descent/cryptorchidism in male foetuses. Blood samples from dams to assess thyroid hormones (T4, T3 and TSH) were not collected. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

4. Full summary

A teratogenicity study was conducted to evaluate the potential maternal and developmental toxicity of glyphosate in rats. The test substance was suspended in 0.5 % aqueous solution of sodium carboxymethylcellulose and was administered orally with stomach tube to 24 copulated Crj:CD (SD) female rats per group at dose levels of 0, 30, 300 or 1000 mg/kg bw/day from days 6 to 15 of gestation.

No adverse effects related to test substance treatment were observed for maternal rats in the 30 and 300 mg/kg bw/day groups. In the 1000 mg/kg bw/day group, 20 of 22 pregnant females showed slightly loose stool during the dosing period and/or on the following day of last dosing, and the incidence was statistically significantly high. No treatment related changes were observed in the body weights and body weight gains. Food consumption in this group was significantly decreased at an interval of days 6-9 of gestation (early dosing period).

Observation at cesarian section revealed no treatment related adverse effects in any of the parameters tested, i.e. gross pathology findings, gravid uterine weights, numbers of corpora lutea, implants and live foetuses, percent incidences of resorptions and foetal deaths, foetal sex ratio, foetal body weights and placenta weights.

In the teratological examination foetuses, no treatment related malformations or variations were noted in any of the treated groups.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:	Glyphosate technical
Identification:	HR-001
Description:	Solid white crystals
Lot/Batch #:	940908-1
Purity:	95.68 %
Stability of test compound:	Not mentioned in the report
Vehicle:	Purified water with 0.5 % sodium carboxymethylcellulose (CMC)
Test Animals:	
Species:	Rat
Strain:	SPF Crj:CD (SD)
Source:	[redacted]
Age:	13 weeks
Sex:	Females (males used for mating only)
Females weight at dosing:	267 - 322 g
Acclimation period:	11 days
Diet/Food:	Certified diet MF Mash (Oriental Yeast Co., Ltd.), *ad libitum*
Water:	Filtered and sterilised water, *ad libitum*
Housing:	Individually in aluminum cages with wire-mesh floors and fronts.
Environmental conditions:	Temperature: 24 ± 2 °C Humidity: 55 ± 10 % Air changes: 12/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates:
1995-03-23 to 1995-06-26

Mating procedure:
When animals were mated, pairs of males and females were housed, one pair per cage. Vaginal smears were taken from females for microscopic examination. Females showing proestrus or estrus vaginal smears were paired overnight with males on a 1:1 basis. The females were examined next morning for the presence of vaginal plugs and sperm in vaginal smears and considered to copulate when vaginal plugs and/or sperm

were observed. These mating procedures were repeated for 4 consecutive days.

Animal assignment
Four test groups were set; i.e. control, low-dose, middle-dose and high-dose groups. Copulated females were weighed on day 0 of gestation, the day in which evidence of copulation was detected, and distributed to 4 groups on that day in such a way to equalize group means and standard deviations of body weights. Each test group consisted of 24 copulated females which an individual animal number was given as follows: control group (1-24), low-dose group (25-48), middle-dose group (49-72) and high-dose group (73-96).

Dose selection rationale
The dose levels selected for this study were based on a dose range finding study in the pregnant rat. The highest dose level of 1000 mg/kg/day is the limit dose for this type of study.

Dose preparation and analyses
For each dose level, dosing solutions were prepared by suspending the specified amount of glyphosate acid in purified water with the aid of 0.5% sodium carboxymethylcellulose.

All dosing solutions prepared for each dose level were analysed for concentration of the test substance before use. For the first prepared dosing solutions, homogeneity of the test substance in vehicle was determined on the samples for the low- and middle-dose groups (30 and 1000 mg/kg/day, respectively) taken from the top, middle and bottom of the graduated glass cylinder immediately after preparation. Analytical data revealed that the test substance was distributed homogeneously in the vehicle.

Concentration analysis results: The achieved concentrations of glyphosate acid were detected at levels of 96-106% of the claimed concentrations in each dosing solution.
Homogeneity results: Analytical data revealed that the test substance was distributed homogeneously in the vehicle.
Stability results: The substance was stable in the 0.5% CMC solution for at least 14 days after preparation by the analysis conducted in the preliminary teratogenicity study ([redacted] 94-0139), dosing solution were therefore made twice at an interval of 7 days during this study.

Dose administration
The test substance was administered orally with a stomach tube to 24 copulated Crj:CD (SD) female rats per group at dose levels of 0, 300, 1000 mg/kg/day from day 6 to 15 of gestation. The volume of dosing solutions administered to females was 10 mL/kg body weight. Individual dosages were calculated based on the body weights on each day of dosing. During the dosing procedure, dosing solutions were constantly stirred with a magnetic stirrer to ensure homogeneity. Control animals only received the vehicle in the same manner.

Maternal Observations:
Clinical observations
Each female was observed for clinical signs and mortality at least once daily during the pre-dosing and post-dosing periods and at least twice daily during the dosing period.

Body weight
Individual body weights were recorded on days 0 (day on which evidence of copulation was recorded), 6-15 (daily during the dosing period) and 20 of gestation. Adjusted body weight gains were calculated by subtracting the gravid uterine weight from the body weight value on day 20 of gestation.

Food consumption
Food consumption of each female was determined at intervals of days 0-6, 6-9, 9-12, 12-15 and 15-20 of gestation.

Necropsy

All surviving females were euthanised by overdosage of ether inhalation and cesarian section was performed on day 20 of gestation.

Each female was necropsied. The ovaries and uterus were removed and the gravid uterine weight and numbers of copora lutea and implants were recorded. Then the uterus was opened and the numbers of live and dead foetuses were recorded with their positions in the uterine horns. When no uterine implants were grossly apparent, the uterus was stained with 10 % ammonium sulphide solution to detect very early resorptions.

Foetal observations

Resorbed embryos or dead foetuses were classified into implantation sites, placental remnants or macerated foetuses (including dead foetuses) according to developmental stage in which resorptions or deaths occurred. The weights of each live foetus and of each placenta were determined and recorded. Live foetuses were sexed and were euthanised by an intraperitoneal injection of pentobarbital sodium solution for examination of external abnormalities. The eyes were examined for alterations after removing the palpebral skin. Half of the foetuses were examined for visceral abnormalities according to the fresh visceral examination method. After examination, the foetuses were fixed and preserved in 10 % neutral-buffered formalin along with the ovaries and placentas. The other half of the foetuses were fixed in 70 % alcohol. Then they were eviscerated, stained with alizarin red S, cleared in 70 % glycerin, and examined for skeletal abnormalities. After examination, skeletal specimens were stored.

Statistics

Equality of variances was first evaluated using Bartlett's test for body weights, adjusted body weights, body weight gains and food consumption of maternal rats, numbers of corpora lutea, implants and live foetuses, and weights of gravid uteri, foetuses and placentas. When group variances were homogeneous, a parametric analysis of variance in one-way classifications was used to determine if any statistical difference exist among groups. If the analysis of variance was significant, Scheffé's multiple comparison test was performed to detect any statistically significant differences between the treated groups and their corresponding controls. When Bartlett's test indicated that the variances were not homogenous, Kruskal-Wallis test was used for detecting any statistical differences among groups and if significant, Scheffé-type mean rank test was performed to detect statistical differences between the treated groups and their corresponding controls. Fisher's exact probability test was used for the data on the incidences of clinical and gross pathological findings in maternal rats, incidences of maternal rats having foetuses with malformations and variations, incidences of foetal malformations and variations, and foetal sex ratio. Mann-Whitney's U-test was used for the data on the percent incidences of resorption and foetal deaths.

II. RESULTS AND DISCUSSION

A. MORTALITY

There were no mortalities during the study.

B. CLINICAL OBSERVATIONS

During the pre-dosing period, clinical observation revealed no abnormalities in any groups. During the dosing period, no abnormalities were observed in maternal rats of the control group. At 30 and 300 mg/kg bw/day, one or two maternal rats had hair loss or scabs on the skin which have been usually observed in the historical control rats. At 1000 mg/kg bw/day, 20 out of 22 pregnant females showed slightly loose stool and the increase in its incidence was statistically significant.

Table 5.6.2.2-01: Glyphosate technical: Teratology study in the rat ([redacted] 1995): Observed clinical signs during the dosing period (gestation days 6 through 15)

Clinical sign	Glyphosate technical (mg/kg bw/day)			
	0 (control)	30	300	1000
No. of animals examined	23 (1)	24 (0)	24 (0)	22 (2)
No abnormalities detected	23 (1)	23 (0)	22 (0)	2 (0)
Loose stool	0 (0)	0 (0)	0 (0)	20 (2)***
Hair loss	0 (0)	1 (0)	2 (0)	0 (0)
Scabs	0 (0)	0 (0)	1 (0)	0 (0)

Figures represent the number of animals which showed clinical signs during each period of the study.
Figures in parentheses represent the number of animals non-pregnant.
*** Significantly different from control at p<0.001.

During the post-dosing period, slightly loose stool was also observed on the following day of last dosing (day 16 of gestation) in 9 out of 20 females that showed this finding during the dosing period at 1000 mg/kg/bw/day. Another finding observed during this period was hair loss in 1-2 maternal rats in each treated group.

Table 5.6.2.2-02: Glyphosate technical: Teratology study in the rat ([redacted], 1995): Observed clinical signs during the post-dosing period (gestation days 16 through 20)

Clinical sign	Glyphosate technical (mg/kg bw/day)			
	0 (control)	30	300	1000
No. of animals examined	23 (1)	24 (0)	24 (0)	22 (2)
No abnormalities detected	23 (1)	23 (0)	22 (0)	13 (2)
Loose stool	0 (0)	0 (0)	0 (0)	9 (0)***
Hair loss	0 (0)	1 (0)	2 (0)	2 (0)
Scabs	0 (0)	0 (0)	0 (0)	0 (0)

Figures represent the number of animals which showed clinical signs during each period of the study.
Figures in parentheses represent the number of animals non-pregnant.
*** Significantly different from control at p<0.001.

Loose stool at highest dose level was considered to be due the test substance treatment.
No deaths occurred during the study in any groups.

C. BODY WEIGHT

No significant differences were found in the mean body weights and the mean adjusted body weights of maternal rats between the control groups and any of the treated group.

No significant differences were found in the mean body weight gains of maternal rats between the control group and any of the treated groups.

D. FOOD CONSUMPTION

No significant differences were found in the mean food consumption of maternal rats between the control group and any of the 30 and 300 mg/kg bw/day groups. In the 1000 mg/kg bw/day group, lower and higher values were observed in the mean food consumption at intervals of days 6-9 of gestation (early dosing period) and days 15-20 of gestation (post-dosing period), respectively, and the differences from the corresponding controls were statistically significant.

Table 5.6.2.2-04: Glyphosate technical: Teratology study in the rat ([redacted], 1995): Mean food consumption (g/day) of maternal rats

Dose level		Food consumption during gestation days				
mg/kg bw/day		0 - 6	6 - 9	9 - 12	12 - 15	15 - 20

E. NECROPSY

Gross pathological examination of maternal rats at cesarean section revealed several findings such as hair loss and pelvic dilatation in the kidney in 1-2 animals in all groups including the control group. These findings were not considered to be treatment related.

Table 5.6.2.2-05: Glyphosate technical: Teratology study in the rat ([redacted], 1995): Gross pathological findings in maternal rats

Gross pathological finding	Glyphosate technical (mg/kg bw/day)

	0 (control)	30	300	1000
No. of animals examined	23 (1)	24	24	22 (2)
No. abnormalities detected	20 (1)	21	19	20 (2)
Brain: Hydrocephalus	1 (0)	0	0	0 (0)
Spleen:				
Enlargement	0 (0)	0	1	0 (0)
Thickening of capsule	0 (0)	0	1	0 (0)
Spot(s)	0 (0)	0	1	0 (0)
Adhesion to omentum	0 (0)	0	1	0 (0)
Kidney: Pelvic dilatation	2 (0)	2	0	0 (0)
Skin: Hair loss	0 (0)	1	2	2 (0)

Figures in parentheses represent the number of animals non-pregnant.

Out of 24 copulated females, 23, 24, 24 and 22 were proved to be pregnant in the control, 30, 300 and 1000 mg/kg groups, respectively.

No significant differences were found in the mean gravid uterine weights and the mean numbers of corpora lutea and implants between the control group and any of the treated group.

F. FOETUSES

There were no significant differences in the mean number of live foetuses and the mean percent incidence of resorptions and foetal deaths between the control group and any of the treated groups. There were no significant differences in the foetal sex ratio, the mean foetal body weights and the mean placental weights between the control group and any of the treated group.

Teratological examination revealed external, visceral or skeletal malformations in 1-2 foetuses in all groups including the control group. These abnormalities, however, were low in their incidences and were considered to be spontaneous occurrences. Various visceral and skeletal variations were also observed in all groups including the control group. These alterations were not considered to be related to test substance treatment because of no significant differences in their incidences between the control group and the treated groups.

Findings in external, visceral and skeletal examination:
External malformations observed were short tail in a foetus of the 30 mg/kg bw/day group and microphthalmia in a foetus of the 1000 mg/kg bw/day group.

Visceral examination revealed two types of malformations: right aortic arch in a foetus of the 300 mg/kg bw/day group and ventricular septal defects in a foetus of each of the 300 and 1000 mg/kg bw/day groups.

Visceral variations were observed in all groups including the control group. The types and number in foetuses were thymic remnant in the neck, dilatation of the renal pelvis and left umbilical artery in 16-26, 1-2 and 0-3, respectively.

Skeletal examination revealed three types of malformations: splitting of the ossification centers of the thoracic vertebral bodies in 2, 1 and 2 foetuses in the control, 300 and 1000 mg/kg bw/day groups, respectively, asymmetry of the sternebrae with sterno-costal joint displacement in a foetus of the 300 mg/kg bw/day group, and fusion of the sternebrae in a foetus of the 300 mg/kg bw/day group, and fusion of the sternebrae in a foetus of the 1000 mg/kg bw/day group.

Skeletal variations were observed in all groups including the control group. The types and the number in foetuses were cervical ribs shortening of the 13th ribs, lumber ribs, sacralisation of the lumber vertebra and asymmetry and/or splitting of the sternebrae in 0-1, 0-1, 1-11, 0-1 and 3-5, respectively.

Table 5.6.2.2-07: Glyphosate technical: Teratology study in the rat ([redacted], 1995): Incidence of foetal malformation and variations

III. CONCLUSIONS

Based on slightly loose stool at the high dose, the NOAEL was set at 300 mg/kg bw/day for maternal rats, and 1000 mg/kg bw/day for developmental toxicity. It is also concluded that the highest dose level of 1000 mg/kg bw/day of glyphosate is not teratogenic to SD rat foetuses.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study using rats performed according to OECD 414 resulted in a NOAEL for maternal effects of 300 mg/kg bw/day based on slightly loose stool at the 1000 mg/kg bw/day dose level. The NOAEL for developmental toxicity was considered to be 1000 mg/kg bw/day. Teratogenic effects were not observed.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/003**
Report author	[redacted]
Report year	1991
Report title	The effect of glyphosate on pregnancy of the rat (incorporates preliminary investigation)

Report No	CHV 43 & 41/90716
Document No	Not reported
Guidelines followed in study	U.S. EPA FIFRA Guidelines 83-3, 1989; OECD Guideline 414, 1981
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: weight and histopathological changes of the thyroid glands of the dams, anogenital distance (AGD) in foetuses, indication of incomplete testicular descent/cryptorchidism in male foetuses. Blood samples from dams to assess thyroid hormones (T4, T3 and TSH) were not collected. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. **Full summary**

A teratogenicity study was conducted to evaluate the potential maternal and developmental toxicity of glyphosate technical in rats. The test substance was suspended in 1 % aqueous solution of methylcellulose and was administered orally, by gavage, to 25 mated Crl:CD (SD) female rats per group at dose levels of 0, 300, 1000 or 3500 mg/kg bw/day on Days 6 to 15 of gestation.

Mortality was confined to the highest dose and clinical signs of toxicity were observed at the two upper dose levels. Two high dose females were sacrificed on day 7 and 13, respectively, following noisy respiration and gasping. Since respiratory signs were apparent in most animals of this group and in few cases at the mid dose level, these deaths were considered treatment-related. One more high dose dam was killed just after a probable intubation error. Post-dosing salivation and loose faeces were further symptoms observed among animals receiving 3500 mg/kg bw/day. During the first two days of treatment, body weight gain was reduced at the high and, although only to a marginal extent, at the mid dose level. Food consumption was slightly decreased in the high dose group during the dosing period but was comparable with controls thereafter. Water intake was increased at 3500 mg/kg bw/day. Necropsy at termination did not reveal findings which could be attributed to treatment.

There were no abortions and no total resorptions. Implantation rate, post-implantation loss, litter size and sex ratio were similar in all groups. The only effect was a reduction in mean foetal weight at 3500 mg/kg bw/day. The occurrence of malformations was not significantly increased by treatment. However, the incidence of rib distortion (wavy ribs) was markedly higher in the high-dose group. In addition, reduced ossification was seen slightly more frequently at this dose level and also at 1000 mg/kg bw/day. As result, the percentage of foetuses showing skeletal anomalies (variations) was significantly increased at the mid- and high-dose levels. However, the percentage for the mid-dose level only slightly exceeded the historical background range (21.9 - 27.2 %) whereas the respective control value was atypically low in this study.

Treatment with glyphosate at 300 mg/kg bw/day was without adverse effect on maternal or embryofoetal parameters.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:	Glyphosate technical
Description:	White solid
Lot/Batch #:	206-Jak-25-1
Purity:	98.6 %
Stability of test compound:	At least five years
Vehicle:	Purified water with 1% sodium methylcellulose (MC)
Test Animals:	
Species:	Rat
Strain:	SPF Crl:CD (SD) BR VAF/Plus strain
Source:	[redacted]
Age:	8-10 weeks
Sex:	Females
Weight at dosing:	251 - 258 g (mean group values)
Acclimation period:	11 days
Diet/Food:	Labsure Laboratory Animal Diet No. 1, *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	In groups of five in suspended galvanised metal cages equipped with solid sides and back, wire mesh front, floor and top.
Environmental conditions:	Temperature: 21.0 – 25.0 °C Humidity: 39 – 64 % Air changes: not reported 12 hours light/dark cycle

B. STUDY DESIGN

In life dates
1989-11-16 to 1989-12-12

Mating procedure
Time-mated animals were received from the breeder in two batches (A and B). The day of mating, as judged by appearance of sperm in a vaginal smear or by presence of a vaginal plug was considered as Gestation Day 0.

Animal assignment
Animals were assigned to four groups using arrival weights by computerised stratified randomisation to give approximately equal initial group mean body weights within each batch. Each test group consisted of 25 females (10 in batch A and 15 in batch B) which an individual animal number was given as follows: control group (1-25), low-dose group (26-50), middle-dose group (51-75) and high-dose group (76-100).

Dose selection rationale
The dose levels selected for this study were based on a dose range finding study in the pregnant rat. The highest dose level of 1000 mg/kg/day is the limit dose for this type of study.

Dose preparation and analyses
The highest dose formulation was prepared by suspending an appropriate amount of test substance in 1 % aqueous methylcellulose. Dose formulation for the lower dose groups were prepared by serial dilution with

1% methylcellulose. Formulations were prepared daily and used within three hours of preparation. Samples were taken for analysis on the first day of treatment for each of the two batches of animals.

Concentration analysis results: The achieved concentrations of glyphosate acid with the exception of one result (Batch A, Group 4) which was 17.4 % above the nominal concentration, mean results were within 5 % of nominal values.
Homogeneity results: Analytical data revealed that the test substance was distributed homogeneously in the vehicle.
Stability results: The substance was stable in the 1 % aqueous methylcellulose solution for at least 72 hours after preparation.

Dose administration
The test substance was administered orally, by gavage, to 25 mated female rats per group at dose levels of 0, 300, 1000 and 3500 mg/kg bw/day from day 6 to 15 of gestation. The dose volume was 1 mL/100 g bw. Dose volumes were calculated for individual animals on day 6 and adjusted according to body weight on days 8, 10, 12 and 14.

Maternal Observations:
Clinical observations
Each female was observed daily for mortality, obvious changes and reaction to treatment.

Body weight
Individual body weights were recorded initially (day 1) and on days 3, 6, 8, 10, 12, 14, 16, 18 and 20 of gestation.

Food consumption
Food consumption of each female was determined at intervals of days 1-3, 3-6, 6-8, 8-10, 10-12, 12-14, 14-16, 16-18 and 18-20 of gestation.

Water consumption
Water consumption was determined daily from day 2 through to termination.

Necropsy
All surviving females were euthanised by CO_2 asphyxation, dissected and examined for congenital abnormalities and macroscopic pathological changes in maternal organs. Abnormal tissues were preserved at the discretion of the *post mortem* pathologist. The ovaries and uteri were examined immediately to determine the number of corpora lutea, number and distribution of live young, number and distribution of embryofoetal deaths.

Foetal observations
Embryofoetal deaths were classified as early (only placenta visible) or late (both placental and embryonic remnants visible). Uteri or individual uterine horns without visible implantations were immersed in a 10% solution of ammonium sulphide to reveal evidence of embryonic death at very early stages of implantation. Live young were examined externally, weighed and individual identified. Approximately half the foetuses in each litter were preserved in Bouin's solution for subsequent free-hand sectioning to discover visceral abnormalities (Wilson technique); the remainder were fixed in 74 OP industrial methylated spirit for subsequent macroscopic examination, evisceration, clearing and alizarin staining (modified Dawson technique) for skeletal examination. Young showing suspected abnormalities were processed by the more appropriate technique for clarification of initial observations. All foetuses were sexed by gonadal inspection following preservation.

Statistics
Group values: Group mean values, except for food and water consumption, were calculated using only animals with live young at termination. As animals were group-housed, food and water consumption values

are based on all animals regardless of pregnancy status.

Statistical analyses were routinely performed on litter data. Significance tests were normally two-tailed. The basic sample unit was the litter. Mean values of litter size, pre- and post-implantation loss, litter weight, mean pup weight and the incidence of anomalous offspring were analysed by the Kruskal-Wallis test followed, if significant, by the non-parametric equivalent of Williams' test for intergroup comparison with the control. Where 75 % of the values for a given variable consisted of one value. A Fisher's exact test was used.

II. RESULTS AND DISCUSSION

A. MORTALITY

At 3500 mg/kg bw/day, one female was sacrificed on Day 10 of pregnancy immediately after dosing following a probable intubation error (white fluid was found in the thoracic cavity). A further two females were sacrificed on day 7 and 13, respectively, following signs of respiratory distress (noisy respiration/gasping). *Post mortem* observation did not reveal the cause of distress, but the marked signs were a continuation of the signs representative for this group and these two deaths are considered to be related to treatment. There were no further deaths.

B. CLINICAL OBSERVATIONS

Signs of reaction to treatment at 3500 mg/kg bw/day amongst survivors included post-dose salivation in all animals with wet coats observed in approximately half the animals. Loose faeces on the cage traypaper were seen from day 7 or 8 of pregnancy and persisted throughout the treatment period. Noisy respiration and/or gasping were observed in 17/22 females on one or more occasions. At 1000 mg/kg bw/day, two animals showed noisy respiration on one occasion. There were no clinical signs observed at 300 mg/kg bw/day.

Table 5.6.2.3-01: Glyphosate technical: Teratology study in the rat ([redacted], 1991): Summary of maternal performance and clinical signs

Clinical sign	Glyphosate technical (mg/kg bw/day)			
	0 (Control)	300	1000	3500

Noisy respiration	0	0	2	15
Wet coats	0	0	0	13
Gasping	0	0	0	5
Area of hair loss/scabbing	2	3	3	0

C. BODY WEIGHT

At 3500 mg/kg bw/day, the rate of body weight gain was markedly reduced during the first two days of treatment when compared to the concurrent control values. Thereafter, apart from a slight reduction in the rate of body weight gain during days 12 to 14 of pregnancy, the rate of body weight gain was comparable with the controls, although absolute parity with the control group was not attained by day 20. At 1000 mg/kg bw/day, there was a marginal reduction in the rate of body weight gain during the first two days of treatment

when compared with the concurrent control group. Thereafter, the pattern of body weight change was similar to the controls. At 300 mg/kg bw/day, the pattern of body weight gain was generally similar to controls throughout.

Table 5.6.2-3: Glyphosate technical: Teratology study in the rat ([redacted], 1991): Mean body weights (g) and body weight gain (g) relative to start at treatment on Day 6

Day 20	163.9	159.5	152.1	132.6

D. FOOD CONSUMPTION

At 3500 mg/kg bw/day, food consumption was decreased throughout the treatment period, thereafter, food intake was comparable with controls to termination. At lower dosages, food consumption was comparable with controls throughout.

E. NECROPSY

Among animals killed at day 20, the only macroscopic finding was hair loss/scabbing in occasional animals, including controls, and was not related to the test item.

Out of 25 mated females, 23, 23, 25 and 22 had live young at day 20 in the control, and 300, 1000 and 3500 mg/kg bw/day groups, respectively. There were no instances of total resorption in any group. There were no treatment-related effects on the implantation rate, embryonic or foetal losses. There was an apparent increase in pre-implantation loss at 3500 mg/kg bw/day but since treatment commences after implantation, this is not considered to be treatment-related.

F. FOETUSES

There were no significant differences in the mean number of litter size.

At 3500 mg/kg bw/day, both litter and mean foetal weights were reduced in comparison with controls with differences from control values for mean foetal weight attaining statistical significance. At lower dosages, the slight differences observed were not considered to be attributable to treatment.

There were no significant differences in foetal sex ratios between the control group and any of the treated groups.

Table 5.6.2-5: Glyphosate technical: Teratology study in the rat ([redacted], 1991): Litter data – group mean values

** Statistically significant difference from control group mean (Kruskal-Wallis H-statistic followed, if significant, by intergroup comparison with the control (distribution-free Williams' test, significant at $p<0.01$)

Findings in external, visceral and skeletal examination:
A total of 1, 2, 1 and 3 foetuses in Groups 1 to 4 respectively were malformed; this low incidence does not suggest any treatment-related aetiology. The incidence of foetuses with visceral anomalies was low and did not indicate any adverse treatment-related effects. The only skeletal change clearly influenced by treatment was rib distortion (wavy ribs) for which the incidence was markedly increased at 3500 mg/kg bw/day. The marginally higher incidence at 1000 mg/kg bw/day was of uncertain relationship to treatment. The only other skeletal change considered worthy of mention was reduced ossification for which the incidence was higher in all treated groups compared to the concurrent control. However, as comparison with the background control data showed the incidence of these skeletal changes at 3500 mg/kg bw/day to be only slightly outside the expected range, and no clear dosage-response was apparent, the effect on these skeletal changes (reduced ossification) were not considered to be attributable to treatment with the test item.

III. CONCLUSIONS

Within the context of this study, glyphosate shows obvious effects on maternal parameters and embryofoetal development at 3500 mg/kg/day (although does not induce malformations), and shows slight maternal effects at 1000 mg/kg/day. It can be concluded that glyphosate shows no selective embryofoetal toxicity and that the no-effect-level for embryofoetal development is 1000 mg/kg/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this developmental toxicity study according to OECD 414, the maternal NOAEL was set at 300 mg/kg bw/day based on mortality, clinical signs, decreased body weight gain and reduced food and water intake indicating a clear adverse effect of glyphosate administration at 3500 mg/kg bw/day and a possible impact at 1000 mg/kg bw/day with noisy respiration and decreased body weight gain. There was no evidence of teratogenicity in this study. Secondary to maternal toxitcity, reduced foetal weight, delayed ossification and a lower number of viable foetuses was observed at the extremely high top dose of 3500 mg/kg bw/day and reduced/delayed ossification and increased incidence of skeletal variations were observed at 1000 and 3500 mg/kg bw/day. The developmental NOAELwas considered to be 300 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.6.2/004
Report author	[redacted]
Report year	1991
Report title	Teratogenicity study in Wistar rats
Report No	ES.883.TER-R
Document No	Not reported
Guidelines followed in study	Not stated but in general accordance with OECD Guideline 414, 1981
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: weight and histopathological changes of the thyroid glands of the dams, anogenital distance (AGD) in foetuses, indication of incomplete testicular descent/cryptorchidism in male foetuses. Blood samples from dams to assess thyroid hormones (T4, T3 and TSH) were not collected. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

A teratogenicity study was conducted as a limit test to evaluate the potential maternal and developmental toxicity of glyphosate technical in rats. The test substance was suspended in groundnut (peanut) oil and was administered orally, by gavage, to 20 mated female Wistar rats at a dose level of 1000 mg/kg bw/day on days 6 to 15 of gestation. Thirty control rats received the vehicle, refined groundnut (peanut) oil. Both groups received a dose volume of 5 mL/kg bw. The limit dose of 1000 mg/kg bw/day had been selected on the basis of preliminary tests which were also briefly described in the main study report. Investigations were carried out according to OECD guideline 414 (1981). Appropriate statistical methods were applied.

There was no evidence of maternal toxicity. Mortality and clinical signs of toxicity were not noted. Body weight, body weight gain and food intake were not impaired. There was no impact on reproduction indices or litter data. The incidence of foetal malformations was not increased in the treated group compared to the control. There was limited evidence of a higher incidence of delayed ossification (caudal vertebral arch, forelimb proximal and hindlimb distal phalanges) in the group receiving glyphosate. On the other hand, delayed ossification of other parts of the skeleton, in particular the skull, was more frequently seen in the control group. Thus, there was no clear and consistent impact of test compound administration on the process of ossification.

Glyphosate technical, when administered at a limit dose of 1000 mg/kg bw/day from day 6 to 15 of gestation did not induce maternal or embryofoetal toxicity and no teratogenic potential was observed.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:	Glyphosate technical
Description:	Solid white coloured crystal, odourless
Lot/Batch #:	60
Purity:	98.6 %
Stability of test compound:	Minimum 2 years under normal conditions
Vehicle:	Postman brand refined groundnut (peanut) oil
Test Animals:	
Species:	Rat
Strain:	Wistar
Source:	[redacted]
Age:	approx.18-20 weeks
Sex:	Females
Weight at dosing:	199 - 200 g (mean group values)
Acclimation period:	At least 10 days
Diet/Food:	Pelleted rat feed from M/S Lipton India Ltd., *ad libitum*
Water:	Protected, deep borewell water, passed through activated charcoal filter and exposed to UV rays in Aquagard on-line water filter cum-purifier, provided in glass bottles, *ad libitum*

Housing:	After mating: single housing in polypropylene rat cages; clean sterilised paddy husk bedding.
Environmental conditions:	Temperature: 22 ± 3 °C
	Humidity: 67 %
	Air changes: 10-15 per hour
	12 hours light/dark cycle

B. STUDY DESIGN

In life dates: November 1990 to December 1990

Mating procedure: In the final study randomly selected 1 male: 3 females were cohabited overnight. When a vaginal plug or spermatozoa were found in the vaginal smear the next morning, that day was considered day 0 of pregnancy.

Animal assignment: The day '0' pregnant rats were assigned to a single group until there were 35 rats in 0 mg/kg group and 25 rats in the 1000 mg/kg bw/day group.

Dose selection rationale: The dose levels selected for this study were based on two dose range finding studies, one in non-pregnant and one in pregnant rats. In the first study, groups of 3 non-pregnant rats were treated orally, by gavage, at 100, 400 and 1000 mg/kg bw/day for 10 consecutive days. Three female rats received the vehicle only, and served as the control group. No mortalities occurred during this study. No clinical signs were noted in the control and low dose animals. At 400 mg/kg bw/day one animal appeared emaciated; at 1000 mg/kg bw/day emaciation, urinary incontinence and red nasal discharge were noted for one animal. Body weight gain was unaffected up to and including 400 mg/kg bw/day but was slightly reduced at 1000 mg/kg bw/day (- 5.1% compared to the control).
Feed intake was not affected up to 1000 mg/kg bw/day.

In the second range finding study, 5 mated rats were treated orally, by gavage, at 1000 mg/kg bw/day from day 6 until day 15 of gestation. Historical control data from 70 animals were used as reference data. No mortalities occurred during this study. At 1000 mg/kg bw/day, urinary incontinence was noted in two animals and loose stool was noted for one animal. Body weight gain in test item-treated animals was slightly reduced (67.2 % compared to 75.0 % in the historical control), while feed intake was similar to that of the historical control (13.5 g/rat/day versus 15.0 g/rat/day in the control). At caesarean section on day 20 of gestation no effects of treatment were noted.

Dose preparation and analyses: A known amount of test compound was weighed, ground using a mortar and pestle and suspended in a known volume of the groundnut oil to get the concentrations of 0 and 1000 mg/kg in 5 mL of the vehicle. Fresh suspension of the test compound was prepared for administration each day. Analysis of dose formulations is not reported.

Dose administration: The test substance was administered orally by gavage.

Maternal Observations:
Clinical observations: Each female was observed twice daily for mortality, obvious changes and reaction to treatment.

Body weight: Individual body weights were recorded of all rats prior to mating. Mated rats were weighed on day 0 and daily from day 6 to 15 and on day 20. From these values the body weight gain was calculated for the following intervals: days 0-6, 6-15, 15-20 and 0-20. Corrected body weight was derived by subtracting gravid uterus weight from day 20 body weight.

Food consumption: Food consumption of each female was determined at intervals of days 0-6, 6-16, and

16-20 and throughout gestation day(days 0-20).

Necropsy: All females included in the study, dead moribund and terminally sacrificed were subjected to gross pathology. Tissues with gross lesions were preserved for histopathological examination if deemed necessary. On day 20 all surviving rats were sacrificed under ether anaesthesia and subjected to caesarean section. The abdomen was opened, and the uterus exposed. The uterus along with the ovaries was excised and weighed. The following observations were made: uterine weight, number of corpora lutea, number of implantations, embryonic and foetal resorptions.

Foetal observations: The following foetal data were recorded: total number of foetuses, number of dead foetuses, number of abnormal foetuses, number of live foetuses (including foetal weight), number of male foetuses, number of male foetuses, sex ratio. All foetuses were examined for external malformations, sex and weight. Afterwards foetuses were killed using excess ether anaesthesia. Approximately half the foetuses in each litter were fixed in 70 % ethanol and examined by modified Wilson's technique. Visceral malformations recorded were categorised as normal variants, minor and major malformations. The remaining half of the foetuses were fixed in 70 % ethanol, skinned, eviscerated, dehydrated in 95 % ethanol, macerated in 2 % KOH and stained with Alizerin Red-S in Mall's solution. The stained foetuses were cleared in grades of glycerol and evaluated for skeletal malformations. The malformations recorded were classified as normal variants, minor and major malformations.

Statistics: For statistical analysis the litter was used as the basic sampling unit. The following statistical methods were used:
1) Maternal body weight and body weight gain, food intake, no. of corpora lutea, no. of implantations, mean foetal weight by Bartlett's test followed by ANOVA and Dunnett's test with statistical significance at P=0.05.
2) Day 0 and absolute body weight by paired t-test.
3) Litter size by Student's t-test
Sex ration, no. of rats with resorptions, no. of rats with complete resorption, incidence of malformations by 2 x 2 contingency table.
Results of statistical analyses are designated as significantly higher (+) /lower (-) than control value at P=0.05.

II. RESULTS AND DISCUSSION

A. MORTALITY
No mortality occurred in this study.

B. CLINICAL OBSERVATIONS
Common clinical signs seen in a few animals in the study groups were: weakness and dullness, soft faeces, red coloured nasal discharge, snuffling, lacrimation and urinary incontinency. Their incidence was similar in both the control and test item group.

Table 5.6.2-10: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of clinical signs

Clinical sign	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
No. of animals in group	30	20
Mortality	0	0
Clinical signs		
Weak, dull	2	0
Soft faeces	2	2

Nasal discharge	2	4
Red coloured nasal discharge	2	0
Lacrimation	0	1
Urinary incontinency	1	1
Snuffling	6	3

C. BODY WEIGHT

There were no statistically significant differences in body weight throughout the study. The mean body weight gain during pre-treatment, treatment, post-treatment or the overall gestation period did not show any statistically significant differences between the control and the treated group. Similarly, corrected body weight gain at the end of gestation was significantly increased (P=0.01) in both groups compared to day 0 weights.

Table 5.6.2-11: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Mean body weights and corrected body weight gain (g) relative to start at treatment on day 6 (group means ± SD)

Parameter	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
Mated females	35	25
No. of animals included in assessment (pregnant at term)	30	20
Body weights at		
Day 0	186 ± 18.5	188 ± 13.9
Day 6	199 ± 18.2	200 ± 16.5
Day 15	218 ± 19.7	220 ± 17.6
Day 20	258 ± 27.2	253 ± 30.2
Corrected body weight gain (Day 20 bw – uterine weight)	208 ± 23.3	210 ± 21.6

D. FOOD CONSUMPTION

There were no intergroup differences in food consumption between treated and control groups. Statistically significantly lower food consumption was noted in the treated group during the pre-treatment period.

Table 5.6.2-12: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of food consumption (group means ± SD)

Parameter	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
Mated females	35	25
No of animals included in assessment (pregnant at term)	30	20
Food consumption (g/rat/day) during		
Days 0-6	17 ± 2.1	15 ± 2.4*
Days 6-16	15 ± 1.9	15 ± 2.0

Days 0-20	16 ± 1.9	16 ± 2.1

* Significantly lower compared to the control (Dunnett's test, P=0.05)

E. NECROPSY

Dams necropsied during the study showed stray incidence of petechiae, emphysema, congestion, focal consolidation of lung and higher incidence of mottled liver. These incidences did not show any relationship with the test item.

The number of corpora lutea, implantations, embryonic and foetal resorptions, pre-implantation and post-implantation loss were similar in both groups. The number of dams with any resorption was lower in the treated group than in the control, which was considered an incidental finding.

Table 5.6.2-13: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of maternal performance and litter data (group means ± SD)

Observation	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
No. animals assigned (mated)	35	25
No. animals with live young on Day 20	30	20
No. pregnancy status not determined (intercurrent sacrifice)	0	0
No. of corpora lutea	11 ± 1.7	11 ± 2.0
No. of implantations	10 ± 2.5	9 ± 3.2
Pre-implantation loss (%)	38 (13)	35 (20)
No. of embryonic resorptions (%)	24 (8)	19 (11)
No. of foetal resorptions (%)	0 (0)	0 (0)
Post implantation loss (%)	24 (8)	19 (11)
No. of dams with any resorptions (%)	15 (50)	11 (55)
No. of dams with total resorption (%)	0 (0)	0 (0)
Total no. of foetuses	261	157
Mean litter size	9	8
No. of dead foetuses/litter	0	0
No. of abnormal foetuses	0	0
Mean foetal weight (g)	3.6 ± 0.4	3.7 ± 0.3
Foetal sex ratio (male:female)	1:1	1:1.3

F. FOETUSES

There were no significant differences in litter size or the incidence of dead or abnormal foetuses.

No differences between the test item group and the control were noted for foetal body weights or foetal sex ratios.

Findings in external, visceral and skeletal examination:

At external examination, the incidence of normal variations like haemorrhagic spots was slightly higher in the treated group than in the control. However, the difference was not statistically significant. Incidences of minor malformations like small foetus was noted in both groups. There was one incidence of a foetus with short snout in the control group. No incidence of major external findings was noted in either of the study groups.

Table 5.6.2-14: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of foetal external findings (% foetuses affected)

Observation	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
No. of foetuses examined	261	157
No. of litters examined	30	20

Variations		
Haemorrhagic spot	5.4	10.2
Minor Malformations		
Foetus small	0.8	0.6
Snout short	0.4	0.0
Major Malformations		
No. of foetuses with major malformations	0	0

Visceral examination and intergroup statistical comparison of visceral findings revealed that the incidence of variations like tortuous ureter was noted in the control and treated group. A few incidences of minor malformations seen in both the control and treated group were unascended kidney, slight renal pelvis dilation, unusual lung lobulation, retinal folding, displacement of umbilical artery and displacement of vitelline vein. None of these observations reached the level of statistical significance. No major visceral malformations were noted.

Table 5.6.2-15: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of foetal visceral findings (% foetuses affected)

Observation	Glyphosate technical (mg/kg bw/day)	
	0 (control)	1000
No. of foetuses examined	122	74
No. of litters examined	30	20
Variations		
Ureter - tortuous	35.3	31.1
Minor Malformations		
Testis - undescended	1.6	0.0
Renal pelvis – slight dilation	5.7	4.0
Uterus - short	1.6	0.0
Lung – unusual lobulation	0.0	1.4
Retinal folding	0.8	0.0
Umbilical artery - displaced	0.8	0.0
Vitelline vein - displaced	0.0	1.4
Major Malformations		
No. of foetuses with major malformations	0	0

The incidence of variations like delayed ossification was noted in many bones, both in the control and treated group. However, the incidence of delayed ossification of caudal vertebral arch, forelimb-proximal phalanx and hindlimb-distal phalanx was significantly higher in the treated group compared to the control. However, the incidence of incomplete to partial ossification of parietal and interparietal of the skull was less in the treated group. The incidence of minor and major skeletal malformations present to a small extent in both groups, did not show any statistically significant intergroup differences.

Table 5.6.2-16: Glyphosate technical: Teratogenicity study in Wistar rats ([redacted] 1991): Summary of foetal major skeletal malformation findings (% foetuses affected)

Observation		Glyphosate technical (mg/kg bw/day)	
		0 (control)	1000
No. of foetuses examined		140*	83
No. of litters examined		30	20
Major Malformations			
Malformed	Supraoccipital bone	0.7	0.0
	Parietal bone	0.7	2.4

	Interparietal bone	2.1	3.6
	Temporal bone	0.7	1.2
	Basisphenoid	1.4	1.2
	Sternebra #6	0.0	1.2
	Cervical vertebral arch # 3-7	0.7	0.0
	Scapula	0.7	0.0
Incomplete	Palatine	0.0	2.4
	Zygomatic arch	2.1	0.0
	Cervical vertebral arch #5	0.7	0.0
	Cervical vertebral arch #6	1.4	0.0
Fused	Sternebrae #1-6	0.7	0.0
No. of foetuses with major malformations		17	10
No. of dams with foetuses with major malformations		8	6

* One foetus noted with short snout during visceral examination was also evaluated for skeletal changes

III. CONCLUSIONS

Glyphosate technical, when administered at a limit dose of 1000 mg/kg bw/day from day 6 to 15 of gestation did not induce maternal or embryofoetal toxicity and no teratogenic potential was observed. Accordingly, the NOAEL for maternal and embryofoetal toxicity was 1000 mg/kg bw/day.

5. Assessment and conclusion

Assessment and conclusion by applicant:

This study (performed according to OECD 414) showed no evidence of maternal toxicity. The incidence of foetal malformations was not increased in the treated group compared to the control. There was limited evidence of a higher incidence of delayed ossification (caudal vertebral arch, forelimb proximal and hindlimb distal phalanges) in the group receiving glyphosate. On the other hand, delayed ossification of other parts of the skeleton, in particular the skull, was more frequently seen in the control group. Thus, there was no clear and consistent impact of test compound administration on the process of ossification. Thus, the NOAEL for both maternal and developmental toxicity is assumed to be 1000 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/006**
Report author	[redacted]
Report year	1986
Report title	Report on effect of glyphosate technical of Excel Industries Ltd. Bombay, India; on reproductive process. Segment II – Teratological study
Report No	Not indicated
Document No	Not indicated
Guidelines followed in study	Not mentioned in Monograph (2000)
GLP	No (not compulsory at that time)

Previous evaluation	Yes. The study was evaluated and not accepted (Monograph 2000).
Short description of study design and observations:	20 mated female Wistar rats per group were administered glyphosate (Excel Industries Ltd. Bombay, India; purity not reported) at dose levels of 0 (control, vehicle not stated), 100 and 500 mg/kg bw/day on gestational days 6 through 15 by gavage. Dams were sacrificed and foetuses delivered on day 20.
Short description of results:	Neither maternal nor reproduction and embryo-foetal effects were observed up to the highest dose tested. Thus, the NOEL for both maternal and developmental toxicity was 500 mg/kg bw/day in this study.
Reasons for why the study is not considered relevant/reliable or not considered as key study:	The study was considered not acceptable due to several serious reporting deficiencies.
Reasons why the study report is not available for submission	The notifier has no access to this study report. Since the study was part of the earlier data package available to the former RMS of the active substance glyphosate, the AGG would have to send a "request for administrative assistance" (Art. 39 of Regulation (EC) No. 1107/2009) to the BVL

3. Full summary

In this developmental toxicity study, groups of 12-15 time-mated female CFY rats were administered glyphosate from Days 6 to 18 of gestation as a dietary admix. In both, the control and high dose group 10 additional females were treated and allowed to give birth and raise their litters until day 28 post partum ('postnatal group'). Concentrations of glyphosate in the diet are not reported, but from Days 6 to 18 of gestation admix of the test item was reported to result in to test item intakes of 22, 103 and 544 mg/kg bw/day, respectively. For the high dose postnatal females a test item intake of 558 mg/kg bw/day was reported. Females of the 'prenatal group' were sacrificed in a CO_2 chamber on Day 20 of gestation. After opening the uterine horns the total number of implantations, of live, dead and resorbed embryos/foetuses were counted. The mean litter and foetal weights, gestational growth, the mean body weight gain and food consumption were calculated. Live foetuses in the prenatal groups were fixed and examined for visceral and skeletal abnormalities. The following foetal organs were examined histologically: heart, lungs, thymus, liver, intestines, pancreas, spine, skeletal muscles, intervertebral discs and nervous tissue.

Females of the postnatal group and their offspring were sacrificed on day 28 post partum. Gross and histopathology was conducted on each animal. The following organs were histopathologically examined: heart, lungs, thymus, stomach, liver, kidney, spleen and reproductive organs.

Treatment with glyphosate had no effect on the maternal organism. Body weight was similar in the treated groups, body weight gain in the mid and high dose group was slightly lower than in controls throughout pregnancy, gross examination and histopathology carried out on foetuses of the 'prenatal group' indicated no changes in any group. In the postnatal group no toxic symptoms or gross pathology alterations were observed in high dose or control females; and no macroscopic or microscopic changes were noted in their offspring.

Based on these results the non-teratogenic level is larger than 544 mg/kg bw/day.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate /active principle
Description:	White odourless adhesive powder
Lot/Batch #:	Not stated
Purity:	96.8 %
Stability of test compound:	Not stated
Vehicle:	Laboratory rodent food

Test Animals:

Species:	Rat
Strain:	CFY
Source:	Not stated
Age:	Not stated
Sex:	Female
Weight:	210-275 g (group mean values)

Acclimation period:	Not stated	
Diet/Food:	Laboratory rodent food, *ad libitum* (before and after the treatment period)	
Water:	*ad libitum*	
Housing:	Individually, in plastic cages	
Environmental conditions:	Temperature:	22 ± 2 °C
	Humidity:	55-75 %
	Air changes:	8 per hour
	Light regime	12/12 hours

B. STUDY DESIGN

In-life dates
Not stated.

Mating procedure
In this developmental toxicity study two female rats and one male rat were housed in the same cage for mating; the males were changed every second day. To detect mating the presence of sperm in native vaginal smears was checked daily; the presence of vaginal plugs was recorded.

Animal assignment
Groups of 12 - 15 mated female CFY rats were assigned to four dose groups in the prenatal part of the study. An additional 10 females were added to the control and high-dose groups and were assigned to be the postnatal part of the study.

Dose selection rationale
Not provided.

Dose preparation and analyses
Not provided.

Dose administration
Treatment was via the dietary route. Concentrations of glyphosate in the diet are not reported, but from days 6 to 18 of gestation admix of the test item had reported intakes of 22, 103 and 544 mg/kg bw/day, respectively. For the high-dose postnatal females a test item intake of 558 mg/kg bw/day was reported.

Maternal Observations:
Clinical observations: Not stated.

Body weight
Individual body weights were generally recorded daily during gestation and lactation. However, not on every day body weights were recorded for all animals.

Food consumption
Not stated.

Necropsy

Prenatal group
Females were sacrificed in a CO_2 chamber on day 20 of gestation. After opening the uterine horns the total number of implantations, of live, dead and resorbed embryos/foetuses were counted. The mean body weight

gain and food consumption were calculated.

Postnatal group
Females and their offspring were sacrificed on day 28 *post partum*. Gross and histopathology was conducted on each animal.

Foetal observations
The mean litter and foetal weights and gestational growth were recorded. Half of the live foetuses in the prenatal groups were fixed in 4 % neutral formalin and embedded in paraffin. Sagittal sections of 5-8 µm were prepared. Cerebral, abdominal, thoracal morphological abnormalities were examined by Wilson technique. In the other half of foetuses, skeletal abnormalities were examined according to Simon and Hern (1971). The following foetal organs were examined histologically in the prenatal group: heart, lungs, thymus, liver, intestines, pancreas, spine, skeletal muscles, intervertebral discs and nervous tissue. The following foetal organs were histopathologically examined in the postnatal group: heart, lungs, thymus, stomach, liver, kidney, spleen and reproductive organs.

Statistical analyses
Group means and deviations were calculated according to Finney (1952).

II. RESULTS AND DISCUSSION

A. MORTALITY
None.

B. CLINICAL OBSERVATIONS
No effect on behaviour or appearance was observed in either the prenatal or postnatal dams.

C. BODY WEIGHT
Body weight gain was similar in the treated prenatal groups compared to control; when the gestation period (day 1-20) is considered the body weight gain in the mid- and high-dose groups were slightly below the control level. In the postnatal group the body weight gain was similar in the treated high-dose group compared to control (when using the recalculated value).

Table 5.6.2-17: Glyphosate technical: Teratological investigation of glyphosate in rats and rabbits ([redacted] 1981): Summary of body weight data (group means) - Prenatal group

Parameter	Glyphosate (mg/kg bw/day)

[1] in the report, an obviously wrong value of 73 g is given; recalculation resulted in the presented value
[2] weighing day for the control/weighing day for the high dose

D. FOOD CONSUMPTION
Not reported.

E. NECROPSY
No macroscopic changes were noted in the control and glyphosate-treated females in either the prenatal or postnatal groups.

F. FOETUSES
A total of 13, 12, 15 and 15 pregnant females from the prenatal group survived to termination and 134, 134, 192 and 185 live foetuses were recorded for the 0 (control), 22, 103 and 544 mg/kg bw/day dose groups, respectively. There were no significant intergroup differences in the numbers of implantations (see table below). The incidence of dead foetuses was slightly higher in the mid-dose group than in the controls but without a dose response. The percentage of foetal loss was highest in the control group while for the high-dose group the lowest values were noted. No total litter loss was recorded in any group. Litter size at caesarean necropsy was comparable in all treatment groups.

Table 5.6.2-19: Glyphosate technical: Teratological investigation of glyphosate in rats and rabbits ([redacted] 1981): Summary of litter parameters – Prenatal group

Parameter	Glyphosate (mg/kg bw/day)			
	0 (control)	22	103	544
No. of mated females	13	12	15	15
Mean No. of implantations/dam	12.08	12.58	14.67	13.00
Mean No. of dead foetuses/dam	1.77	0.67	1.87	0.67
Foetal loss (%)	14.65	5.30	12.73	5.13
Mean No. of live foetuses/dam	10.31	11.92	12.80	12.33
Mean litter weight (g)	25.46	28.23	28.13	30.53
Mean foetal weight (g)	14.65[1]	5.30[1]	2.07[2]	2.50[2]
Externally abnormal foetuses	0	0	0	0

[1] values as given in the report, but unrealistic for rat foetuses at term, in looking at the table in the report it appears the values for foetal loss (%) were accidently repeated here.
[2] values as given in the report, but untypically low for rat foetuses at term

External, visceral and skeletal examination
No externally abnormal foetuses were noted in any prenatal group. No treatment related skeletal or visceral effects were observed.

Postnatal group
Pup growth during lactation was faster than in the controls. No treatment related micro- or microscopic effects were observed. The lactation index was 97% in both the treated and control group.

III. CONCLUSIONS

No treatment related effects were observed in the dams. Body weight was similar in the treated groups, the body weight gain in the mid- and high-dose groups was slightly lower than in controls throughout the pregnancy. No gross or histopathological effects were observed in the pre- and postnatal groups. No treatment related effects were observed with foetuses or neonates. Based on these results the non-teratogenic level is larger than 544 mg/kg.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The NOAEL for maternal as well as development toxicity was considered to be 544 mg/kg bw/day based on no evidence of maternal or developmental toxicity attributable to glyphosate in either the pre- or postnatal groups.

Assessment and conclusion by RMS:

Report No	401-054
Document No	M-644179-02-1
Guidelines followed in study	Study was performed before adoption of OECD Guideline, but in general accordance with OECD Guideline 414 (1981)
Deviations from current test guideline (OECD 414, 2018)	The following endpoints were not assessed: food consumption, weight and histopathological changes of the thyroid glands of the dams, anogenital distance (AGD) in foetuses, indication of incomplete testicular descent/cryptorchidism in male foetuses, blood samples from dams to assess thyroid hormones (T4, T3 and TSH) were not collected. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	No, not conducted under GLP (GLP was not compulsory at the time the study was performed)
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Pregnant COBS® CD@ rats were used to determine the teratogenic potential of technical glyphosate. Dosage levels of 0, 300, 1000 and 3500 mg/kg bw/day were administered orally by gavage as a single daily dose on days 6 through 19 of gestation at a constant volume of 10 mL/kg. The control group received the vehicle, 0.5 % aqueous Methocel®, on a comparable regimen. Cesarean sections were performed on all surviving females on gestation day 20. Biologically meaningful differences in appearance and behavior were noted in the 3500 mg/kg bw/day dosage group when compared to the control group and included breathing rattles, reduced activity and an increase in soft stool and diarrhoea. Six animals in this dosage group died by gestation day 17. The causes of death could not be determined at necropsy. A reduced gain in mean maternal body weight was noted over the treatment period in the 3500 mg/kg bw/day dosage group, as well as an increase in early resorptions, a slight increase in post-implantation loss and decreases in mean foetal body weight and the mean number of viable foetuses. An increase in the number of foetuses with reduced ossification of the sternebrae was also noted in this dosage group. No signs of maternal or developmental toxicity were noted at 300 or 1000 mg/kg bw/day.

Treatment with glyphosate produced signs of maternal and foetal toxicity in the 3500 mg/kg/day dosage group, as evidenced by maternal deaths, an increase in early resorptions and decreases in mean foetal body weight and the mean number of viable foetuses. Glyphosate did not produce a teratogenic response when administered to rats at a dosage level of 3500 mg/kg bw/day or less.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:	Glyphosate technical	
Description:	White powder	
Lot/Batch #:	XHJ - 64	
Purity:	98.7 %	
Stability of test compound:	Not reported	
Vehicle:	0.5 % aqueous Methocel®	
Test Animals:		
Species:	Rat	
Strain:	Charles River COBS® CD®	
Source:	[redacted]	
Age:	Approx. 14 weeks when mated	
Sex:	Females	
Weight at dosing:	288 - 302 g (mean group values)	
Acclimation period:	At least 10 days	
Diet/Food:	Purina® Rodent Laboratory Chow® 5001, *ad libitum*	
Water:	Tap water, *ad libitum*	
Housing:	Individually in suspended wire mesh cages	
Environmental conditions:	Temperature:	controlled, no values reported
	Humidity:	controlled, no values reported
	Air changes:	not reported
	Light:	controlled, no values reported

B. STUDY DESIGN

In life dates: 1979-04-16 to 1979-05-12

Mating procedure: One female and one male rat of the same strain were placed together for mating. The occurrence of copulation was determined by daily inspection for a copulatory plug or by a vaginal inspection for sperm. The day that mating was detected was designated day 0 of gestation.

Animal assignment: Four test groups were employed in the study. Mated females were consecutively assigned in a block design to a control group and three treatment groups consisting of 25 rats each.

Dose selection rationale: Dose selection rationale was not provided.

Dose preparation and analyses: The appropriate amount of test item was ground with mortar and pestle prior to daily suspension in the vehicle, 0.5 % aqueous Methocel® using a tissue homogenizer. A magnetic stir bar and plate were used to ensure proper suspension during administration. Analyses of dose formulations is not reported.

Dose administration: Glyphosate was administered orally, by gavage, to 25 mated female rats per group at dose levels of 0, 300, 1000 and 3500 mg/kg bw/day from day 6 to 19 of gestation. The dose volume was 10 mL/kg bw. Dose volumes were calculated from individual body weights on gestation day 6.

Maternal observations:
Clinical observations:
Prior to treatment, the females were observed daily for mortality and overt changes in appearance and behavior. The females were observed daily for mortality and clinical signs of toxicity on days 6 through 20 of gestation. Dams not surviving to the scheduled sacrifice were necropsied in an attempt to determine the cause of death.

Body weight: Individual maternal body weights were recorded on gestation days 0, 6, 9, 12, 16 and 20.

Food consumption: Food consumption was not recorded.

Necropsy: On gestation day 20, all surviving females were sacrificed by carbon dioxide inhalation. Immediately following sacrifice, the uterus was excised and weighed and the foetuses removed. The location of viable and nonviable foetuses, early and late resorptions and the number of total implantations and corpora lutea were recorded. The abdominal and thoracic cavities and organs of the dams were examined for grossly evident morphological changes and the carcasses discarded.

Foetal observations: All foetuses were individually weighed and examined for external malformations and variations, including the palate and eyes. Each foetus was externally sexed and individually identified. Approximately one-half of the foetuses were placed in Bouin's fixative for subsequent visceral examination by razor-blade sectioning as described by Wilson. The remaining one-half of the foetuses were fixed in alcohol, macerated in potassium hydroxide and stained with Alizarin Red S by a method similar to that described by Dawson for subsequent skeletal examination.

Statistics: All statistical analyses compared the treatment groups to the control group, with the level of significance at $p<0.05$. The male to female foetal sex distribution and the number of litters with malformations were compared using the Chi-square test criterion with Yates' correction for 2 x 2 contingency tables and/or Fisher's exact probability test as described by Siegel to judge significance of differences. The number of early and late resorptions and post-implantation loss were compared by the Mann-Whitney U-test as described by Siegel and Weil to judge significance of differences. The mean number of viable foetuses, total implantations, corpora lutea and mean foetal body weights were compared

by analysis of variance (one-way classification), Bartlett's test for homogeneity of variances and the appropriate t-test (for equal or unequal variances) as described by Steel and Torrie using Dunnett's multiple comparison tables to judge significance of differences.

II. RESULTS AND DISCUSSION

A. MORTALITY

Six rats in 3500 mg/kg bw/day group died, one each on gestation days 10 and 17 and two each on gestation days 11 and 12.

B. CLINCIAL OBSERVATIONS

There were no biologically meaningful differences in appearance or behaviour attributable to treatment with the test item at 300 and 1000 mg/kg bw/day when compared to the control group. Soft stool, diarrhoea or both were noted at least once during the treatment period (in all but three rats) at 3500 mg/kg bw/day, with diarrhoea occurring primarily either prior to death or during the last days of treatment. Breathing rattles and inactivity were noted only in rats at 3500 mg/kg bw/day and red matter in the region of the nose, mouth, forelimbs or dorsal head was noted prior to death. The inactivity was observed in all rats at 3500 mg/kg bw/day each day, beginning mid-way through the treatment period, approximately l/2 to 6 hours after dosing. Inactivity was not present at subsequent dosing until the last few days of treatment when animals were inactive before and after dosing.

C. BODY WEIGHT

There were no biologically meaningful differences in mean maternal body weight gain at 300 and 1000 mg/kg bw/day when compared to the control group. However, a definite reduced mean maternal body weight gain was noted at 3500 mg/kg bw/day over the treatment period due to a mean maternal body weight loss during the first three days of treatment.

Table 5.6.2-20: Glyphosate technical: Teratology study in rats ([redacted] 1980): Mean body weights (g ± SD) and body weight gain (g)

Parameter	Glyphosate technical (mg/kg bw/day)			
	0 (control)	300	1000	3500

Day 0 - 20	146	133	142	112

* Initial group size of pregnant animals was n=23, further reduced in the course of the study due to 6 mortalities

E. NECROPSY

Stomach haemorrhages were noted in two deceased rats from the 3500 mg/kg group at necropsy, however, a cause of death could not be determined for any of the six deceased dams. At sacrifice on day 20, two incidences of hydronephrosis were found, one each at 1000 and 3500 mg/kg bw/day. One incidence of splenic necrosis and adhesive peritonitis was found at 300 mg/kg bw/day at histopathological examination.

Out of 25 mated females, 22, 20, 21 and 16 had live young at day 20 in the control, and at 300, 1000 and 3500 mg/kg bw/day groups, respectively. There were no biologically meaningful differences in the mean number of viable foetuses, late or early resorptions, post-implantation loss, corpora lutea, the foetal sex distribution or mean foetal body weight at 300 and 1000 mg/kg bw/day when compared to the control group and nonviable foetuses were not present in any group. A statistically significant decrease in the mean number of total implantations and viable foetuses at 300 mg/kg bw/day dosage group was attributed to random occurrence.

At 3500 mg/kg bw/day, there were no late resorptions although a statistically significant increase in the mean number of early resorptions resulted in a slight increase in mean post-implantation loss. A statistically significant decrease in the mean number of total implantations, viable foetuses and mean foetal body weight and a slight decrease in the mean number of corpora lutea was noted in this group. Since ovulation and implantation occurred prior to treatment, the decreases in total implantation and corpora lutea were considered not to be treatment related.

F. FOETUSES

Mean litter size was statistically significantly reduced at 300 and 3500 mg/kg bw/day which was mainly due to an incidentally lower number of corpora lutea and an incidentally higher incidence of pre-implantation loss. As discussed above these differences were considered not treatment related. Mean litter size at 1000 mg/kg bw/day was similar to that of the control group.

At 3500 mg/kg bw/day, mean foetal weights were reduced in comparison with controls with differences from control values attaining statistical significance. At 300 and 1000 mg/kg bw/day mean foetal weights were similar to those of the control group. No differences in foetal sex ratios were noted between test item-treated groups and the control group.

Table 5.6.2-21: Glyphosate technical: Teratology study in rats ([redacted], 1980): Litter data

* Statistically significant difference from control group mean, $p<0.05$
** Statistically significant difference from control group mean, $p<0.01$

Findings in external, visceral and skeletal examination:
There were no malformations observed at 300 and 1000 mg/kg bw/day. At 3500 mg/kg bw/day, the number of litters with malformations was identical to the control group, however, several foetuses with either the anomaly classified as dwarfism or bent tails were found in single litters. As a result, an increase in the number of foetuses with malformations was noted in this group when compared to the control group. These increases were considered genetic in origin as bent tail and dwarfism occurred in several foetuses in a single litter in the historical control data. Developmental and genetic variations at 300 and 1000 mg/kg bw/day were comparable to the control group. An increase in the number of litters and foetuses with unossified sternebrae was noted in the 3500 mg/kg bw/day dosage group and was considered a developmental variation.

Table 5.6.2-22: Glyphosate technical: Teratology study in rats ([redacted], 1980): Summary of foetal malformations and developmental and genetic variations

Observation	Glyphosate technical (mg/kg bw/day)

III. CONCLUSIONS

Treatment with glyphosate produced signs of maternal and foetal toxicity in the 3500 mg/kg bw/day dosage group. Glyphosate did not produce a teratogenic response when administered to pregnant rats at dosage levels of 3500 mg/kg bw/day or less. Accordingly the NOAEL for maternal and embryofoetal toxicity was considered to be 1000 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study from 1980 is considered valid in spite of deviations to the recent OECD guideline (OECD 414, 2018).

The maternal NOAEL was set at 1000 mg/kg bw/day based on mortality, clinical signs and decreased body weight gain at 3500 mg/kg bw/day. Foetal effects were also confined to the top dose level of 3500 mg/kg bw/day. Foetal weights were significantly reduced. The mean number of viable foetuses per litter and the mean foetal weight were decreased. There was a significant increase in early resorptions causing a slight increase in total post-implantation loss.The total number of foetuses with malformations was increased at the highest dose level but the number of affected litters was identical to that in the control groups. Since the incidence and type of malformations were similar to those from historical control data, it was concluded that these findings were not related to treatment. The higher number of foetuses with unossified sternebrae in this dose group was considered an adverse effect of compound administration secondary to maternal toxicity. However, this a developmental variation not a malformation. Thus, the NOAEL for the maternal as well as for foetotoxicity was 1000 mg/kg bw/day in this study.

Assessment and conclusion by RMS:

Rabbit studies

Eight developmental toxicity studies in rabbits discussed in the previous EU evaluations are summarised below in Table 5.6.2-23 nothing where there are differences in study report and previous AIR NOAEL values and LOAEL effects. In addition, preliminary studies with non-pregnant and pregnant animals are discussed (Table 5.6.2-24) as well as other data to better characterize the adverse gastrointestinal effects of gavage administration of glyphosate acid in rabbits.

§ The category describNOes the acceptability/reliability of the study within the AIR 5 submission. This category does not describe hazard classification.

The previous EU Annex I Renewal review concluded that the NOAEL for maternal and developmental effects in rabbits was 50 mg/kg bw/day ([redacted] (1991) (CA 5.6.2/014 and 5.6.2/015), with maternal LOAEL of 150 mg/kg bw/day; [redacted] (1996) (CA 5.6.2/010) maternal and developmental LOAEL of 200 mg/kg bw/day) and that effects on the foetuses were only observed in the presence of marked maternal toxicity. This NOAEL was then used as the basis for the acceptable daily intake (ADI) and acceptable operator exposure level (AOEL) by the BfR and EFSA, and then also for an acute reference dose (ARfD) by EFSA.

Overall the previous EU evaluation determined that glyphosate was not teratogenic in rabbits. Three additional studies have been included in this submission. The results from these studies are consistent with the data that has been previously reviewed, the pattern of maternal toxicity is consistent and the effects on the foetuses were only observed in the presence of maternal toxicity and no teratogenicity was observed.

Rabbits were more sensitive to oral gavage dosing than other species. In rabbits, glyphosate exposure via oral gavage led to clinical signs of toxicity in does consistent with gastro-intestinal disturbances. Clinical signs observed included diarrhoea/soft faeces, reduced faecal output, reduced body weights, reduced food consumption and increased mortality. Table 5.6.2-23 details maternal toxicity observed following glyphosate treatment via oral gavage. These effects are consistent with gastro-intestinal stasis (ileus) likely caused by the mucosal membrane irritation potential of glyphosate acid. Rabbits (caecotrophs) are particularly sensitive to disruption of the gastro-intestinal tract. Stress and other environmental factors can lead to the normal muscular contractions of the stomach and intestines being greatly diminished, which in turn leads to disruption of the normal intestinal/ceacum bacterial flora. It is likely that the bolus administration of low pH glyphosate acid stresses the does as well as leads to the irritation of mucosal membrane of the rabbit gastro-intestinal tract. Consequently the associated stress leads to gastro-intestinal stasis. The gross necropsy signs observed in maternal animals in the studies by [redacted] (1995) (CA 5.6.2/011), [redacted] (1996) (CA 5.6.2/010) and [redacted] (1996) (CA 5.6.2/009), such as hair like boluses in the stomach, fluid filled large intestines and gas distension in the lower gastrointestinal tract are indicative of gastro-intestinal stasis. These findings appear to be relevant to only hindgut fermenters as it is not seen in rats or dogs following administration of an oral bolus dose.

Table 5.6.2-24: Summary of maternal toxicity in glyphosate acid developmental toxicity in rabbits and preliminary studies in pregnant and non-pregnant rabbits

Study Strain (Reference)	Dose level (mg/kg bw/day)	Maternal Mortality #	Diarrhoea/ loose faeces #	Reduced faecal output #	Body weight effect	Necropsy findings	Number of dams with live young or litters at Day 29 #
Preliminary, Japanese White ([redacted], 1995)	1000	6/6	6/6	not recorded	Remarkably decreased		0/6
	300	0/6	1/6	not recorded	Lower than control		5/6
Definitive, Japanese White ([redacted], 1995)	300	1/18	4/17	0/17	Lower than control	Erosion in the stomach, hair bolus in stomach, watery contents in large intestine/caecum	15/18
Preliminary, non-pregnant NZW ([redacted] 1996)	500 (1 day) then 1000 (4 days)	3/3	3/3	not recorded	Severe body weight loss	Relaxed fecal output, reduced food consumption, anus stained with fecal mterial, ptosis and subdued behaviour and mortality	Not reported
	500 (9 days)	0/3	3/3	3/3	Body weight loss	Fecal staining around anus	Not reported
Preliminary, pregnant NZW ([redacted], 1996)	400	2/6	4/6	2/6	Reduced body weight gain		All 4/6 pregnant, 2/6 aborted or bleeding from vagina
	200	0/6	0/6	0/6	Reduced body weight gain		All 4/6 pregnant
NZW ([redacted], 1996)	400	2/18	10/16	2/18	Initial loss and then statistically significant lower body weight gain than control	Fluid filled large intestines, haemorrhage, ulceration and sloughing of the stomach, duodenum congested and	16/18

- Not reported / not applicable

Strong evidence that maternal toxicities noted in rabbit developmental toxicity studies dosed via oral gavage are related to general gastro-intestinal disturbance (to which rabbits are especially sensitive, as noted above), rather than systemic toxicity following repeated exposure, is the complete absence of systemic toxicity noted in three repeated dose dermal toxicity assays up to equivalent systemic exposures in the same species (see Table 5.3.3-1). Reported gross necropsy observations, organ weights, organ pathology, hematology and clinical chemistry in these repeat-dose studies confirm an absence of specific target organ toxicity following repeated exposure in rabbits. An important consideration is that glyphosate is essentially unmetabolised in mammals and therefore systemic doses provide the opportunity to evaluate for specific target organ toxicity following repeated exposure, irrespective of the route of exposure.

[redacted] (1982) (CA 5.3.3/008) noted no effects up to the highest dose tested in a repeated dose rabbit 21–day dermal toxicity study, 5000 mg/kg bw/day (dermal). In order to understand the equivalent systemic glyphosate dose in these rabbits, [redacted] (2012) (CA 5.8.2/014) measured dermal absorption *in vitro* through rabbit skin and determined that the dermal dosing regimen in [redacted] (1982) (CA 5.3.3/008)

resulted in 2.66 % glyphosate acid available as a systemic dose, i.e. 133 mg/kg bw/day. Applying the glyphosate RAR gastrointestinal absorption value of 20% oral bioavailability[22], the systemic dose of 133 mg/kg bw/day resulting from a dermal dose of 5000 mg/kg bw/day, would be equivalent to an oral dose of 665 mg/kg bw/day; significant toxicity would be expected following an oral dose at this level in rabbits. Furthermore, systemic glyphosate is excreted nearly exclusively through the kidneys, with no biliary excretion and therefore, no gastrointestinal exposure in repeat dose dermal toxicity studies.

Clinical signs of gastrointestinal irritation manifesting as diarrhea and loos stools in rabbits dose orally by gavage in these studies resulted in nutritional compromise and mortality. Lagomorphs, hind gut fermenting herbivorous small mammals (including rabbits), practice coprophagy (consume their own faeces) in order to maintain balanced nutrition. This is a widely known fact and is documented in the scientific literature going back over 130 years;

> "L'ingestion des crottes est un phénomène physiologique. Elle aurait pour but de soumettre les aliments à une seconde élaboration digestive et à une nouvelle absorption. **Cet acte est indispensable à l'entretien de la vie des léporidés**" (page 223 conclusions, Morot, 1882)[23].
>
> "Ingestion of droppings is a physiological phenomenon. It would aim to submit food to a second digestion and a new absorption. **This act is essential to the maintenance of life in rabbits and hares**" (English translation page 223 conclusions, Morot, 1882).

Published research over the last century elucidates that the practice of coprophagy is vital to the rabbit accessing the necessary nutrition to thrive and survive. Rabbits produce two types of fecal pellets on a diurnal cycle; hard pellets by day and small soft nutritious pellets by night (Pickard & Stevens, 1972)[24]. Additional opportunity to absorb nutrients is afforded in the practice of rabbits eating the small soft pellets produced at night, by directly removing them from the anus and swallowing them whole. These pellets are high in nitrogen, protein, sulfur and vitamins. The nutritional significance of coprophagy is especially crucial with reduced feed intake, wherein consumption of up to 100% of the soft feces produced may be required to supply essential dietary needs (Sloave & Brand, 1991)[25]. Research from over 60 years ago noted that the soft feces consumed by rabbits are significantly higher in four vitamins than the hard pellets produced at day; levels of niacin and riboflavin at 3 to 4-fold higher, pantothenic acid 6-fold higher and vitamin B12 2 to 3-fold higher in soft feces than hard (Kulwich *et al.*, 1953)[26].

Published results from research conduced over 40 years ago demonstrated that preventing coprophagy in rabbits resulted in a substantial reduction in body weight gain (Stevens, 1977)[27]. These results were of no great surprise, given earlier research showed that preventing coprophagy resulted in decreased digestibility of dry matter, decreased protein digestibility and decreased nitrogen utilisation in the rabbit (Thacker & Brandt, 1955)[28]. Subsequently it was shown that the soft feces contain enzymes which aid in the digestion of proteins (Camara & Prieur, 1984)[29].

The rabbit studies (including maximum tolerated dose, pilot and definitive studies) summarised in the Table 5.6.2-24 note a high incidence of diarrhea and loose stools where maternal mortality is recorded. As a consequence, the essential practice of coprophagy was not possible (soft pellets could not form due to diarrhea), leading to nutritional compromise of these oral gavaged rabbits.

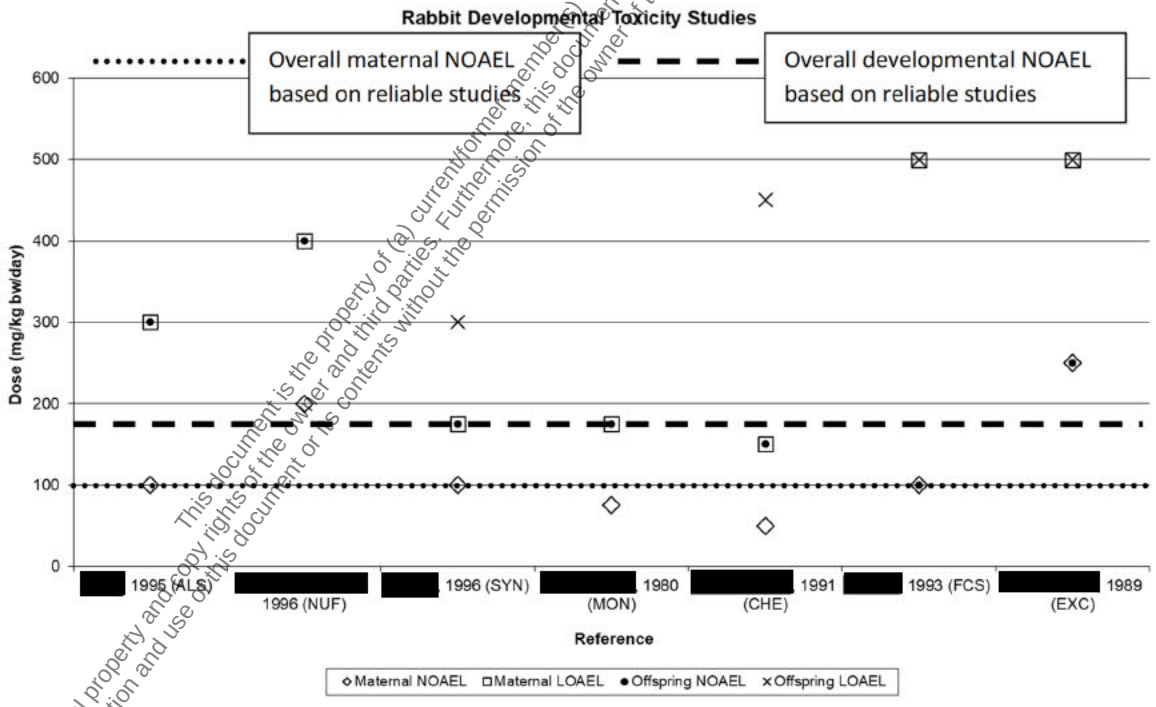
Gastrointestinal irritation manifesting as diarrhea and loose stools in these rabbits dosed orally by gavage, resulted in nutritional compromise and mortality. This hypothesis is consistent with the mortality noted in the latter portion of the developmental toxicity studies, particularly at the high doses. Such severe effects are not observed in the multiple repeat-dose dermal toxicity studies in the same species with higher systemic exposures to glyphosate, where no specific target organ toxicity was identified during gross necropsy or microscopic examinations of organs. This confirms the hypothesis that the maternal effects observed in rabbit developmental toxicity studies are not evidence of systemic toxicity and are not relevant to humans.

The current European ADI for glyphosate is based on a 50 mg/kg bw/day NOAEL in two rabbit studies ([redacted] (1991) (CA 5.6.2/014 and 5.6.2/015); [redacted] (1996) (CA 5.6.2/010)). However, the large glyphosate data set with multiple rabbit developmental toxicity studies clearly demonstrates an overall maternal NOAEL of 100 mg/kg bw/day and offspring NOAEL of 175 mg/kg bw/day (Figure 5.6.2-~~1~~2). However, given the discussion above the rabbit maternal toxicity findings are clearly not relevant to humans for three simple reasons. Firstly, humans are not exposed to bolus doses of glyphosate acid in their diet, and therefore are not subjected to the irritating effects seen in rabbit gastrointestinal tracts. Secondly, the maternal toxicity in rabbit developmental toxicty studies is not due to subchronic or chronic exposures. Thirdly, humans are not coprophagic; we obtain our nutrients through a balanced diet rather than nutrient recycling via the consumption of faeces.

Figure 5.6.2-2: Results and overall maternal and developmental NOAELs of developmental toxicity studies in rabbits



The AOEL is a health-based exposure level to protect workers from systemic toxicity. In the previous Annex 1 Renewal the AOEL was based on the rabbit maternal toxicity endpoint, discussed above, and the GRG believe this endpoint is not appropriate because it was not established based on systemic toxicity. Rather the maternal effects seen at ≥150 mg/kg bw/day (Figure 5.6.2-1) are the consequence of gastrointestinal disturbances following bolus dosing of an acidic material and at higher doses, and the inability to perform coprophagy which over time results in malnutrition.

A recent analysis of acute reference dose (ARfD) setting in Europe (Moxon, 2020)[30], notes there are a number of potentially errantly assigned ARfDs, particularly where the endpoint selection is based on developmental toxicity studies. Moxon (2020) (CA 5.6.2/009) notes three relevant toxicological effects that may be based on a developmental toxicity, as described by the JMPR (2002)[31].

(i) Early effects noted in repeat dose studies: the effects noted at the overall maternal LOAEL for do not appear early in the study.
(ii) Reproductive/developmental effects: the overall offspring LOAEL of 300 mg/kg bw/day (Table 5.6.2-23) and previous RAR offspring LOAEL of 200 mg/kg bw/day ([redacted] (1996) (CA 5.6.2/010) are in the presence of maternal toxicity, and the overall reproductive/developmental NOAEL is 175 mg/kg bw/day. Moxon (2020) points out that such effects in the presence of maternal toxicity are of questionable relevance.
(iii) Direct effects on the gastrointestinal tract, where considered relevant to human exposures: bolus dosing via gavage is not representative of human dietary exposures.

Moxon (2020) also notes that unreliable studies should not be used over and above reliable definitive toxicity studies, and therefore the [redacted] (1993) (CA 5.6.2/012 and CA 5.6.2/013) study, summarised below should be disregarded in this case. In addition, with the lack of human relevance for rabbit gastrointestinal effects which result in the inability of rabbits to perform coprophagy to maintain nutritional balance, the acute reference dose (ARfD) from the previous EFSA conclusion, does not appear to be justified.

1. Information on the study

Data point:	**CA 5.6.2/009**
Report author	[redacted]
Report year	1996
Report title	Glyphosate acid: Developmental toxicity study in the rabbit
Report No	[redacted]/P/5009
Document No	Not reported
Guidelines followed in study	OECD 414 (1981), EEC B.31 (1988),US-EPA 83-3
Deviations from current test guideline (OECD 414, 2018)	Dosed from day of implantation through the period of organogenesis, rather than through to day prior to necropsy
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Glyphosate acid was administered by gavage to three groups of 20 mated New Zealand White rabbits each, at doses of 100, 175 and 300 mg/kg bw/day from gestation day 8-20 (mating = day 1). A further group of 20 animals was exposed to the vehicle (deionised water) to serve as control.

[30] Moxon M Strupp C Aggarwal M Odum J Lewis R Zedet S Mehta J. An analysis of the setting of the acute reference dose (ARfD) for pesticides in Europe. *Regul. Toxicol. Pharmacol.* 113 (2020) 104638.
[31] JMPR, 2002. Further Guidance on Derivation of an Acute RfD, Pesticide Residues in Food – 2002, Report on the JMPR, vol. 178 FAO Plant Production and Protection Paper, pp. 4-8 2002.

Individual clinical observations, body weight and food consumption were recorded during the study. The females were killed on day 30 of gestation, examined macroscopically for external and internal malformation. The uteri were examined number of corpora lutea, implantation number, position and type, foetal weights, foetal sex, external appearance and internal visceral anomalies/abnormalities were recorded. All live foetuses were preserved, processed and subsequently examined for skeletal anomalies with the heads of half the offspring preserved and examined for visceral anomalies.

Administration of 175 or 300 mg/kg bw/day was associated with dose-related maternal toxicity. This toxicity was manifested as signs of diarrhoea, reduction in faecal output as a result of reduced food consumption and a corresponding reduction in body weight. There was no maternal toxicity attributable to the administration of 100 mg/kg bw/day. At the high dose level, when maternal toxicity was seen, a reduction in mean foetal weight and very minor alterations in foetal ossification were evident. There was no effect on the number of foetuses or their survival and there was no evidence of teratogenicity.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate acid
Description:	White solid
Lot/Batch #:	P24
Purity:	95.6 %
Stability of test compound:	The stability of the test substance was confirmed for the study period.
Vehicle:	Deionised water
Test Animals:	
Species:	Rabbit
Strain:	New Zealand White
Source:	[redacted]
Age:	Not reported
Sex:	Females (time-mated)
Weight at dosing:	approximately 3.8 kg
Acclimation period:	At least 4 days
Diet/Food:	Harlan Teklad 9603TRB rabbit diet, *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually in mobile rabbit units
Environmental conditions:	Temperature: 17 ± 2 °C Humidity: 55 ± 15 % Air changes: 25-30/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: 1996-01-01 to 1996-02-09

Animal assignment and treatment:
Eighty time-mated females were supplied. Sexually mature, virgin females were paired with stud males. The day of copulation was designated Day 1 of gestation. The females were delivered to [redacted] at or before Day 3 of gestation and were allocated randomised to treatment groups. Groups of 20 time-mated New Zealand White female rabbits received 0, 100, 175 or 300 mg/kg bw/day test substance by gavage (2 mL/kg bw) from gestation Day 8-20. The dose levels were chosen based on results of a preliminary dose finding.

Dose formulation and analysis
For each dose level an appropriate amount of deionised water was added to a weighed amount of glyphosate acid (adjusted for purity). Each preparation was thoroughly mixed and subdivided into aliquots. Fresh aliquots were used for each day of the study. Two preparations were made per concentration (i.e. 0, 50, 87.5 and 150 mg/mL). The dosing preparations were stored at room temperature. Representative samples of each dosing preparation were analysed prior to being used for dosing to verify the achieved concentration of glyphosate acid in the vehicle. Samples were taken for the determination of homogeneity at 50 and l50 mg glyphosate acid/mL (low and high dose levels).
The chemical stability of glyphosate acid in the vehicle was determined by re-analysis of the lowest and highest concentrations of the dosing preparations after an interval of 40 days.
Dose formulations were shaken prior to dosing, and during dosing as required.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made once daily during the pre- and post-dosing periods and twice daily (before and after dosing) during the dosing period.

Body weight
Individual body weights were recorded on arrival, on Day 4, prior to dosing on days 8 to 20 and on days 23, 26 and 30 of gestation.

Food consumption
Food consumption of females was recorded on days 4-8, days 8-11, days 11-14, days 14-17, days 17-20, days 20-23, days 23-26 and days 26-30 of gestation.

Sacrifice and pathology
All rabbits at scheduled termination on day 30 and any requiring euthanasia during the study were killed by an overdose of 200 mg/mL sodium pentobarbitone solution given as i.v. injection. All animals were subjected to an examination *post mortem*. This involved an external observation and an examination of the thoracic and abdominal viscera. The pregnancy status of each animal was determined. Where there was no clear evidence of implantation, the uterus was removed and stained with ammonium polysulphide to determine whether or not implantation had occurred. For pregnant animals the intact gravid uterus (minus ovaries and trimmed free of connective tissue) was removed and weighed. The ovaries, uterus and contents where then examined. Number of corpora lutea, number and position of implantations, number of live foetuses, foetus weight and early and late intrauterine deaths were determined for each sacrificed doe.

Developmental parameters
After weighing the foetuses were killed with an intracardiac injection of approximately 0.1 mL of 200 mg/mL pentobarbitone sodium solution. An external examination of each foetus was made together with an examination of the oral cavity. All foetuses were then examined internally for visceral abnormalities, sexed, eviscerated and fixed in 70 % industrial methylated spirits. After approximately 24 h the head of each foetus was cut along the fronto-parietal suture line and the brain was examined for macroscopic abnormalities. The carcasses were then returned to 70 % industrial methylated spirits for subsequent processing and staining with Alizarin Red S. The remaining stained foetal skeletons were examined for abnormalities and the degree of ossification was assessed.

Statistics
Data relating to those animals which were non-pregnant and animals that died intercurrently were excluded

from the statistical analysis. Maternal body weight during the dosing and post dosing periods was considered by analysis of covariance on initial (day 8) body weight. Maternal food consumption during the dosing and post dosing periods, the numbers of implantations and live foetuses per female, gravid uterus weight, litter weight, mean foetal weights per litter and mean *manus* and *pes* scores per litter were considered by ANOVA. Maternal performance data, the proportion of foetuses with each individual *manus* and *pes* score, the proportion of foetuses with each defect and the proportion of litters with each defect were considered by Fisher's Exact Test. Pre-implantation loss, post-implantation loss, early intra-uterine deaths, late intra-uterine deaths, male foetuses, major external visceral defects, minor external/visceral defects, external visceral variants, major skeletal defects, minor skeletal defects and skeletal variants were analysed as follows:
1) Percentages were analysed by ANOVA following double arcsine transformations of Freeman and Tukey (1950),
2) the proportion of foetuses and, with the exception of male foetuses, the proportion of litters affected were considered by Fisher' s Exact Test.

All analyses were carried out in SAS (1989). For Fisher's Exact Tests the proportion in each treated group was compared to the control group proportion. Analyses of variance and covariance allowed for the replicate structure of the study design. Least-squares means for each group were calculated using the LSMEAN option in SAS PROC GLM. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squares mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a Student's t-test, based on the error mean square in the analysis.
All statistical tests were two sided.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS

The concentrations of glyphosate acid in the dosing formulations were within 12% of the target concentrations. The homogeneity and stability of the test substance in the dosing formulations was satisfactory.

B. FOOD CONSUMPTION

During the dosing period, does receiving 175 or 300 mg/kg bw/day showed significantly reduced food consumption compared to the controls.

Table 5.6.2-25: Glyphosate acid: Teratology study in the rabbit ([redacted], 1996): Mean food consumption (in g/rabbit/day) during gestation

	Day of gestation	Dose level in mg/kg bw/day			
		0 (Control)	100	175	300
	4 - 8	155	144	139	160
During Dosing	8 - 11	183	171	158*	149**
	11 - 14	172	162	137**	131**
	14 - 17	172	163	123**	98**
	17 - 20	177	168	143*	115**
Post Dosing	20 - 23	185	176	180	172
	23 - 26	158	160	179	179
	26 - 30	137	148	166*	175*

* Significantly different from control at $p<0.05$
** Significantly different from control at $p<0.01$

C. MORTALITY

The incidence of intercurrent deaths was 1, 2, 2 and 2 in the control, 100, 175 and 300 mg/kg/ bw/day groups, respectively.

In the post-dosing period, one doe in the control group showed weight loss, reduced food consumption, signs of diarrhoea, mucus in the faeces, few faeces and staining in the genital area. This animal aborted on day 30. Changes in the stomach and caecum were observed *post mortem*.

In the low dose level group, one doe showed slight loss of body weight and reduced food consumption between days 4 and 8 (i.e. prior to the onset of dosing) and this response continued into the dosing period, until the animal aborted its litter on day 19. Examination *post mortem* noted the presence of a mass in the right inguinal region of the abdominal cavity. A second animal in this group aborted its litter on day 25 having shown weight loss and reduced food consumption from day 14.

At the intermediate dose level, one doe was killed for humane reasons on day 23 having shown loss of body weight and reduced food consumption from day 4 on. By day 23, the animal had become thin and subdued and all uterine implantations were found to be dead. A second animal in this group aborted its litter on day 22 having shown slight weight loss from day 14 and reduced food consumption from day 4. At the high dose level, two animals aborted their litters on days 24 and 23, respectively. Both animals showed a reduction in food consumption from day 11 and body weight loss from day 11/13. A hair-like substance was found in the stomachs of both animals at examination *post mortem*.

D. CLINICAL OBSERVATIONS

In the high dose level group, there was an increased incidence of animals producing few faeces, with signs of diarrhoea or with staining in the genital area, in comparison with the control group. The production of few faeces and signs of diarrhoea were also of increased incidence in does of the intermediate dose group. There were no clinical effects observed in rabbits treated at a dose level of 100 mg/kg bw/day (see table below).

Table 5.6.2-26: Glyphosate acid: Teratology study in the rabbit ([redacted], 1996): Observed clinical signs during the dosing period

Clinical sign	Number of rabbits affected in dose group			
	Control	Low	Intermediate	High
	(0 mg/kg be/day)	(100 mg/kg bw/day)	(175 mg/kg bw/day)	(300 mg/kg bw/day)
Blood on tray	0	2	2	1
Cold	0	0	1	0
Dry sores 1 or more areas	0	1	0	0
Ears torn	0	2	1	1
Eye opaque	0	1	0	0
Few faeces on tray	3	3	9	9
Mucus in faeces	1	0	0	0
No faeces on tray	0	1	2	3
Scabs in 1 or more areas	4	6	3	3
Signs of diarrhoea	4	5	11	19
Staining in genital area	2	2	3	11
Subdued behaviour	0	0	1	0
Thin	0	0	1	2
Urine coloured	0	1	1	0
Wet sores in 1 or more areas	2	0	1	0

E. BODY WEIGHT

Administration of 300 mg/kg bw/day was associated with a reduction in maternal body weight gain. The statistical different observed body weight development at 175 mg/kg bw/day was due to differences in body weights at the begin of the study. All animals except one of the high dose group showed signs of recovery in the post-dosing period. The reduction in food consumption was therefore accompanied by a corresponding reduction in body weight. In the low dose level group, body weight gain was comparable to controls throughout the study period (see table below).

Table 5.6.2-27: Glyphosate acid: Teratology study in the rabbit ([redacted], 1996): Mean body weight development (in g) during gestation

		Dose level in mg/kg bw/day			
		0 (Control)	100	175	300
Animals per group		17	18	17	17
Day of gestation	8	3924	3771	3822	3815
	9	3845	3837	3834	3823
	10	3857	3863	3856	3830
	11	3885	3873	3874	3854
	12	3894	3879	3877	3856
	13	3917	3905	3902	3880
	14	3942	3932	3930	3875

F. PATHOLOGY

Necropsy

There were no macroscopic findings that were considered to be related to the administration of glyphosate acid.

Observations on the ovary and uterus

No treatment related effects were evident in the study.

In the control, low, intermediate and high dose level groups 17, 18, 17, and 17 females, respectively, survived to termination of the main study and were proven to be pregnant. The number and distribution of females that were not pregnant indicate that there were no treatment-related effects on pregnancy rates. Litter size at caesarean necropsy was comparable in all treatment groups.

G. DEVELOPMENTAL PARAMETERS

Number and viability of foetuses

The proportion of foetuses that were male was statistically significantly increased in the intermediate dose level group, in comparison with the control group. In the absence of a dose-related trend, this finding was

considered incidental to the administration of glyphosate acid. There was no adverse effect of glyphosate acid on the number or survival of the foetuses in utero.

Foetal body weights

There was a statistically significant reduction in mean foetal weight in the high dose level group, in comparison with the control group. This difference was considered attributable to two litters for which the mean pup weight was particularly low. These two litters were from females which had the most severe reductions in body weight. Thus, the reduction in foetal weight is considered to be a consequence of maternal welfare rather than a direct effect of glyphosate acid on the foetuses. There was no effect of 100 or 175 mg/kg bw/day on mean foetal weight.

External, visceral and skeletal examination

The number of foetuses with major defects was 3/143 (2/17 litters), 1/147 (1/18 litters), 0/135 (0/17 litters) and 2/144 (2/17 litters) in the control, 100, 175 and 300 mg/kg bw/day groups, respectively. Neither the type nor incidence of major defects provided evidence for an adverse effect of glyphosate acid. The proportion of foetuses with minor external visceral defects was similar for all groups, including the control. There were no significant differences in litter incidences for minor external/visceral defects noted. Consideration of the specific defects provided no evidence for an adverse effect of glyphosate acid (see tables below).

The proportion of foetuses with minor skeletal defects was statistically significantly increased in the 100 and 300 mg/kg bw/day groups, in comparison with the control group, but not in the 175 mg/kg bw/day group. Evaluation of the specific defects noted an increased incidence of foetuses in the high dose level group with partially ossified transverse processes on the 7th cervical vertebra (8 foetuses in 2 litters), unossified transverse processes on the 7th lumbar vertebra (14 foetuses in 4 litters) or partially ossified 6th sternebra (16 foetuses in 7 litters). None of the specific minor defects were statistically significantly increased in the low or intermediate dose level groups. None of the foetuses were found to have an

external/visceral variant.
The proportion of foetuses with skeletal variants was statistically significantly increased in the high dose level group, in comparison with the control group. Evaluation of the specific variants noted a slight, but not statistically significant, increase in the incidence of foetuses in this group with partially ossified odontoids (62 foetuses in 15 litters) or with 27 pre-sacral vertebrae (37 foetuses in 12 litters).
The slightly higher mean *manus* score observed in the high dose level group, in comparison with the control group, was due to a slight reduction in ossification as shown by the increase in incidence of foetuses scoring 4 or 5. A similar response was apparent from the *pes* scores. The slight reduction in ossification was influenced by the low weight foetuses. There were no treatment-related alterations in foetal ossification in the 100 or 175 mg/kg bw/day groups.

Table 5.6.2-29: Glyphosate acid: Teratology study in the rabbit ([redacted], 1996): Summary of the type and incidence of major defects

Major foetal defects	Number of foetuses affected in dose group*			
	Control	Low	Intermediate	High
	(0 mg/kg bw/day)	(100 mg/kg bw/day)	(175 mg/kg bw/day)	(300 mg/kg bw/day)

III. CONCLUSIONS

The oral administration of glyphosate acid to time-mated rabbits by gavage at a maximum dose level of 300 mg/kg bw/day from Gestation Day 8-20 resulted maternal toxicity at 175 and 300 mg/kg bw/day. Administration of 300 mg/kg bw/day was associated with a reduction in mean foetal weight and minor alterations in foetal ossification. There was no effect on the number of foetuses or their survival and there was no evidence for teratogenicity. Therefore the 'No Observed Adverse Effect Level' (NOAEL) was considered to be 100 mg/kg bw/day for maternal toxicity. The NOAEL for developmental toxicity was considered to be 175 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered valid, though treatment duration covered the period from implantation through organogenesis rather than through to the day prior to necropsy, as recommended in the current OECD 414 guideline.

The oral administration of glyphosate acid to time-mated rabbits by gavage at a maximum dose level of 300 mg/kg bw/day from Gestation Day 8-20 resulted in maternal toxicity at 175 and 300 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level that could not be attributed to maternal toxicity.

Therefore the NOAEL was considered to be 100 mg/kg bw/day for maternal toxicity. The NOAEL for developmental toxicity was considered to be 175 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/010**
Report author	[redacted]
Report year	1996
Report title	Glyphosate technical: Oral gavage teratology study in the rabbit
Report No	434/020
Document No	Not reported
Guidelines followed in study	OECD 414 (1981), JMAFF 59 NohSan 4200 (1985), US-EPA 83-3 (1984)
Deviations from current test guideline (OECD 414, 2018)	Dosed from day of implantation through the period of organogenesis, rather than through to day prior to necropsy
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised	Yes

testing facilities	
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

In an initial maximum tolerated repeat dose study, 434/019 Part II, appended to the final report 434/020, three non-pregnant rabbits were dosed at 500 for one day, then stepped up to 1000 mg/kg bw/day for four more days. Severe clinical signs of body weight loss, relaxed fecal output, reduced food consumption, anus stained with fecal amterial, ptosis and subdued behaviour and mortality were noted; one animal was found dead and the remaining two terminated in extremis. Then a repeat dose tolerability study three non-pregnant rabbits dosed daily for nine days at 500 mg/kg bw/day. All animals displayed significant body weight loss and reduced food consumption. Therefore the dose of 500 mg/kg bw/day was assumed too high for the preliminary dose range finding study.

In the preliminary dose rangex inding study, 434/019 Part I, appended to the final report 434/020, groups of six pregnant does were dosed with 0, 50, 200 or 400 mg/kg bw/day glyphosate. In high dose animals clinical observations included reduced body weight gain, reduced food consumption, 4/6 presented loose stools and 2/6 were terminated in extremis. Similar but less severe effects were noted at 200 mg/kg bw/day and no maternal effects at 50 mg/kg bw/day. No treatment effects on uterine or foetal parameters examined were noted across all doses.

In the definitive study, glyphosate technical was administered by gavage to three groups of 18 mated New Zealand White rabbits each, at doses of 50, 200 and 400 mg/kg bw/day from gestation day 7-19 (mating = day 0). A further group of 18 animals was exposed to the vehicle to serve as control.
Individual clinical observations, body weight and food consumption were recorded during the study. The females were killed on day 29 of gestation, examined macroscopically for external and internal malformation. The uteri were examined. The number of corpora lutea, implantation number, position and type, foetal weights, external appearance and internal visceral anomalies/abnormalities were recorded. All live foetuses were preserved, processed and subsequently examined for skeletal anomalies with the heads of half the offspring preserved and examined for visceral anomalies.

At the high dose level there was evidence of treatment-related effects resulting in one treatment-related death. Clinical signs of toxicity, particularly scours, reduced faecal output and diarrhoea, reduced body weight gain and reduced food consumption were seen. At the intermediate dose level similar, but less severe, effects were seen on body weight gain. At the low dose level, no treatment related effects were observed. Thus, the only dose-responsive clinical observation was gastrointestinal output (reduced fecal output or loose stools/diarrhoea). Animal deaths were 1, 0, 1 and 2 across increasing dose group; deaths in the control and mid-dose group were attributable to dosing technical errors, but at least one of the high dose deaths was considered treatment-related. There were no treatment-related effects on the uterine or foetal parameters examined in any dose group.

The oral administration of glyphosate technical to time-mated rabbits by gavage from gestation day 7-19 resulted maternal toxicity at 200 and 400 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level.

a) MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White powder

Lot/Batch #:	H95D161A
Purity:	95.3 %
Stability of test compound:	The dose formulation was stable for at least 1 h.
Vehicle:	1% carboxymethyl cellulose
Test Animals:	
Species:	Rabbit
Strain:	New Zealand White
Source:	[redacted]
Age:	17 - 19 weeks
Sex:	Females (time-mated)
Weight at dosing:	2.7 - 4.1 kg
Acclimation period:	At least 4 days
Diet/Food:	SQC Standard Rabbit Diet (SDS Ltd., Witham, Essex, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually in stainless steel cages with grid floor
Environmental conditions:	Temperature: 20 ± 3 °C Humidity: 50 ± 20 % Air changes: 15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: 1995-10-13 - 1995-12-12

Animal assignment and treatment in the preliminary study:
Twenty-four time-mated females were supplied. Sexually mature, virgin females were paired with stud males. The day of copulation was designated ay 0 of gestation. The females were delivered to [redacted] at or before ay 3 of gestation and were allocated randomised to treatment groups. Groups of 6 mated New Zealand white female rabbits received 0, 50, 200 or 400 mg/kg bw/day test substance in 1 % carboxymethyl cellulose by gavage (5 mL/kg bw) from gestation day 7-19. The dose levels were chosen based on results of a preliminary dose finding study with 6 female nulliparous rabbits, where administration of 500 or 1000 mg/kg bw resulted in toxicity signs (scours, fluid filled caecum, stomach ulceration, body weight loss, reduced food consumption). Based on these findings dose levels of ≥ 500 mg/kg bw were considered to be too high for a prolonged study.

Animal assignment and treatment in the main study:
Seventy-two time-mated females were supplied as described for the preliminary study (see above). Groups of 18 mated New Zealand white female rabbits received 0, 50, 200 or 400 mg/kg bw/day test substance in 1% carboxymethyl cellulose by gavage (5 mL/kg bw) from gestation day 7-19.

Dose formulation and analysis
For each dose level, the test material was suspended daily in 1 % carboxymethyl cellulose by weighing the required amount into a glass jar and adding vehicle to make the appropriate final volume. Homogeneity was assured by mixing the formulation with a homogeniser. The concentration, stability and homogeneity of the test material were analysed. The formulation was stable for at least 1 h.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made twice daily (before and after dosing) during the dosing period.

Body weight
Individual body weights were recorded on day 3, 7, 10, 13, 16, 19, 22, 25 and 29 of gestation.

Food consumption
Food consumption of females was recorded on days 3 to 7, days 7 to 10, days 10-13, days 13-16, days 16-19, days 19-22, days 22-25 and days 25-29 of gestation.

Sacrifice and pathology
Females were euthanatised by an i.v. injection of an overdose of sodium pentobarbitone into the auricular vein on day 29 of gestation, examined for macroscopic abnormalities and subjected to caesarean sectioning. The ovaries and uteri were removed, weighed and then examined for the number of corpora lutea and for the number and position of implants and dead or live foetuses. Resorptions and foetal deaths were classified into implantation sites, placental remnants, and macerated foetuses according to the difference in developmental stage at which deaths had occurred. Foetal sex, external and internal foetal appearance and foetal weight was determined. After examination of the ovaries and conceptuses, each female was necropsied.

Developmental parameters
The foetuses were killed by intrathoracic injection of sodium pentobarbitone. All foetuses were dissected and examined for visceral abnormalities macroscopically. The heads of alternate foetuses were removed and identified using an indelible marker and placed in Bouin‘s fixative. After a minimum of 14 days, the heads were transferred to 90 % industrial methylated spirits (IMS) in distilled water and examined for visceral anomalies under a low power binocular microscope (Van Julsingha and Bennett 1977). All foetuses were identified using colour coded wires and placed in 70 % IMS in distilled water. The foetuses were eviscerated, processed and the skeletons stained with alizarin red (Dawson 1926). The foetuses were examined for skeletal development and anomalies.

Statistics in the main study
Female body weight change (relative to day 7 of gestation) and food consumption were analysed statistically by one-way analysis of variance with the Bonferroni multiple comparison test followed by pair wise analysis of control values against treated group values using Students ‘t‘ test where appropriate. All foetal parameters, skeletal development, group incidence of specific visceral and skeletal anomalies were analysed statistically by Kruskall-Wallis non parametric analysis of variance followed by pair wise analysis of control values against treated values using the Mann-Whitney U - test where appropriate.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The test substance was detected at the levels of 81-102 % of the target concentrations in each dosing solution.

B. FOOD CONSUMPTION
In the preliminary study, significantly reduced food consumption was observed while administering in the high dose level of 400 mg/kg/day (days 7 to19 of gestation). This observation was confirmed in the main study. At the high dose level, there was a reduction in food consumption during the dosing period compared to controls (days 10 to 13, $p<0.05$; days 13 to 19, $p<0.01$). No other significant changes were observed in the remaining groups during the main study.

C. MORTALITY

In the preliminary study, two does were killed *in extremis* in the high dose group, one had aborted foetuses and the other was bleeding from the vagina. No mortalities occurred at any dose up to 400 mg/kg/day in the preliminary study.

In the main study, two rabbits were found dead or moribund at the high dose level. One female was found dead prior to dosing on day 19 of treatment. One female was killed *in extremis* on day 20 of treatment. Clinical observations noted at this time included hunched posture, lethargy, ptosis, hypothermia and blood on the litter tray. At the intermediate dose level, one female was found dead after dosing on Day 16 of treatment. Necropsy findings of reddened lungs, a fluid filled thorax and test material in thoracic cavity are consistent with mal-dosing. At the low dose level, no mortalities occurred. One female was found dead two minutes after dosing in the control group. Necropsy findings of blood in thorax, inflated appearance of lungs and a large area of congestion on the right caudal lobe are consistent with mal-dosing.

D. CLINICAL OBSERVATIONS

In both the preliminary and the main study, the clinical signs were in general the same. There was a toxicologically significant increase in the incidence of clinical observations, particularly scours, reduced faecal output and diarrhoea at the high dose level (400 mg/kg bw/day). Observations of lethargy, ptosis, hunched posture, hypothermia and blood on tray were noted for one animal of the main study killed *in extremis*.
At 200 mg/kg bw/day, vaginal bleeding and blood on tray were noted for one animal of the main study. Scours were also noted in animals at 200 and 50 mg/kg bw/day as well as in the control group, but the incidence and duration were not as severe as at the high dose level (see table below). No other treatment-related observations were evident.
Thus, for the findings observed at doses below 400 mg/kg bw/day, a clear dose-response could not be established.

Table 5.6.2-33: Glyphosate technical: Teratology study in the rabbit ([redacted], 1996): Observed clinical signs during the dosing period

Clinical sign	Number of rabbits affected in dose group#			
	Control (0 mg/kg bw/day)	Low (50 mg/kg bw/day)	Intermediate (200 mg/kg bw/day)	High (400 mg/kg bw/day)
Scours	5/14 (4)	10/18 (0)	7/16 (2)	16/16 (2)
Reduced faecal output	1/14 (4)	1/18 (0)	2/16 (2)	6/16 (2)
Diarrhoea	0/14 (4)	1/18 (0)	0/16 (2)	10/16 (2)
Diuresis	0/14 (4)	0/18 (0)	1/16 (2)	0/16 (2)
Blood on tray	0/14 (4)	0/18 (0)	1/16 (2)	1/16 (2)

x/y: number affected / total number of animals in group
Figures in parentheses represent the number of animals having no grossly observable conceptus.

E. BODY WEIGHT

In the preliminary, study a toxicologically significant decrease in body weight gain from Day 13 to 19 *post*

coitum was evident at the high and intermediate dose levels.
Likewise a reduction in group mean body weight gain from Days 9 to 29 *post coitum* was observed in the high dose level group during the main study. The difference in group mean body weight change compared to controls was statistically significant (P<0.05 to 0.01) from Days 13 to 29 *post coitum.* Also in the intermediate dose level group a slight reduction (although not statistically significant) in group mean body weight gain from Day 9 to Day 29 *post coitum* was noted. In the low dose level group body weight gain was comparable to controls throughout the study period (see table below).

Table 5.6.2-34: Glyphosate technical: Teratology study in the rabbit ([redacted], 1996): Mean body weight gain during gestation

Dose level (mg/kg bw)	No. of animals	Body weight change (g) at Day (relative to Day 7)						
		10	13	16	19	22	25	29
0 (Control)	14	29	95	202	260	314	375	409

* Significantly different from control at p<0.05.
** Significantly different from control at p<0.01.

F. PATHOLOGY

Necropsy

The macroscopic necropsy findings of the two does of the high-level dose group that died or were killed *in extremis* included fluid filled large intestines, haemorrhage, ulceration and sloughing of the stomach, duodenum congested and colon, rectum and appendix gas distended. These findings indicate that the test material may affect the gastrointestinal tract. The animal killed *in extremis* at this level also had both uterine horns containing blood and dead foetuses in the uterus. This may be a result of maternal toxicity. All other necropsy findings were not treatment-related.

Observations on the ovary and uterus

No treatment related effects were evident in both the preliminary and the main study.

In the control, low, intermediate and high dose level groups 14, 18, 15, and 15 females, respectively, survived to termination of the main study and were proven to be pregnant. The number and distribution of females that were not pregnant indicate that there were no treatment-related effects on pregnancy rates. Litter size at caesarean necropsy was comparable in all treatment groups.

G. DEVELOPMENTAL PARAMETERS

Number and viability of foetuses

The litter size at caesarean section was comparable in all treatment groups. In the high dose level group, there were slight, but not statistically significant, increases in late foetal deaths and post implantation loss, mainly due to one animal that had nine late deaths, resulting in a post implantation loss of 69.2 %. This was therefore considered not to be a treatment-related effect. At 200 mg/kg bw/day, there were statistically significant increases (p<0.05) in total foetal deaths and post implantation loss. These increases were caused by a slight, but not statistically significant, rise in early foetal deaths. At this dose level, there was no rise in late foetal deaths, as seen at the high level. Since there is no dose response observed, early foetal deaths, late foetal deaths, and total foetal deaths (the sum of early plus late foetal deaths), increases in total foetal deaths and post-implantation loss at 200 mg/kg bw/day were considered not to be treatment-related.

Table 5.6.2-35: Glyphosate technical: Teratology study in the rabbit ([redacted], 1996): Intergroup comparison of litter data

Observation		Glyphosate acid (mg/kg bw/day)

Sex Ratio		0.56	0.51	0.54	0.51

* Significantly different from control at $p < 0.05$.

Foetal body weights

No statistically significant differences were noted in the mean foetal body weights between the control group and the treated groups. Mean total litter weights were comparable in all treatment groups.

External, visceral and skeletal examination

At the high dose level, there was one litter with one foetus with major malformations. This foetus was found to have spina bifida and clubbed and malrotated hind limbs. At the intermediate dose level, two foetuses of two different litters had major malformations. One foetus had retinal infolding and a haemorrhage in the retinal layer, the other acephaly, small kinked tail, bilateral forelimb flexure, interrupted aorta and an intraventricular septal defect. At skeletal examination, this foetus was found to have multiple rib and vertebral column abnormalities. At the low dose level, three foetuses of two different litters had major abnormalities. In one litter, one foetus had forked ribs with a displaced vertebral centrum. In another litter, one foetus had a small eye with retinal infolding and aphakia. A second foetus from this litter had nostrils close together, and a thin nasal septum not attached at posterior pole near the front of the nasal passages. In the control group, there were two foetuses from two different litters with major abnormalities. One foetus had gastroschisis and the other foetus had an extra vertebral arch resulting in scoliosis.

These findings were considered to be within the range of normal variation for this species. There were no treatment-related effects on the degree of skeletal development.

Table 5.6.2-36: Glyphosate technical: Teratology study in the rabbit ([redacted], 1996): Incidence of foetal malformations and variations in rabbits treated with glyphosate acid

Foetal findings	Dose level (mg/kg bw/day)			
	0	50	200	400

III. CONCLUSIONS

The oral administration of glyphosate technical to pregnant rabbits by gavage from gestation day 7-19 resulted maternal toxicity at 200 and 400 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level. Therefore the 'No Observed Adverse Effect Level' (NOAEL) was considered to be 50 mg/kg bw/day for maternal toxicity. The NOAEL for developmental toxicity was considered to be 400 mg/kg bw/day. It was considered that the test material had no teratogenic potential at dose levels up to 400 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered valid, though treatment duration covered the period from implantation through organogenesis rather than through to the day prior to necropsy, as recommended in the current OECD 414 guideline.

The oral administration of glyphosate technical to pregnant rabbits by gavage from gestation Day 7-19 resulted maternal toxicity at 200 and 400 mg/kg bw/day. Therefore the 'No Observed Adverse Effect Level' (NOAEL) was considered to be 50 mg/kg bw/day for maternal toxicity. There were no treatment-related effects on pregnancy or foetuses at any dose level. The NOAEL for developmental toxicity was considered to be 400 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/011**
Report author	[redacted]
Report year	1995
Report title	HR-001: A Teratogenicity Study in Rabbits
Report No	[redacted] 94-0153
Document No	M-301383-01-1

Guidelines followed in study	OECD 414 (1981), JMAFF 59 NohSan 4200 (1985), US-EPA 83-3 (1984)
Deviations from current test guideline (OECD 414, 2018)	Dosed from day of implantation through the period of organogenesis, rather than through to day prior to necropsy
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

In the preliminary study, [redacted] 94-0140, appended to the final report [redacted] 94-0153, groups of six pregnant does were dosed with 0, 30, 100, 300 or 1000 mg/kg bw/day glyphosate. All high dose animals presented loose stools and died. All animals at 300 mg/kg bw/day survived, one animal presented loose stools, subsequently aborted and was found dead.

In the definitive study, glyphosate was administered by gavage to three groups of 18 artificially inseminated Japanese White rabbits each, at doses of 10, 100 and 300 mg/kg bw/day from gestation day 6-18 (artificial insemination = day 1). A further group of 18 animals was exposed to the vehicle to serve as control.

No adverse effects related to test substance treatment were observed in any animals of the low and mid dose group. In the high dose group, defecation of loose stool and subsequent abortion or premature delivery was considered to be related to test substance treatment with regard to the results of the preliminary study.

Mean maternal body weights and body weight gains on days 16-24 of gestation in the high dose group decreased slightly although the differences from controls were not statistically significant.

Examinations at caesarean sectioning demonstrated no significant differences in the gravid uterine weights and the numbers of corpora lutea and implants between the control and the treated groups. The mean number of live foetuses, mean percent incidences of resorptions and foetal deaths, foetal sex ratios, mean foetal body weights, and mean placental weights in the treated groups were comparable to those in the control group.

Teratological examinations demonstrated no test substance-related external, visceral and skeletal abnormalities in any foetuses in any treated groups.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical, Code: HR-001
Description:	White crystal
Lot/Batch #:	T-941209
Purity:	97.56 %
Stability of test compound:	Not reported
Vehicle:	Purified water with 0.5% carboxymethylcellulose

Test Animals:

Species:	Rabbit
Strain:	Japanese White rabbits Kbl:JW, SPF
Source:	[redacted]
Age:	18 weeks (females)
Sex:	Females (males were used for mating only)
Weight at dosing:	3.32 - 4.08 kg
Acclimation period:	10 days
Diet/Food:	GC4 (Oriental Yeast Co., Ltd.), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually in aluminium cages with wire-mesh floors.
Environmental conditions:	Temperature: 22 ± 2 °C Humidity: 55 ± 10 % Air changes: 15/hour 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: 1995-03-31 to 1995-06-09

Animal assignment and treatment:
In a teratogenicity study groups of 18 Japanese White female rabbits received doses of 0, 10, 100 and 300 mg/kg bw/day test substance in carboxymethylcellulose by gavage from Gestation day 6-18 after artificial insemination performed on 12 or 16 females each day for 5 consecutive days. The dose levels were chosen based on results of a preliminary teratogenicity study.

Diet preparation and analyses
For each dose level, dosing solutions were prepared two times during the study by suspending the test substance in purified water with the aid of 0.5 % sodium carboxymethylcellulose. For each dose level dosing solutions were analysed for concentration of the test substance before use.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made once daily during the pre- and post-dosing periods and twice daily (before and after dosing) during the dosing period.

Body weight
Individual body weights were recorded on day 0, 6-18, 24 and 27 of gestation. Body weight gains were calculated by subtracting the body weight value on Day 0 of gestation from each value determined on days 6 through 27 of gestation. Adjusted weights were also calculated by subtracting the gravid uterine weight from the body weight on day 27 of gestation.

Food consumption
Food consumption of females was determined on alternate days from day 0 to day 26 of gestation and on days 26 to 27 of gestation. In each interval, daily food consumption (g/rabbit/day) was calculated for each female by dividing values of total food consumption by the number of days.

Sacrifice and pathology
Females were euthanatised by an injection of an overdose of a pentobarbital sodium solution into the

auricular vein on day 27 of gestation and subjected to caesarean sectioning.
The ovaries and uteri were removed, weighed and then examined for the number of corpora lutea and for the number and position of implants and dead or live foetuses. Resorptions and foetal deaths were classified into implantation sites, placental remnants, and macerated foetuses according to the difference in developmental stage at which deaths had occurred. When uterine implants were not grossly apparent, the uteri were stained with 10 % ammonium sulfide solution to detect very early resorptions. After examination of the ovaries and conceptuses, each female was necropsied.

Developmental parameters
Live foetuses and their placentas were individually weighed. Live foetuses were uniquely identified by litters. Then they were euthanatised by an intraperitoneal injection of a pentobarbital sodium solution and examined for external abnormalities. The eyes were examined for alterations after removing the palpebral skin. The sex of the foetuses was determined by observation of the gonads.
After these examinations, each foetus was examined for visceral abnormalities. Then the thoracic and abdominal organs were removed and preserved in 10 % neutral- buffered formalin along with the ovaries and placentas. The remaining skeletons were fixed in 70 % isopropanol, stained with alizarin red S and cleared in 70 % glycerin for examination of skeletal abnormalities. After examination, skeletal specimens were stored.

Statistics
The following statistical tests were used to estimate significance of differences between the control group and the treated groups. The data on body weights, adjusted body weights, body weight gains, and food consumption of maternal rabbits, numbers of corpora lutea, implants, and live foetuses, and weights of gravid uteri, foetuses and placentas were evaluated as follows: Equality of variances was first evaluated by Bartlett's test. When group variances were homogeneous, a parametric analysis of variance in one-way classifications was used to determine if any statistical differences exist among groups. If the analysis of variance was significant, Dunnett's t-test or Scheffe's multiple comparison test was performed to detect any statistically significant differences between the treated groups and their corresponding controls. When Bartlett's test indicated that the variances were not homogeneous, Kruskal-Wallis test was used for detecting any statistical differences among groups and if significant, Dunnett-type mean rank test or Scheffé-type mean rank test was performed to detect statistical differences between the treated groups and their corresponding controls. Fisher's exact probability test was used for the data on the incidences of clinical and gross pathological findings in maternal rabbits, incidences of maternal rabbits having foetuses with malformations and variations, incidences of foetal malformations and variations, and foetal sex ratio, and Mann-Whitney's U-test for the data on the percent incidences of resorptions and foetal deaths.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The test substance was detected at levels of 95-105 % of the target concentrations in each dosing solution. Analyses for homogeneity indicated that the dose preparations were homogeneous. The test substance was stable in the 0.5 % carboxymethylcellulose solution for at least 14 days after preparation.

B. FOOD CONSUMPTION
Mean food consumption in the treated groups was comparable to that in the control group throughout the study period.

C. MORTALITY
One rabbit in the high dose group died on day 20 of gestation without showing any clinical signs. Females with resorptions only had no grossly observable conceptus but had implantation sites in the uteri. These

animals were excluded form the statistical evaluation.

Table 5.6.2-37: Glyphosate technical: Teratology study in the rabbit ([redacted], 1995): Survival and pregnancy status in maternal rabbits

Dose level (mg/kg bw/day)	No. of females mated	No. of females pregnant	No. of females died or killed	No. of females aborted	No. of females survived	No. of females with resorptions only	No. of females with live foetuses
0	18	18	0	0	18	0	18
10	18	18	0	2	16	1	15
100	18	18	0	0	18	2	16
300	18	18	1	2	15	1	14

D. CLINICAL OBSERVATIONS

During the treatment period one animal each showed hair loss (forelimb) and scab on the auricle, respectively in low and mid dose group, respectively (see table below). In the high dose group four animals showed loose stool and two showed soiled fur in the perianal region that was considered to be an alteration caused by defecation of loose stool. The incidence of loose stool was significantly high when compared with the control.

During the post-dosing period, two and one animal in the control group showed loose stool and red material on the tray, respectively. In the low dose group, hair loss (forelimb) was found in one animal and loose stool in another. Besides these findings, one dam aborted on day 20 of gestation, and another one prematurely delivered on day 27 of gestation. In the mid dose group only one animal showed hair loss in the lower abdominal region. In the high dose group, two animals out of four, that had shown loose stool during the dosing period, still showed this alteration, and one animal out of these two aborted on day 26 of gestation. Although loose stool disappeared from the two other dams, the first prematurely delivered on day 27 of gestation and the second had hair loss (dorsal region).

Considering the results of the preliminary study, defecation of loose stool and subsequent abortion or premature delivery observed in the highest dose group were considered to be related to test substance treatment.

Table 5.6.2-38: Glyphosate technical: Teratology study in the rabbit ([redacted], 1995): Observed clinical signs during the dosing period

Clinical sign	Number of rabbits affected in dose group[#]			
	Control (0 mg/kg bw/day)	Low (10 mg/kg bw/day)	Mid (100 mg/kg bw/day)	High (300 mg/kg bw/day)
No abnormalities detected	18/18 (0)	16/17 (1)	15/16 (2)	13/17 (0)
Hair loss	0/18 (0)	1/17 (0)	0/16 (0)	0/17 (0)

Soiled fur in the perianal region	0/18 (0)	0/17 (0)	0/16 (0)	2/17 (0)
Loose stool	0/18 (0)	0/17 (0)	0/16 (0)	4/17 (1)*

[#] x/y: number affected / total number of animals in group

* Significantly different from control at $p<0.05$.

Figures in parentheses represent the number of animals having no grossly observable conceptus. These animals were excluded from statistical evaluation.

E. BODY WEIGHT

Mean body weights of animals in the low and mid dose group were comparable to those in the control group. In the high dose group, although differences from controls were not statistically significant, the mean values on days 15-24 of gestation were somewhat lower than those in the control group.

Table 5.6.2-39: Glyphosate technical: Teratology study in the rabbit ([redacted], 1995): Body weight gain (g) during gestation

F. PATHOLOGY

Necropsy

Necropsy of maternal animals aborted, prematurely delivered or found dead on the study noted no abnormalities in the rabbits in the low dose group. In the high dose group, the aborted rabbit had yellow-coloured adipose tissue, a hair bolus in the stomach, watery contents in the large intestine and accentuated lobular pattern in the liver. The prematurely delivered rabbit in the high dose group had soiled fur in the perianal region, erosion in the stomach, a hair bolus in the stomach, and watery contents in the caecum. In the dead rabbit, pale liver and ascites (red) in the abdominal cavity were found; however, the cause of death was not known.

Gross pathological findings observed in animals which survived to termination of the study were: hair loss in the lower abdominal or dorsal region in one animal in each of the mid and high dose groups; hair bolus in the stomach in one animal each of the control and low dose groups. The occurrence of these gross pathological findings was low, and considered to be unrelated to test substance treatment.

Observations on the ovary and uterus

In the control, low, mid and high dose groups, 18, 16, 18, and 15 females, respectively, survived to termination of the study and were proven to be pregnant. However, one, two and one females in the low, mid and high dose group, respectively, had no grossly observable conceptus while implantation sites were detected by uterine staining with a 10 % ammonium sulfide solution, indicating very early resorptions; all data from these females were excluded from subsequent calculations.

Examinations of uterine contents demonstrated no abnormalities in all groups including the control. Mean gravid uterine weights and mean numbers of corpora lutea and implants were comparable between the control and the treated groups.

G. DEVELOPMENTAL PARAMETERS

Number and viability of foetuses

No statistically significant differences were noted in the mean number of live foetuses and mean percent incidences of resorptions and foetal deaths between the control group and the treated groups.

Sex ratio, foetal body weights and placental weights

No statistically significant differences were noted in the sex ratios, mean foetal body weights, mean placental weights, mean number of live foetuses, and mean percent incidences of resorptions and foetal deaths between the control group and the treated groups.

External, visceral and skeletal examination

No statistically significant differences were noted in the incidences of maternal animals having foetuses with external, visceral and/or skeletal malformations in the low and mid dose groups when compared with the controls. In the high dose group, the number of litters with malformations was significantly higher than that in the control group (see table below). This increased malformation rate was due to an increase in skeletal malformations, as no external or visceral malformations were noted in foetuses from the high dose group. This was considered to be a sporadic alteration rather than the test substance treatment-related alteration because the types of skeletal malformations observed were inconsistent. Further, a dose-response in the number of foetuses showing skeletal malformations was not evident across dose groups.

With regard to variations, the incidence of total no. of litters with skeletal variations in the 100 mg/kg bw/day group was significantly higher than that in the control group (see table below). This high value was due to a significantly high incidence (87.5 % of litters, 27.3 % of the foetuses) of lumbar ribs in this dose group when compared with the control (72.2 % of litters, 16.4 % of foetuses). The total litter incidence for skeletal variations in the 100 mg/kg bw/day group was 100 %. However, the increased incidence of lumbar ribs in the 100 mg/kg bw/day group was considered to be a sporadic alteration because the value was within the historical control range (8.1-35.0 % of examined foetuses), and because no such increase was observed in the 300 mg/kg bw/day group (13.4 %).

III. CONCLUSIONS

Study conclusion:
The oral administration of glyphosate to artificially inseminated rabbits by gavage from gestation day 6-18 resulted in treatment-related changes at 300 mg/kg bw/day. Therefore the 'No Observed Adverse Effect Level' (NOAEL) was considered to be 100 mg/kg bw/day for maternal toxicity. No developmental toxic effects were observed. The NOAEL for offspring was considered to be 300 mg/kg bw/day.

1. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable, though treatment duration covered the period from implantation through organogenesis rather than through to the day prior to necropsy, as recommended in the current OECD 414 guideline. The NOAEL for maternal and developmental effects was 100 mg/kg bw/day and 300 mg/kg bw/day, respectively.

Assessment and conclusion by RMS:

2. Full summary

This developmental toxicity study in rabbits is not clearly or accurately documented and does not provide appropriate interpretation of the study findings. Groups of presumed mated female New Zealand White rabbits were administered once daily by gavage, glyphosate (batch No.: 60, purity 96.8 %) in 0.5 % carboxymethylcellulose (dose volume 2 mL/kg bw) at dose levels of 0 (vehicle control), 20, 100 or 500 mg/kg bw/day from day 6 to day 18 of pregnancy (mating = day 0). Dose volumes were calculated for individual animals from day 6 and adjusted according to body weight daily. The day of mating was considered as day 0. Dose levels were based on the findings of preliminary studies. All animals were observed twice daily for onset and duration of signs of toxicity and for mortality. All animals in the experiment that died, were killed moribund or killed at termination on day 28 were subjected to *post mortem* gross pathological examination. Individual body weights of dams were recorded on days 0, daily from days 6 – 18 and on day 28 of gestation.

The ovaries and uteri were examined to determine the number of corpora lutea, implantations, the number of dead/abnormal/live foetuses, the number and distribution of embryonic and /foetal resorptions. Foetuses were examined for individual foetal weight and foetal abnormalities, sex and visceral organ malformations by foetal necropsy/modified Wilson's technique. The eviscerated and skinned foetuses were stained with Alizarin Rad-S for skeletal evaluation.

There were 4/16 and 8/15 mortalities at dose levels of 100 and 500 mg/kg bw/day, respectively. The deaths at 500 mg/kg bw/day were accompanied by clinical signs, including the increased incidence of soft liquid/diarrhoea or mucoid faeces, reduction in feed consumption and reduction in body weight gain during the treatment period. However, clinical signs were not evident for the 100 mg/kg bw/day dose group and only one incidence of soft faeces was recorded at 100 mg/kg bw/day. Further, a number of lung and tracheal findings in the dams at gross necropsy indicated possible gavage errors to which the deaths at this dose may be attributed.

Glyphosate technical was considered not to be teratogenic in this developmental toxicity study in rabbits. The incidence of one visceral effect, dilated heart, was increased at the highest test dose and was present at lower dose levels, but there were too few foetuses present in the high dose group to corroborate a dose-response relationship. Further, foetal findings at the highest test dose were observed in the presence of extensive maternal toxicity. Mortality and clinical signs of toxicity at 500 mg/kg bw/day included reduced feed consumption and soft faeces and reduced body weight gain during the dosing period one incidence of complete resorptions.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	Odourless white crystals
Lot/Batch #:	60
Purity:	96.8 %
Stability of test compound:	Stable over 2 years at ambient temperature
Vehicle:	0.5 % w/v carboxymethylcellulose
Test Animals:	
Species:	Rabbit
Strain:	Female New Zealand White
Source:	[redacted]
Age:	Approximately 6 months and above (at the start of study)
Sex:	Females (males were used for mating only)
Weight at dosing:	Females: >2500 g (group mean values)
Acclimation period:	At least 10 days.
Diet/Food:	Pelleted rabbit diet, supplied by M/S Lipton India Ltd, Bangalore (composition and feed analysis reports were provided) was provided, *ad libitum*
Water:	Protected deep bore well drinking water, treated via activated charcoal filter and UV in Aquaguard on-line water filter-cum-purifier provided, *ad libitum*
Housing:	Individually in 3-tier all aluminium cages with wire mesh bottom and common self-draining litter trays.
Environmental conditions:	Temperature: 22 ± 3 °C Humidity: 40 – 70 % Air changes: 10 – 15/h Natural lighting supplemented with fluorescent lighting 12 hours light/dark cycle

B. STUDY DESIGN

In life dates: not reported

Animal assignment and treatment:
In a developmental toxicity study, groups of presumed mated female New Zealand White rabbits were administered once daily by gavage, glyphosate (batch no.: 60, purity 96.8 %) in 0.5 % carboxymethylcellulose (dose volume 2 mL/kg bw) at dose levels of 0 (vehicle control), 20, 100 or 500 mg/kg bw/day from day 6 to day 18 of pregnancy. Dosages for individual animals were calculated from day 6 and adjusted daily according to body weight. Dose levels were based on the findings of preliminary studies.

In a preliminary dose-range finding study, one male rabbit/dose group was administered glyphosate

technical dissolved in 0.5 % carboxymethylcellulose (dose volume 2 mL/kg bw) by gavage at dose levels of 0 (control), 10, 20, 50, 500 or 1000 mg/kg bw/day for 13 days. Doses of ≥ 500 mg/kg bw/day resulted in loss in body weight and in feed intake and the 1000 mg/kg bw/day test animal died on day 9 of treatment.

In a second dose-range finding study, one pregnant rabbit was administered 500 mg/kg bw/day glyphosate from day 6 to 18 of gestation and the findings compared with that of 20 historical control animals. Caesarean section and terminal necropsy was performed on day 28. There were no signs of toxicity from the treatment; body weight gain was greater (26 % more than the historical control mean) but notable apparent treatment-related changes were substantial reduction in feed intake (34 % of historical control mean) and reduced litter size in the test female (4) compared with the historical control mean (7).

Observations
All animals were observed twice daily for onset and duration of signs of toxicity and for mortality. All animals in the experiment that died, were killed moribund or killed at termination were subjected to *post mortem* gross pathological examination. Tissues with gross lesions were preserved for histopathological examination as necessary.

Body weight
Individual body weights were recorded on days 0, daily from days 6 – 18 and on day 28 of gestation.

Food consumption and compound intake
Food consumption was recorded on days of weighing throughout gestation.

Sacrifice and pathology
On day 28 of pregnancy, all surviving dams were subjected to *post mortem* examinations and pups were delivered by Caesarean section. The ovaries and uteri were excised and weighed and maternal and foetal data were recorded. The maternal data determined were pregnant/non-pregnant, uterine weight, the number of corpora lutea, the number of implantations, the number of embryonic and foetal resorptions. The foetal data recorded were the number of dead/abnormal/live foetuses, individual foetal weight and sex.

Litter parameters
All the foetuses were examined for external, visceral and skeletal abnormalities employing appropriate techniques. Live young were euthanised with ether and visceral organs examined by a modified Wilson technique. Skeletal assessments were performed after appropriate preparation including staining in Alizarin Red. Structural changes were presented as variants, minor and major malformations.

Statistics
Statistical methods employed included the following. Maternal body weight and weight gain, feed intake, number of corpora lutea, number of implantations and mean foetal weight were analysed by Bartlett‘s test followed by ANOVA and Dunnett’s test. Day ‘0’and absolute body weight data were compared by the Paired Student’s ‘t‘ test. The number and percent embryonic resorptions and foetal resorptions, the number of dead foetuses, the number of abnormal foetuses and percentage pre-implantation and post-implantation loss by Mann Whitney test. Litter size was by Student ‘t‘ test. The sex ratio, number of dams with any resorptions, number of dams with all resorptions and incidence of malformations were analysed by Chi-square test.

The statistical analysis and comparison of individual treatment groups with control value were done at 5 % probability level and the results were designated as significantly higher (+) / lower (-) than control value at $P \leq 0.05$.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS

Not reported.

B. FOOD CONSUMPTION

During the dosing period, feed consumption was significantly reduced (31 %) in females receiving the 500 mg/kg bw/day dose compared to the controls (see table below). Feed consumption during the post-treatment period did not show significant intergroup differences.

Table 5.6.2-43: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Summary of food consumption (mean ± SD)

Parameter	Historical positive control#	Dose Group (mg/kg bw/day)			
		0 (control)	20	100	500

Day 0 - 28	96 ± 22.5	107 ±27.3	113 ± 18.2	108 ± 24.4	92 ± 37.9

Treatment with Acetylsalicylic acid (ASA) at 200 mg/kg bw (treatment: day 6-18; post-treatment: day 18-28)
* Significantly lower than controls by Dunnett's test P≤0.05

C. MORTALITY

The four and eight deaths observed in the mid- and high-dose group were considered to be treatment-related by the study director. However, the two confirmed misdosings in the control, the absence of signs of toxicity at 100 mg/kg bw/day and the absence of mortality in this dose range in the considerably high number of parallel studies shed serious doubt on a relation to treatment at this dose level. Further, various findings at gross necropsy were noted in the lungs and trachea for the 100 and 500 mg/kg bw/day dose groups; these findings suggest possible gavage errors, which could be responsible for some of the deaths observed at these doses and and are not appropriately discussed in the report. The number of deaths clearly not attributable to gavage dosing errors for each dose group fall within the range of historical control deaths for this laboratory.

Table 5.6.2-44: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Summary of mortality in dams

Parameter	Dose Group (mg/kg bw/day)			
	0 (control)	20	100	500
Mated females	26	17	16	15
Dead during treatment	1*	0	4 (1)	5 (2)
Died post-treatment	1*	0	0	3
Total number of deaths (historical control range 1-4)	2 (2)	0	4 (1)	8 (5)
% mortality	7.7	0.0	25.0	53.3

* Animal died due to wrong gavaging
Parentheses indicate number of deaths with necropsy reporting lung/trachea findings suggestive of gavage errors, such as spillage of gavage fluid into the trachea and lungs.

D. CLINICAL OBSERVATIONS

Signs of toxicity were observed at the 500 mg/kg bw/day dose group and were predominantly

gastrointestinal effects, which included soft stool/liquid faeces and soft stool with mucus. Further signs of toxicity were rales, weakness, dyspnoea and ocular discharge.

Table 5.6.2-45: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Summary of relevant clinical signs in dams

Parameter / clinical sign	Dose Group (mg/kg bw/day)			
	0 (control)	20	100	500
Mated females	26	17	16	15
Pregnant at termination	20	13	12	6
Rales	1	0	0	3
Soft stool with mucus	0	0	0	2
Soft stool/liquid faeces	0	0	1	12
Weak	0	0	0	2
Ocular discharge	0	0	0	1
Dyspnoea	0	0	0	1

E. BODY WEIGHT

No treatment-related and dose-related significant changes were observed in maternal body weight and body weight gain between the control, low- and mid-dose groups. In the high-dose group, initial body weight and body weights at the different time intervals were significantly lower than in the control group.

Table 5.6.2-46: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Summary of maternal body weight data (mean ± SD)

Parameter	Historical positive control#	Dose Group (mg/kg bw/day)

** Significantly higher than controls by Dunnett's test P≤0.05

F. PATHOLOGY

Necropsy

Gross examination of dams at *post mortem* did not identify any treatment-related effects. However, various findings were noted in the lungs and trachea for the 100 and 500 mg/kg bw/day dose groups which suggest possible gavage errors and issues with animal husbandry; 2/2, 0/0, 1/4, and 5/8 deaths attributable to dosing errors at 0, 20, 100 and 500 mg/kg bw/day, respectively. There include gavage needle puncture/damage, and spillage of gavage fluid into the trachea and lungs.

Observations on the ovary and uterus
A total of 20, 13, 12 and 6 pregnant females survived to termination and 134, 80, 78 and 28 foetuses were recorded for the 0 (control), 20, 100 and 500 mg/kg bw/day dose groups, respectively, and were included in the assessment. Litter size at caesarean necropsy was comparable in all treatment groups. Total litter loss (complete resorptions) was recorded for one female in the 500 mg/kg bw/day dose group; otherwise, the incidence of dams with any resorptions did not show any treatment-related differences.

There were no significant intergroup differences in the mean numbers of corpora lutea, pre-implantation and post-implantation losses and resorptions (embryonic and foetal).

Table 5.6.2-47: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Summary of maternal observations

Parameter	Historical positive control#	Dose group (mg/kg bw/day)

\# Treatment with acetylsalicylic acid (ASA) at 200 mg/kg bw
Parentheses indicate number of deaths with necropsy reporting lung/trachea findings suggestive of gavage errors

G. DEVELOPMENTAL PARAMETERS
Number and viability of foetuses
Because of the large number of maternal deaths at 500 mg/kg/day (and thus, the reduced number of total litters), the total number of foetuses was substantially less in this dose group compared to the other dose groups. However, the mean litter size, the mean numbers of abnormal, dead or live foetuses and the sex ratios of foetuses did not show any significant treatment-related differences. Glyphosate also did not cause an increase in the number of foetal deaths in utero (see table below).

Foetal body weights
Although foetal body weights in the 20 and 100 mg/kg/day dose groups were reported to be significantly different from control, the weights were increased, the changes were less than 10 % of control values and no dose-response across treatment groups was evident. Thus, the foetal body weight differences observed in these two dose groups are biologically inconsequential with respect to adverse effects.

Table 5.6.2-48: Glyphosate technical: Teratology study in the rabbit ([redacted] 1993): Mean litter data at caesarean section

	Historical positive control#	Dose group (mg/kg bw/day)

SD = standard deviation
* Significantly higher than controls by Dunnett's test P≤0.05

External, visceral and skeletal examination

The incidence of major external malformations did not identify any treatment-related differences; further, none of the external malformations occurred in the highest dose group.

Visceral examination noted no significant treatment-related incidences of minor malformations or variants. Major visceral malformations primarily affected the heart, but occurred in single incidences and showed no dose-response. The exception was dilated heart, which was reported in four foetuses of 3 litters in the 20 mg/kg bw/day dose group, 4 foetuses (3 + 1) from 2 litters of the 100 mg/kg bw/day dose group and all foetuses (4) of one litter and one foetus of another litter at the 500 mg/kg bw/day (Statistically significant $P \leq 0.05$). The terminology used to describe the heart malformations in this study is different from that typically employed in teratology research (e.g., dilated heart, seal-shaped heart). Consequently, what is meant by the description "dilated heart" is not well defined and not documented with photographs or retained tissue sections or slides. How this malformation might relate to others reported in the heart (i.e., dilated left or right ventricle, seal-shaped heart, cardiomegaly) is not clear. Further, because too few foetuses were available for examination in the high dose group, it cannot be determined whether these defects exhibited a true dose-related increase. It is important to note, however, that only 2 litters exhibited major visceral malformations in the high dose group. Additionally, these findings were found in the presence of extensive maternal toxicity, evidenced by reduced food consumption and body weight gains in the few animals that survived this dose level, clinical signs, and substantial deaths.

Major, minor and skeletal malformations did not show any clear treatment-related findings and appeared to be incidental.

III. CONCLUSIONS

Glyphosate technical was considered not to be teratogenic in this developmental toxicity study in rabbits. The incidence of one undefined visceral effect, "dilated heart", is not consistent with identification of visceral malformations described in Appendix 35 of the report (Protocol for Visceral Evaluation), which identifies four separate visceral malformations within this cluster of findings. This group of malformations was increased at the highest test dose and was present at lower dose levels, but there were too few foetuses present in the high dose group to corroborate a dose-response relationship. Further, foetal findings at the highest test dose were observed in the presence of extensive maternal toxicity that exceeded guideline recommendations for a high dose. The NOAEL for maternal toxicity was 100 mg/kg bw/day based on mortalities at dose levels of ≥ 100 mg/kg bw/day. Mortality and clinical signs of toxicity including reduced feed consumption and soft faeces and reduced body weight gain during the dosing period one incidence of complete resorptions at the 500 mg/kg bw/day dose level. The NOAEL for foetotoxicity and teratogenicity was ≤ 20 mg/kg bw/day based on occurrence of several types of malformations all grouped together under "dilated hearts".

2. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered invalid due to numerous weaknesses including a small number of litters for

examination (low pregnancy rate at all dose levels, lethality in mid and high dose dams), high apparent gavage error rate resulting in mortality, and other reporting deficiencies. The maternal mortality rate for deaths not attributable to garage errors falls within the range of historical control mortalities from this laboratory. The percentage of foetuses with 'dilated heart' was significantly increased at all dose levels. However, the absolute number of affected foetuses and litters is quite small and did not show a marked difference between the treated groups. Unfortunately, the reporting of "dilated heart" in the study report is not consistent Appendix 35 "Protocol for Visceral Evaluation" in this report, which notes four different categories of dilated heart; (i) dilation of the ventricle of the olfactory bulb, (ii) dilation of the lateral ventricle, (iii) dilation of the third ventricle, and (iv) dilation of the fourth ventricle. Given the reporting is not consistent with the detail of the protocol, a low level of confidence is placed in the reporting of these different endpoints.The diagnosis 'dilated heart' was not defined in this study report, does not follow "Appendix 35 Protocol for Visceral Evaluation", and neither criteria used for this diagnosis nor measurements of the heart were provided. In addition, this group of reported malformations lacks a clear dose-response noting that litters, not foetuses, are the experimental unit in developmental toxicity studies; dilated heart foetuses (litters) were 0 (0), 4 (3), 4 (2), and 5 (2) across 0, 20, 100 and 500 mg/kg bw/day, respectively. The inconsistency of malformation terminology in this study report when compared both with other studies and this laboratory's own visceral evaluation terminology in Appendix 35, suggests that interpreting this group of malformation types within this study is not appropriate or justified. Given the inaccuracies in reporting of heart findings and lack of dose-response, the offspring NOAEL in disregarding these endpoints, should be 100 mg/kg bw/day, due to the high dose proving to be well in excess of a limit dose. Similarly, the maternal NOAEL is 100 mg/kg bw/day, since the maternal mortality at this dose is within the range of historical controls for this laboratory. However, little if any weight should be placed on this study due to its many shortcomings. The applicant believes this study should be disregarded as unreliable for the above mentioned reasons.

Assessment and conclusion by RMS:

1. Information on the study

2. Full summary

In the preliminary study Part III, CHV/40, included with the definitive study report, CHV/45/901303, groups of two non-pregnant does were dosed with 1000 mg/kg bw/day glyphosate for seven days and 750 or 500 mg/kg bw/day for 13 days. Liquid/soft faeces were noted for all animals.

In the preliminary study Part II, CHV/39, included with the definitive study report, CHV/45/901303, groups of six pregnant does were dosed with 0, 100, 250 or 625 mg/kg bw/day glyphosate on gestation days 7-19. Signs of reaction to treatment were restricted to gastro-intestinal disturbances and consisted of a dosage-related increase in the incidence of females showing soft/liquid faeces, and two high dose deaths.

In a definitive developmental toxicity study, CHV/45/901303, groups of 16 - 20 time-mated female New Zealand White rabbits were administered glyphosate acid in 1% methylcellulose once daily by gavage at dose levels of 0 (vehicle control), 50, 150 or 450 mg/kg bw/day from day 7 to day 19 of pregnancy (mating = day 0). All animals were observed daily for clinical signs and mortality, and body weights and food consumption were measured on days 1, 7, 9, 11, 15, 20, 24 and 29 of gestation. On day 29 of gestation, the does were sacrificed and a gross necropsy was performed. The ovaries and uteri were examined to determine the number of corpora lutea, the number and distribution of live young, the number and distribution of embryonic and /foetal deaths, individual foetal weight and foetal abnormalities. All live foetuses were examined for external, visceral and skeletal abnormalities.
Observations recorded included one death at 450 mg/kg bw/day following abortion. Reduced food intake during the treatment period and reduction in body weight gain from days 11 – 19 of pregnancy were noted at 150 and more pronounced at 450 mg/kg bw/day. Clinical signs included a dose-related increase in the number of females showing soft/liquid faeces (gastrointestinal disturbances) and slight reductions in food consumption and body weight at 150 and 450 mg/kg bw/day.

Glyphosate was not teratogenic in this developmental toxicity study in rabbits.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate acid
Description:	White solid
Lot/Batch #:	206-JAK-25-1
Purity:	98.6 %
Stability of test compound:	Stable over the duration of the study
Vehicle:	1 % methylcellulose
Test Animals:	
Species:	Rabbit
Strain:	New Zealand White
Source:	[redacted]
Age:	11-24 weeks (on delivery)
Sex:	Female
Weight at dosing:	Females: 3582 – 3709 g (group mean values)
Acclimation period:	7 days
Diet/Food:	SQC Standard rabbit diet (Special Diet Services Ltd., Essex, UK), *ad libitum*
Water:	Mains drinking water, *ad libitum*
Housing:	Individually in metal cages equipped with sheet stainless steel sides, back and top, a stainless steel wire front and an aluminium perforated floor panel; individual undercage plastic trays lined with absorbent paper
Environmental conditions:	Temperature: 19 ± 1 °C Humidity: 49 ± 15 % Air changes: Not recorded Natural lighting supplemented with artificial lighting from 07 – 21:00 hours

B. STUDY DESIGN

In life dates: 14 -12-1989 – 02-03-1990

Animal assignment and treatment:
In a developmental toxicity study, groups of 16 - 20 time-mated female New Zealand White rabbits were administered glyphosate in 1 % methylcellulose (dose volume 5 mL/kg) once daily by gavage at dose levels of 0 (vehicle control), 50, 150 or 450 mg/kg bw/day from day 7 to day 19 of pregnancy. Dose volumes were calculated for individual animals on day 7 and adjusted according to body weight on days 9, 11 and 15. The day of mating was considered as day 0. Dose levels were based on the findings of a preliminary study.

Dosing formulations were prepared daily and administered within 3 hours of preparation.

Observations

All animals were regularly handled and observed daily for overt changes or signs of reaction to treatment. Animals that died or were killed for animal welfare reasons were weighed and subjected to *post mortem* examination.

Body weight
Individual body weights were recorded days 1, 7, 9, 11, 15, 20, 24 and 29 of gestation.

Food consumption and compound intake
Food consumption was recorded on days of weighing throughout gestation.

Sacrifice and pathology
On day 29 of pregnancy all surviving does were subjected to *post mortem* examinations for congenital abnormalities and gross pathological changes in maternal organs.
The ovaries and uteri were examined to determine the number of corpora lutea, the number and distribution of live young, the number and distribution of embryonic and /foetal deaths, individual foetal weight and foetal abnormalities. Embryonic/foetal deaths were classified as early, late or abortions.

Litter parameters
Live young were examined for external, visceral and skeletal abnormalities employing appropriate techniques. Live young were killed by intrathoracic injection of pentobarbitone sodium then weighed and dissected for examination of visceral abnormalities. Where appropriate, suspected abnormalities were further examined by alternative procedures such as microdissection and histopathology to clarify initial observations. Pups were fixed in industrial methylated spirit, the heads sliced along the line of the frontoparietal suture and the brain examined for abnormalities before clearing and staining by the modified Dawson technique of the carcasses for skeletal examination. Structural changes were presented as malformations, anomalies or variants.

Statistics
Two-tailed tests for significance were performed on litter data only, and significance at 1% and 5% were reported. Mean values of litter size, pre and post-implantation loss, litter weight, mean foetal weight and the incidence of anomalous offspring were analysed by the Kruskal-Wallis test. Intergroup comparisons were made by the non-parametric equivalent of the Williams' test following a significant h-statistic. Where 75% of the values for a given variable consisted of one value, a Fisher's exact test was used.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The analysis of the dosing formulations taken at the first dosing showed the mid- and high-dose group to be within 6% of the nominal dose whilst the low-dose group was 19 % below the nominal dose; however, a renalysis on day 19 showed the concentration to be 5 % above the nominal dose.

B. FOOD CONSUMPTION
During the dosing period, females receiving 150 and 450 mg/kg bw/day showed reduced food consumption compared to the controls. A slight reduction was evident from days 11 – 19 at 150 mg/kg bw/day (approximately 12% compared with controls) and throughout the treatment period for the 450 mg/kg bw/day dose group (6-17% during days 7-19).

Table 5.6.2-50: Glyphosate technical: Teratology study in the rabbit ([redacted], 1991): Summary of mean food consumption (g/rabbit/day)

	Dose Group (mg/kg bw/day)			
	0 (control)	**50**	**150**	**450**
Mated females	19	19	16	20

Days 1-6	142	143	141	152
Days 7-8	143	154	150	135
Days 9-10	146	148	148	132
Days 11-14	153	149	134	129
Days 15-19	148	151	131	123
Days 20-23	142	154	149	149
Days 24-28	131	143	153	166

C. MORTALITY

There was one death in the 450 mg/kg bw/day dose group on day 20 following signs of abortion on day 19 and signs of gastrointestinal disturbance, manifested as soft/liquid faeces, severe reduction in food consumption and body weight loss from the onset of treatment. Two other deaths (a broken hind leg and an incidence of congenital abnormality) were unrelated to the treatment and were eliminated from the study assessment.

D. CLINICAL OBSERVATIONS

Clinical signs included a dose-related increase in the number of females showing soft/liquid faeces (gastrointestinal disturbances) and signs of lack of appetite (off feed/reduction in food consumption) at 150 and 450 mg/kg bw/day (see below).

Table 5.6.2-51 Glyphosate technical: Teratology study in the rabbit ([redacted], 1991): Summary of maternal performance and relevant clinical signs

Parameter	Dose Group (mg/kg bw/day)			
	0 (control)	50	150	450

Off-feed	8	6	10	9
Reduced faecal output	9	8	11	12
Soft/liquid faeces	0	2	5	13

Only animals with live young included

E. BODY WEIGHT

A slight reduction in body weight gain was noted from day 11 of pregnancy to termination of treatment in the 150 and 450 mg/kg bw/day dose groups, which coincided with the reduction in food consumption during the same period (see table below).

Table 5.6.2-52Glyphosate technical: Teratology study in the rabbit ([redacted], 1991): Summary of body weight data (group means)

Day 29	3999	4084	3975	4103

F. PATHOLOGY

Necropsy

Gross examination of does at *post mortem* did not identify any treatment-related effects.

Observations on the ovary and uterus

A total of 18, 12, 15 and 13 pregnant females survived to termination and 163, 104, 112 and 95 foetuses were recorded for the 0 (control), 50, 150 and 450 mg/kg bw/day dose groups respectively. Litter size at caesarean necropsy was comparable in all treatment groups. Total litter loss was recorded for one female of the 450 mg/kg bw/day dose group which aborted on day 19 and died and also for one female at 50 mg/kg bw/day. One female at 150 mg/kg bw/day aborted 1/9 foetuses.

There were no significant intergroup differences in the numbers of corpora lutea, implantations, pre-implantation loss, foetal sex ratios or foetal weights. There was a statistically significant increase in embryo/foetal death and post-implantation loss at all exposure levels. The study investigators questioned the biological significance of these findings for several reasons: 1) No dose-response pattern was evident, 2) the control value was at the lower end of the historical control range, while those of the exposed groups were at the higher end, and 3) the values in all groups were within or slightly above the historical control range. The latter two statements are supported by the historical control data provided in the study report (page 32). Although embryo/foetal death was within the historical control range, post-implantation loss was above the historical control values in the high-dose group, and both of these parameters were statistically significant ($p<0.01$) at the high dose.

G. DEVELOPMENTAL PARAMETERS

Number and viability of foetuses

There were 18, 12, 15 and 13 viable litters at 0, 50, 150 and 450 mg/kg bw/day, respectively. The concurrent control showed low mean values for embryonic deaths and post implantation losses when compared with historical control values. When compared with these historical data as noted above, mean values in the treated groups were within the expected range; therefore, it was concluded that no adverse effect on foetal survival was attributed to glyphosate.

Foetal body weights

There was a dose-related reduction in mean foetal weight on a litter basis in all treated groups (not statistically significant) compared with the control; however, the mean individual foetal weight was not affected.

External, visceral and skeletal examination

Malformations were slightly increased in the 150 and 450 mg/kg bw/day dose groups compared to controls and appeared to be associated with an apparent increase in malformations of the thoracic region. However, neither the incidence nor the percentage of malformed foetuses was outside the historical control range and the values were not statistically different from concurrent control values. Several of the cardiovascular malformations that were observed, particularly in the high-dose group, occurred in the same animals and are related to a single morphogenetic mechanism (i.e. displacement of the developing aorticopulmonary septum), which is likely to adjust during the first two weeks of postnatal life. These related findings, which often cluster together, included dilated/narrow aorta and narrow/dilated pulmonary artery; interventricular septal defect; and disproportionately sized right and left ventricles. These findings were observed (often in clusters) in the historical control data that were provided by the conducting laboratory. Individual presentation of these malformations in tables when the malformations occurred together in the same foetus and are due to the same mechanisms and artificially inflates the sense that there is a much stronger cardiac effect than is actually present.

The cardiac malformation observed with greatest frequency in this study was interventricular septal defect. The number of foetuses and litters with ventricular septal defects were 1, 1, 1 and 4 in the 0, 50, 150 and 450 mg/kg bw/day dose groups, respectively. Comparison of the historical control data (see table below) shows that the heart findings (when presented on a percent individual and/or litter incidence basis) were slightly outside of the historical background range from 13 studies conducted during the same period. However, the disparity in values is a consequence of the small numbers of litters in the study report. If the data are displayed as a fraction (rather than a percentage), then the number of litters affected were 1/18, 1/12, 1/15, and 4/13 in the 0, 50, 150, and 450 mg/kg/day dose groups, respectively. The historical control range is 0/19 – 3/13. Thus, the findings at the high dose are barely outside of the historical control range. Further, they were observed in conjunction with clear signs of maternal toxicity (reduced food consumption, body weight gains and increased clinical signs).

The other cardiovascular finding found in this study not related to the morphogenetic mechanism involving formation of the spiral septum is retroesophageal right subclavian artery. This finding was also observed regularly throughout the historical period. It is not uncommon and is oftentimes an inconsequential anatomical difference in vascular arrangement. At autopsy this condition is found in 0.5 – 2.0 % of subjects.

The malformations of the cranial region, the lumbar and the lumbar/sacral regions did not show any treatment-related trend and are considered to be incidental. The incidences of anomalies and variants did not suggest any treatment relationship. The incidence of foetuses with reduced ossification did not show

any dose-relationship; however, lower foetal weights were observed for the 450 mg/kg bw/day dose group with reduced ossification.

The observed foetal malformations and anomalies are summarised in the following table.

Table 5.6.2-54Glyphosate technical: Teratology study in the rabbit ([redacted], 1991): Summary of foetal examination

III. CONCLUSIONS

Study conclusion:
Glyphosate was not teratogenic in this developmental toxicity study in rabbits. The NOAEL for maternal toxicity was 50 mg/kg bw/day based on clinical signs of toxicity including reduced feed consumption and body weight gain and soft/liquid faeces during the dosing period. The NOAEL for foetotoxicity was 150 mg/kg bw/day based on statistically significantly increased embryo/foetal deaths and post implantation loss. The NOAEL for teratogenicity was 450 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable, though treatment duration covered the period from implantation through organogenesis rather than through to the day prior to necropsy, as recommended in the current OECD 414 guideline. In this study, there was a significant increase in embryonic death and post-implantation loss in treated groups compared to controls, however without a clear dose-relationship. Regarding the post-implantation losss, values for the low and high dose groups are outside the historical control range. The cardiac malformation observed with greatest frequency in this study was the interventricular septal defect. At 450 mg/kg bw/day this effect was outside the historical control range (4.2 % compared to 0.66 % in historical controls). Taken into account the high post implantation loss at the same dose level, the incidence of additionally cardiac malformation may be covered. At mid dose level, foetuses with an higher incidence of retrooesophageal right subclavian artery were reported. However, this effect has to be considered equivocal, because no clear-dose relationship could be established.
In conclusion, the NOAEL for maternal toxicity is considered 50 mg/kg bw/day based on slightly reduced food consumption, slightly reduced body weight gain and soft/liquid faeces at 150 mg/kg bw/day. The NOAEL for developmental toxicity is considered to be 150 mg/kg bw/day based on the post implantation loss, late embryonic death and an increase in cardiac malformations at 450 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/016**
Report author	[redacted]
Report year	1989
Report title	Rabbit Teratology Study with Glyphosate Technical
Report No	1086

Document No	Not reported
Guidelines followed in study	OECD 414 (1981)
Deviations from current test guideline (OECD 414, 2018)	Group size smaller than required, dosed from day of implantation through the period of organogenesis, rather than through to day prior to necropsy, no uterine weight reported, no maternal necropsy findings reported. Deviations from the current version of OECD 414 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 414.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities[1,2]	Yes
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

This developmental toxicity study in rabbits is limited in its extent of documentation. Glyphosate Technical was administered by gavage to three groups of 15 successfully mated New Zealand albino rabbits each, at doses of 125, 250, and 500 mg/kg bw/day from gestation day 6-18 (mating = day 1). A further group of 15 animals was exposed to the vehicle to serve as control.

No adverse effects related to test substance treatment were observed in any animals of the low and mid dose group. Mean maternal body weights and food consumption were lower in the high dose group, however clinical signs of systemic toxicity were not observed at any dose. In the high dose group, two cases of total abortion were considered to be related to test substance treatment.

The mean number of viable implants (foetuses) per litter was lower in the high dose group and the mean number of external, visceral and skeletal malformations as well as the mean number of variations was higher in the high dose group compared to the control group. No differences in the examined developmental parameters were found in the low and mid dose groups, although a dose-related increase in the numbers of malformations and variations was noted.

II. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White amorphous powder
Lot #:	38
Purity:	95 %
Stability of test compound:	Not reported
Vehicle:	0.1 % gum acacia in water
Test Animals:	
Species:	Rabbit
Strain:	New Zealand White
Source:	[redacted]
Age:	24 - 28 weeks

Sex:	Females	
Weight at dosing:	1.50 – 2.00 kg	
Acclimation period:	6 days	
Diet/Food:	Pelleted rabbit feed supplied by Lipton India Ltd., Bangalore, India	
Water:	Tap water, *ad libitum,* supplied in polypropylene bottles by Maharashtra Industrial Development Corpn., New Bombay	
Housing:	Individually in stainless steel cages equipped with food and water dispensers and stainless steel grate at bottom	
Environmental conditions:	Temperature:	20 ± 3 °C
	Humidity:	30 to 70 %
	Air changes:	not reported
	12 hours light/dark cycle	

B. STUDY DESIGN

In life dates: 1989-07-03 to 1989-11-02

Animal assignment and treatment:
Groups of 15 New Zealand White female rabbits received doses of 0, 125, 250 and 500 mg/kg bw/day test substance in 0.1% gum acacia in water by gavage from gestation day 6-18 after successful mating with adult vigorous males. The day of mating was taken as the 1st day of pregnancy.

Diet preparation and analyses
For each dose level, dosing solutions were prepared in 0.1 % gum acacia in water as vehicle.

Clinical observations
A check for clinical signs of toxicity, ill-health or behavioural changes was made twice daily (before and after dosing) during the dosing period.

Body weight
Individual body weights were recorded on days 0, 6, 12, 18, 23, and 29 (at necropsy). Changes in body weight were calculated and recorded as group maternal weight changes for the periods of days 0-6 (pre-exposure), 6-12, 12-18, 18-23, 23-29 and 18-29 (post-exposure observation period).

Food consumption
Food consumption was recorded on days 0, 6, 12, 18, 23, and 29.

Sacrifice and pathology
Females were euthanatised by carbon dioxide asphyxiation on day 29 of gestation and examined for any abnormalities that would affect pregnancy.
The ovaries and uteri were removed, the uteri were weighed, and the ovaries were examined for the number of corpora lutea and uteri for the number and position of implants and dead or live foetuses. Uteri from non-gravid females were placed in 10% ammonium sulfide solution for detection of early resorptions.

Developmental parameters
Each rabbit foetus was removed from the uterus and was killed by injection of pentobarbitone. All live foetuses were weighed and examined for external malformations including cleft palate and variations. All live foetuses were examined for thoracic and visceral abnormalities, and each foetus was sexed. Following visceral examination, all foetuses were eviscerated and processed for skeletal staining with Alizarin Red S.

All foetuses were decapitated and heads were fixed in Bouin's solution for examination of craniofacial structures.

Statistics
Not reported.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
Not reported.

B. FOOD CONSUMPTION
Mean food consumption in the low and mid dose groups was comparable to that in the control group throughout the study period. Significantly lower food consumption (~17% lower mean food consumption compared to control, low or mid dose group) was observed in the high dose group starting with the day of treatment throughout the rest of the observation period.

Table 5.6.2-55: Glyphosate technical: Teratology study in the rabbit ([redacted], 1989): Food consumption (mean ± SD)

Parameter		Dose Group (mg/kg bw/day)			
		0 (control)	125	250	500
Food consumption (g/rabbit/day)					
No of dams included in assessment		15	15	15	15
Day 0 – 6	(Pre-treatment)	92.3 ± 8.55	97.2 ± 6.56	96.7 ± 6.73	100.1 ± 6.32
Day 6 – 12	(Treatment)	98.7 ± 6.53	99.5 ± 5.76	100.7 ± 6.30	82.7 ± 6.61
Day 12 – 18	(Treatment)	98.6 ± 6.62	98.4 ± 4.34	94.4 ± 4.58	80.9 ± 4.87
Day 18 – 29	(Post treatment))	192.5 ± 7.69	202.5 ± 8.93	205.3 ± 7.07	162.1 ± 12.03

C. MORTALITY
None of the rabbits died during the study period.

D. CLINICAL OBSERVATIONS
No toxic symptoms were observed in any of the animals during the study.

E. BODY WEIGHT
Mean body weights of animals in the low and mid dose group were comparable to those in the control group. In the high dose group, the mean maternal weight increase was lower for each of the observation periods between days 12-29 compared to controls, but no statistical comparison was provided in the report.

Table 5.6.2-56: Glyphosate technical: Teratology study in the rabbit ([redacted], 1989): Maternal body weight changes (mean ± SD)

Parameter		Dose Group (mg/kg bw/day)			
		0 (control)	125	250	500
Body weight change (g)					
No of dams included in assessment		15	15	15	15
Day 0 – 6	(Pre-treatment)	166.5 ± 3.35	160.5 ± 12.15	153.6 ± 19.91	156.3 ± 9.15
Day 6 – 12	(Treatment)	14.0 ± 5.41	8.0 ± 5.09	13.0 ± 7.06	10.1 ± 7.08
Day 12 – 18	(Treatment)	61.7 ± 21.07	73.0 ± 18.11	69.5 ± 18.45	40.0 ± 16.15

Day 18-29	(Post exposure)	116.7 ± 39.56	125.9 ± 25.51	109 ± 22.44	68.9 ± 15.99

F. PATHOLOGY

Necropsy

No abnormalities that could affect pregnancy were reported at maternal necropsy.

Observations on the ovary and uterus

Two animals of the high dose group aborted.

Table 5.6.2-57: Glyphosate technical: Teratology study in the rabbit ([redacted], 1989): Gestational parameters and foetal weights

Gestational parameter	Dose level (mg/kg bw/day)			
	0	125	250	500
No. of mated females	15	15	15	15
No. of early deliveries	0	0	0	0
No. of abortions	0	0	0	2
No. of females without foetuses	0	0	0	2
No. nonpregnant at termination	2	1	1	3
No. of litters	13	14	14	12
Mean no. of corpora lutea per doe ± SD	10.0 ± 1.69	10.1 ± 1.60	10.3 ± 1.44	9.8 ± 1.57
Mean no. of total implants per litter ± SD	9.0 ± 1.20	9.3 ± 1.33	9.4 ± 1.12	8.5 ± 1.05
Mean % pre-implantation loss ± SD	21.3 ± 32.4	14.9 ± 24.09	14.7 ± 24.38	13.1 ± 6.34
Mean no. of viable implants per litter ± SD	7.3 ± 3.10	8.0 ± 2.59	8.0 ± 2.59	5.2 ± 3.03
Mean no. of non-viable implants per litter ± SD	0.07 ± 0.26	0.13 ± 0.35	0.27 ± 059	1.4 ± 2.20
Mean no. of early resorptions per litter ± SD	1.7 ± 3.22	1.1 ± 2.53	1.0 ± 2.56	1.9 ± 2.43
Sex ratio (% males) ± SD	44.4 ± 20.17	49.2 ± 6.90	49.7 ± 11.45	50.1 ± 13.00
Mean foetal body weight per litter ± SD	40.6 ± 16.6	47.1 ± 0.95	47.5 ± 1.38	48.7 ± 1.87

G. DEVELOPMENTAL PARAMETERS

Number and viability of foetuses

The mean number of viable implants (foetuses) per litter was lower in the high dose group, and accordingly, the mean number of non-viable implants (foetuses) per litter was greater in the high dose group, but no statistical comparisons were provided in the report.

Sex ratio, foetal body weights and placental weights

No differences were noted in the sex ratios, mean foetal body weights, mean number of corpora lutea per dose, mean number of total implants per litter, mean percentage of pre-implantation loss, and mean number of early resorptions between the control and the treated groups. In the high dose group, two dams had no live foetuses due to abortions. However, stasticial analyses were provided in the report.

External, visceral and skeletal examination

No difference was noted in the incidences of maternal animals having foetuses with external, visceral and/or skeletal malformations in the low and mid dose groups when compared with the controls. In the high dose group, the incidences of external, visceral and skeletal malformations were higher than that in the control group. With regard to the heart malformations, 0, 1, 1, and 2 interventricular septal defects were observed in the 0, 125, 250, and 500 mg/kg bw/day dose groups.

A similar pattern was seen in the variations observed externally, viscerally and skeletally; in the high dose group, the total number of observed variations was higher than those of the control, low or mid dose groups.

The increase in malformations and variations observed in the high dose group occurred in the presence of maternal toxicity (reduced food consumption and body weight gains). Further, this was at a dose (500 mg/kg bw/day) that caused significant toxicity, including mortality, in another rabbit developmental study. However, stasticial analyses were not provided in the report.

Table 5.6.2-58: Glyphosate technical: Teratology study in the rabbit ([redacted], 1989): Incidence of foetal malformations and variations

Foetal findings	Dose level (mg/kg bw/day)			
	0	125	250	500

III. CONCLUSIONS

The oral administration of glyphosate to mated rabbits by gavage from gestation day 6-18 resulted in treatment-related changes at 500 mg/kg bw/day. Therefore the NOAEL for reprotoxic and non-reprotoxic effects was considered to be 250 mg/kg bw/day. Considering the significantly reduced food consumption and body weight gain at 500 mg/kg bw/day, the maternal NOAEL is 250 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The NOAEL for maternal and developmental toxicity is considered to be 250 mg/kg bw/day based on reduced food consumption and body weight gain at 500 mg/kg bw/day in does. Developmental effects were visible as foetolethality and several malformations (external, visceral, skeletal) at high dose levels: total number of foetuses per litter with malformations was higher in the groups receiving the mid and high dose lever, but without statistical significance. However, it remains unclear, whether statistical analysis of the data had been performed at all. Ventricular septal defects were noted in 2 out of 12 litters in the high dose group (control incidence 0/13 litters). The higher number of further visceral malformations at the top dose level was due to absent kidneys and postcaval lung lobes. Because no individual data are provided it is not identifiable, whether the malformations described were confined to single foetuses or if the foetuses were multiple malformed.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/017**
Report author	[redacted]
Report year	1981
Report title	Teratological investigation of glyphosate in rats and rabbits
Report No	Not reported
Document No	Not reported
Guidelines followed in study	Not stated (pre-guideline)
Deviations from current test guideline (OECD 414, 2018)	Dosed from day of implantation through the period of organogenesis, rather than through to day prior to necropsy, group size smaller than required, foetal visceral examination apparently not performed, no data on results of foetal skeletal examination, no statistical methods described or used.

Previous evaluation	Not accepted in RAR (2015)
GLP/Officially recognised testing facilities[1,2]	No (GLP was not compulsory at the time of study conduct)
Acceptability/Reliability:	Invalid
Category study in AIR 5 dossier (L docs)	Category 3b

2. Full summary

In a developmental toxicity study, groups of 14-16 time-mated female New Zealand White rabbits were administered glyphosate acid from days 6 to 19 of gestation as a dietary admix. Concentrations of glyphosate in the diet are not stated, but admix of the test item was reported to result in test item intakes of 10.5, 50.7 and 255.3 mg/kg bw/day, respectively. Does were sacrificed in a CO_2 chamber on day 28 of gestation. After opening the uterine horns the total number of implantations, of live, dead and resorbed embryos/foetuses were counted. The mean litter and foetal weights, gestational growth, the mean body weight gain were calculated. During necropsy heart, kidney, spleen and lungs were prepared and fixed in 4 % neutral formalin. For skeletal examination the laboratory's modification of the Staples and Schnell's method was used.

Treatment with glyphosate had no effect on the behaviour and appearance of the animals. Body weight was higher in the treated groups than in the controls. No macroscopic changes were noted in the control and treated does. Glyphosate was not teratogenic in this study. Gross and histopathological examination at scheduled necropsy indicated no abnormalities. Foetal loss was increased in mid and high dose and litter weight was decreased. No other findings were noted.

B. STUDY DESIGN

In life dates: Not stated

Animal assignment and treatment:
In this developmental toxicity study, groups of 14 - 16 time-mated female New Zealand White rabbits were administered glyphosate in the diet from day 6 to day 19 of gestation. Concentrations of glyphosate in the diet are not stated, but admix of the test item was reported to result in test item intakes of 10.5, 50.7 and 255.3 mg/kg bw/day, respectively.
Food pellets were prepared freshly from food sizings of 10 x 30-40 mm size by means of MOM type machine /Simon-Hessen kind. Food was stored at -20 °C till use.

Clinical observations
Not stated.

Body weight
Individual body weights were recorded on days 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26 and 28 of gestation.

Food consumption and compound intake
Not reported.

Sacrifice and pathology
Does were sacrificed in a CO_2 chamber on day 28 of gestation. During necropsy, heart, kidney, spleen and lungs were prepared and fixed in 4 % neutral formalin..

Litter parameters
After opening the uterine horns the total number of implantations, of live, dead and resorbed embryos/foetuses were counted. The mean litter and foetal weights, gestational growth, the mean body weight gain were calculated.

Statistics
Not reported.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
Not reported.

B. FOOD CONSUMPTION
Not reported.

C. MORTALITY
No mortality occurred during the study.

D. CLINICAL OBSERVATIONS
Not reported.

E. BODY WEIGHT
Absolute body weights during gestation were similar across groups. Body weight gains were higher in the treated groups than in the control (see table below).

Table 5.6.2-59: Glyphosate technical: Teratological investigation of glyphosate in rats and rabbits ([redacted], 1981): Summary of body weight data (group means)

Parameter	Dose Group (mg/kg bw/day)			
	0 (control)	11	51	255
Mated females	14	15	14	16
No of animals included in assessment	14	15	14	16
Body weights (g) at				
Day 6	3495	3392	3170	3391
Day 10	3560	3504	3319	3592
Day 16	3719	3668	3462	3720
Day 26	3924	3839	3679	3964
Body weigt gain day 6-26 (g)	426	452	516	578

F. PATHOLOGY
Necropsy
No macroscopic changes were noted in the control and test item-treated does.

Observations on the ovary and uterus
A total of 14, 15, 14 and 16 pregnant females survived to termination and 106, 125, 93 and 119 live foetuses were recorded for the 0 (control), 11, 51 and 255 mg/kg bw/day dose groups respectively. There were no substantial intergroup differences in the numbers of implantations. The incidence of dead foetuses was higher in the mid and high dose than in the controls. The percentage of foetal loss was higher in the mid and high dose than in the controls but without clear dose response. No total litter loss was recorded in any group. Litter size at caesarean necropsy was comparable in all treatment groups.

Table 5.6.2-60: Glyphosate technical: Teratological investigation of glyphosate in rats and rabbits ([redacted], 1981): Summary of litter parameters

Parameter	Dose Group (mg/kg bw/day)			
	0 (control)	11	51	255
No. of mated females	14	15	14	16
Mean No. of implantations/dam	7.64	8.40	7.07	8.00
Mean No. of dead foetuses/dam	0.07	0.07	0.43	0.56
Foetal loss (%)	0.93	0.79	6.06	7.03
Mean No. of live foetuses/dam	7.57	8.33	6.64	7.44
Mean litter weight (g)	273	283	240	254
Mean foetal weight (g)	36.51	34.33	36.47	34.40
Externally abnormal foetuses	0	0	0	0

G. DEVELOPMENTAL PARAMETERS
Number and viability of foetuses

There were 14, 15, 14 and 16 viable litters at 0, 11, 51 and 255 mg/kg bw/day, respectively. There were no substantial intergroup differences in the number of live foetuses. The number of dead foetuses per dam was slightly increased in the mid and high dose group.

Foetal body weights
Mean foetal weights were considered not affected by treatment. But mean litter weights were decreased at 51 and 255 mg/kg bw/day, although a dose response was lacking and no statistical comparisons were undertaken.

External, visceral and skeletal examination
No externally abnormal foetuses were noted in any group. No data on results of skeletal or visceral examinations are provided.

III. CONCLUSIONS

Treatment with glyphosate had no effect on the behaviour and appearance of the animals. Body weight was higher in the treated groups than in the controls. No macroscopic changes were noted in the control and treated does. Glyphosate was not teratogenic in this study. Gross and histopathological examination at scheduled necropsy indicated no abnormalities. Foetal loss and was increased in the mid and high dose, but no statistical analyses were undertaken. Litter weight decreases in a non-dose responsive manner were noted. No other findings were noted.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study is very poorly reported and with major deviations from the recent OECD 414 (treatment duration shorter than required, group size smaller than required, no data on visceral or skeletal examination, no statistics).

Treatment with glyphosate had no effect on the behaviour and appearance of the animals. Body weight was higher in the treated groups than in the controls. No macroscopic changes were noted in the control and treated does. Glyphosate was not teratogenic in this study. Gross and histopathological examination at scheduled necropsy indicated no abnormalities. Foetal loss and litter weight were increased in the mid and high dose, with no statistical analyses undertaken. No other findings were noted. This study is considered invalid.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/018**
Report author	[redacted]
Report year	1980

2. Full summary

In this pilot study technical glyphosate was administered by gavage to groups of 5 pregnant Dutch Belted rabbits each, at doses of 125, 250, 500, 1250 and 2500 mg/kg bw/day from gestation day 6-27 (insemination = day 0). A further group of five animals was exposed to the vehicle (1% aqueous Methocel®) to serve as control. Thus, a step dose-response for mortality was demonstrated with no substantial adverse effects at 250 mg/kg bw/day, yet severe body weight loss and 1/5 does with sponeaneous abortion (terminated in extremis) and death of the remaining 4/5 does at 500 mg/kg bw/day. Earlier time to mortality was dose-dependent at 500, 1250 and 2500 mg/kg bw/day.
Individual clinical observations and body weights were recorded during the study. The animals were either killed on day 28 of gestation, or after they had aborted during the study period. All sacrificed animals or animals found dead were subjected to a gross necropsy. The uteri were examined for number of early and late resorptions and total implantations as well as the number of viable and non-viable foetuses. The number of corpora lutea was also recorded. Foetuses were not examined.
There were no biologically meaningful differences in appearance or behaviour attributable to treatment with the test item at 125 and 250 mg/kg bw/day when compared to the control. One rabbit at 500 mg/kg bw/day group aborted. The four remaining rabbits in this group and all rabbits at 1250 and 2500 mg/kg bw/day died.
There were no biologically meaningful differences in mean maternal body weights at 125 and 250 mg/kg bw/day compared to the control. A severe body weight loss during the treatment period was noted at 500 mg/kg bw/day. A clear dose-response for clinical signs of loose stool/diarrhoes onset, as well as treatment-related increase in severity of these clinical signs across all doses, and as dose-related earlier death at doses greater than 250 mg/kg bw/bay. There were no biologically meaningful differences in the mean number of corpora lutea, total implantations, post-implantation loss or viable foetuses at 125 and 250 mg/kg bw/day. Due to lack of signs of maternal toxicity at 250 mg/kg bw/day and severe maternal toxicity at 500 mg/kg bw/day, a high dose level between 250 and 500 mg/kg bw was considered suitable for the pivotal teratology study.

The oral administration of glyphosate acid to pregnant rabbits by gavage from gestation day 6-27 did not result in maternal toxicity at 125 and 250 mg/kg bw/day; there were no treatment-related effects on pregnancy or foetuses at these dose levels. At 500 mg/kg bw/day one animal aborted and the four remaining animals died. At 1250 and 2500 mg/kg bw/day all animals died.

I. MATERIALS AND METHODS

A. MATERIALS

Test Material:

Identification:	Glyphosate technical
Description:	White powder
Lot/Batch #:	XHJ-64
Purity:	100 %
Stability of test compound:	Not reported

Vehicle:	1 % aqueous Methocel®	
Test Animals:		
Species:	Rabbit	
Strain:	Dutch Belted	
Source:	[redacted]	
Age:	Approx. 6 month	
Sex:	Females	
Weight at first dosing:	2.335 - 3.153 kg	
Acclimation period:	At least 28 days	
Diet/Food:	Purina Rabbit Chow Checkers 5301, *ad libitum*	
Water:	Tap water, *ad libitum*	
Housing:	Individually in suspended wire mesh cages	
Environmental conditions:	Temperature:	controlled but exact values not reported
	Humidity:	controlled but exact values not reported
	Air changes:	Exact values not reported
	Light controlled	

B. STUDY DESIGN

In life dates: 1979-03-02 to 1979-03-30

Animal assignment and treatment:
Thirty female Dutch Belted rabbits were artificially inseminated and randomly assigned to treatment groups of 5 animals. The day of insemination was designated day 0 of gestation. The rabbits received daily doses of 0, 125, 250, 500, 1250 and 2500 mg/kg bw/day test substance by gavage (5 mL/kg bw) from gestation day 6 to 27. Individual doses based on individual body weights determined on gestation day 6.

Dose formulation
Technical glyphosate was suspended in 1% aqueous Methocel® using a tissue homogenizer. The dose solutions were prepared daily.

Clinical observations
A check for mortality or overt changes in appearance and behaviour was made once daily prior to treatment. During the treatment and post-treatment period all rabbits were observed once daily for clinical signs of toxicity and mortality.

Body weight
Individual body weights of dams were recorded on gestation days 0, 6, 12, 18, 24 and 28.

Sacrifice and pathology
Dams
All surviving rabbits were sacrificed at scheduled termination on gestation day 28 by injection of an overdose of sodium pentobarbital. The number and location of viable foetuses, early and late resorptions, the number of total implantations and corpora lutea were recorded. The abdominal and thoracic cavities and organs were examined for gross pathological changes.
Rabbits that died during the study were necropsied to determine the cause of death.

Foetuses

Foetuses were not examined in this pilot study.

II. RESULTS AND DISCUSSION

A. MORTALITY

There was an increased incidence of mortalities from 500 mg/kg bw/day onwards.

Table 5.6.2-61: Glyphosate technical Pilot teratology study in the rabbit ([redacted], 1980): Mortalities

	Dose level in mg/kg bw/day					
	0	**125**	**250**	**500**	**1250**	**2500**
Spontaneous deaths*	0/5	0/5	0/5	4/5	5/5	5/5
Time of death (gestation day)	--	--	--	15-22	10, 11	9,10
% Mortality	0.0	0	0	80	100	100
Sacrificed after abortion	0	0	0	1**	0	0

* deceased animals / total animals in group
** sacrificed on gestation day 26

B. CLINICAL OBSERVATIONS

There were no biologically meaningful differences in appearance or behaviour attributable to treatment with the test item at 125 and 250 mg/kg bw/day when compared to the control. One rabbit at 125 mg/kg bw/day was noted to have a mass in the thoracic area. At necropsy this mass was found to be an abscess. Since similar conditions were not found in any other group, this abscess was considered not test item-related.

One rabbit at 500 mg/kg bw/day group aborted. The four remaining rabbits in this group and all rabbits at 1250 and 2500 mg/kg bw/day died.

C. BODY WEIGHT

There were no biologically meaningful differences in mean maternal body weight gains at 125 and 250 mg/kg bw/day when compared to the control. A severs body weight loss was noted at 500 mg/kg bw/day and higher.

Table 5.6.2-62: Glyphosate technical: Pilot teratology study in the rabbit ([redacted], 1980): Mean body weight development (in g) during gestation

		Dose level in mg/kg bw/day					
		0 (Control)	**125**	**250**	**500**	**1250**	**2500**

	6	2897	2759	2855	2817	2872	2691
	12	2958	2735	2898	2627	--	--
	18	3013	2792	2926	2508	--	--
	24	3036	2886	2987	2413	--	--
	28	3012	2934	2944	--	--	--

D. PATHOLOGY

Necropsy
Yellow foci on the gall bladder were noted in one rabbit at 500 mg/kg bw/day and in one rabbit at 1250 mg/kg bw/day. Erosions of the stomach mucosa were noted in two rabbits at 500 mg/kg bw/day and in one rabbit at 1250 mg/kg bw/day. Erosions of the oesophagus and gall bladder were noted in one rabbit at 1250 mg/kg bw/day. Varying degrees of autolysis were noted in the other animals dying on study. One rabbit at 2500 mg/kg bw/day was found to have a perforated oesophagus at necropsy and death was attributed to an intubation error.

Observations on the ovary and uterus
There were no biologically meaningful differences in the mean number of corpora lutea, total implantations, post-implantation loss or viable foetuses at 125 and 250 mg/kg bw/day. A slight increase in the mean number of early and late resorptions and post-implantation loss was noted at 250 mg/kg bw/day, when compared to the control. No data are available for animals at 500, 1250 and 2500 mg/kg bw/day as in these groups no animals survived until scheduled necropsy.

Table 5.6.2-63: Glyphosate technical: Pilot teratology study in the rabbit ([redacted], 1980): 28–day uterine examination data

III. CONCLUSIONS

The oral administration of glyphosate acid to pregnant rabbits by gavage from gestation day 6-27 did not result in maternal toxicity at 125 and 250 mg/kg bw/day; there were no treatment-related effects on pregnancy or foetuses at these dose levels. At 500 mg/kg bw/day one animal aborted and the four remaining animals died. At 1250 and 2500 mg/kg bw/day all animals died. Accordingly, under the conditions of this study, doses from 500 mg/kg bw/day and higher clearly exceeded the maximum tolerated dose (MTD).

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the pilot dose range-finding study, the oral administration of glyphosate acid to pregnant rabbits by

gavage from gestation gay 6-27 did not result in maternal toxicity at 125 and 250 mg/kg bw/day; there were no treatment-related effects on pregnancy or developmental parameters at these dose levels. At 500 mg/kg bw/day one animal aborted and the four remaining animals died. At 1250 and 2500 mg/kg bw/day all animals died. Accordingly, under the conditions of this study, doses 500 mg/kg bw/day and higher clearly exceeded the maximum tolerated dose (MTD).

Assessment and conclusion by RMS:

1. Information on the study

Data point:	**CA 5.6.2/019**
Report author	[redacted]
Report year	1980
Report title	Technical Glyphosate: Teratology study in rabbits
Report No	401-056
Document No	Not reported
Guidelines followed in study	Not stated. (pre-guideline; satisfies in general the requirements of OECD 414 (1981), but not of OECD 414 (2018))
Deviations from current test guideline (OECD 414, 2018)	Significant mortality at the higest dose tested yielded less litters than necessary to confirm the observed lack of developmental toxicity at 350 mg/kg bw/day
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities[1,2]	No (pre-GLP study)
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Glyphosate acid was administered by gavage to groups of 16 or 17 pregnant Dutch Belted rabbits each, at doses of 75, 175 and 350 mg/kg bw/day from gestation day 6-27 (insemination = day 0). A further group of 16 animals was exposed to the vehicle (0.5 % aqueous Methocel®) to serve as control.

Individual clinical observations and body weights were recorded during the study. The animals were either killed on Day 28 of gestation, or after they had aborted during the study period. All sacrificed animals or animals found dead were subjected to a gross necropsy. The uteri were examined for number of corpora lutea, early and late resorption, and total implantations. Foetuses were weighted, sexed and examined for external malformations, as well as visceral and skeletal anomalies/abnormalities.

At 175 mg/kg bw/day, a slight increase of soft stool and diarrhoea was observed in dams. At 350 mg/kg bw/day, definite signs of maternal toxicity were observed; this toxicity was manifest as signs of soft stool and/or diarrhoea in all high dose animals at least once, nasal discharge, as well as an increase in the number of dams that died. There was no maternal toxicity attributable to the administration of 75 mg/kg bw/day. In addition, there were no signs of developmental effects noted in any dose group.

The oral administration of glyphosate acid to pregnant rabbits by gavage from gestation day 6-27 resulted

in maternal toxicity at 175 and 350 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level that could not be attributed to maternal toxicity.

I. MATERIALS AND METHODS

	Humidity: controlled, but exact values not reported
	Air changes: Exact values not reported
	Light controlled

B. STUDY DESIGN

In life dates: 1979-04-10 to 1979-05-11

Animal assignment and treatment:
Sixty-four female Dutch Belted rabbits were artificially inseminated and randomly assigned to treatment groups of 16 animals. The day of insemination was designated day 0 of gestation. The rabbits received daily doses of 0, 75, 175 or 350 mg/kg bw/day test substance by gavage (1 mL/kg bw) from gestation day 6 to 27. Individual doses based on individual body weights determined on gestation day 6.

Dose formulation
For each dose level an appropriate amount of grounded technical glyphosate was suspended in 0.5 % aqueous Methocel® solution and homogenised. The dose solutions were prepared daily.

Clinical observations
A check for mortality or behavioural changes was made once daily prior to treatment. During the treatment and post-treatment period all rabbits were observed once daily for clinical signs of toxicity, mortality or behavioural changes.

Body weight
Individual body weights of dams were recorded on gestation days 0, 6, 12, 18, 24 and 28. These time points for body weight determination differ from the requirements of the current OECD guideline 414 (2001) (i.e., body weights should be determined on gestation day 0 and at 3–day intervals thereafter). Although the time-intervals were longer than required, the time points for body weight determination are considered to be sufficient to evaluate the body weight development of the pregnant animals.

Sacrifice and pathology
Dams
All surviving rabbits were sacrificed at scheduled termination on day 28. The uterus was excised and weight and the foetuses were removed. The number and location of viable foetuses, early and late resorptions, the number of total implantations and *corpora lutea* were recorded. The abdominal and thoracic cavities and organs were examined for gross pathological changes.
Rabbits that died during the study were necropsied to determine the cause of death.

Foetuses
All foetuses were weighed, sexed and examined for external malformation and variations, as well as for visceral malformations and variations. The carcasses were then fixed in alcohol, macerated in potassium hydroxide and stained with Alizarin Red S for skeletal examination.

Statistics
All statistical analyses compared the treatment groups to the control group with a level of significance at p <0.05. Foetal sex distribution and number of litters with malformations were analysed using the Chi-square test with Yates correction and/or Fisher's exact probability test. Ther number of early and late resorption and post-implantation losses were compared by the Mann-Whitney U-test.
Mean numbers of viable foetuses, total implantations, *corpora lutea* and mean foetal body weights were compared by ANOVA (one-way), Bartlett´s test for homogeneity and appropriate t-test.

II. RESULTS AND DISCUSSION

A. MORTALITY
There was an increased incidence of mortalities in the high dose group (see table below).

Table 5.6.2-64: Glyphosate technical: Teratology study in the rabbit ([redacted], 1980): Mortalities

	Control (0 mg/kg bw/day)	Low (75 mg/kg bw/day)	Intermediate (175 mg/kg bw/day)	High (350 mg/kg bw/day)
Spontaneous deaths*	0/16	1/16	2/16	10/17
Time of death (gestation day)	--	26	22, 25	3 to 21
% mortality	0.0	6.3	12.5	58.8
Sacrificed after abortion	2	0	1	1
Sacrificed on gestation day	22	--	27	23

* dead animals / total animals in group

For five of the rabbits that died spontaneously, the cause of death was attributed to pneumonia, respiratory disease, enteritis or gastroenteritis. For one rabbit of the mid-dose group and the other 7 rabbits of the high dose group, the cause of death could not be determined.
The mortality rates in the intermediate- and especially in the high-dose groups were greater than 10 %, which exceeds the OECD guideline 414 (2001) suggestion of no more than approximately 10 % maternal mortality.

D. CLINICAL OBSERVATIONS
Clinical signs consisting of soft stool and diarrhea were noted in all dose groups during the treatment period. In the 175 mg/kg bw/day dose group, the incidence of this finding was slightly increased when compared with the control group. At 350 mg/kg bw/day, either soft stool, diarrhea or both were observed in each animal at least once during the treatment period. Also in the high dose group, there was an increased incidence of animals with nasal discharge in comparison with the control group.

E. BODY WEIGHT
There were no treatment-related effects on maternal body weights and body weight gain.

Table 5.6.2-65: Glyphosate technical: Teratology study in the rabbit ([redacted], 1980): Mean body weight development (in g) during gestation (mean ± SD)

		Dose level in mg/kg bw/day			
		0 (Control)	75	175	350
Day of gestation	0	2958 ± 146.6	2876 ± 176.3	2983 ± 157.5	2834 ± 196.9
	6	2988 ± 177.5	2937 ± 187.0	3012 ± 206.9	2875 ± 232.1
	12	3039 ± 165.6	2986 ± 191.5	3029 ± 216.1	2732 ± 330.5
	18	3072 ± 166.4	3002 ± 213.4	2959 ± 276.6	2827 ± 317.2
	24	3038 ± 182.3	3005 ± 219.9	2914 ± 321.2	2999 ± 315.1
	28	3030 ± 231.7	3008 ± 142.7	2958 ± 307.5	2948 ± 238.7

F. PATHOLOGY
Necropsy
There were no macroscopic findings in dams that were considered to be related to the administration of glyphosate technical.

Observations on the ovary and uterus
No treatment-related effects were evident in the study.

Table 5.6.2-66: Glyphosate technical: Teratology study in the rabbit ([redacted], 1980): 28–day uterine examination data

	Control (0 mg/kg bw/day)	Low (75 mg/kg bw/day)	Intermediate (175 mg/kg bw/day)	High (350 mg/kg bw/day)

Non-pregnant rabbits	2/14	0/15	2/13	0/6
Abortions	2/16	0/16	1/16	1/17

* number of surviving animals / total animals in group

G. DEVELOPMENTAL PARAMETERS

There were no statistically significant differences in the mean numbers of early or late resorptions, total implantations, corpora lutea, foetal body weights or foetal sex ratio in any of the test substance groups when compared to control. The number of viable foetuses was slightly, but statistically significantly, increased in the low-dose group at 75 mg/kg bw/day. However, this finding was considered incidental and not related to the test substance.

The mean foetal body weights were slightly decreased in the test substance groups as compared to control. However, the mean foetal body weights in all test substance groups were comparable to the historical control data (i.e. 30.9 g) (see table below).

Table 5.6.2-67: Glyphosate technical: Teratology study in the rabbit ([redacted], 1980): 28–day uterine examination data

	Historical control	Control (0 mg/kg bw/day)	Low (75 mg/kg bw/day)	Intermediate (175 mg/kg bw/day)	High (350 mg/kg bw/day)
Pregnant dams[#]	24	12	15	11	6
Viable foetuses/dam	6.7	5.3 ± 2.73	7.6* ± 1.84	5.9 ± 2.77	6.3 ± 2.25
Post implantation loss/dam[##]	0.8	0.7 ± 0.89	0.4 ± 0.63	0.2 ± 0.40	0.8 ± 1.33
Total implantations /dam[##]	7.5	5.9 ± 2.39	8.0 ± 1.81	6.1 ± 2.84	7.2 ± 2.93
Corpora lutea/dam[##]	10.1	9.0 ± 2.13	10.1 ± 1.64	10.5 ± 3.45	8.5 ± 1.87
Foetal sex distribution (males/females)[#]	83/77	28/35	53/61	32/33	17/21
Mean foetal body weight (g)[##]	30.9	33.4 ± 7.27	30.9 ± 4.43	29.9 ± 7.21	29.3 ± 4.82

[#] Total number at caesarean section
[##] Number ± SD; historical control without SD
* Statistically significant difference compared to control ($p \leq 0.05$)

It should be noted that, in all dose groups, the number of pregnant dams were less than the number of pregnant dams required by the current OECD guideline 414 (2001); i.e., 16. Therefore, the evaluation of the developmental parameters may be limited.

Skeletal and visceral examination

The percentages of foetuses with skeletal malformations were 0.0, 2.6, 3.1 and 5.3 in the control, 75, 175 and 350 mg/kg bw/day groups, respectively. Although malformations were observed in the test substance groups, neither the type nor incidence of the malformations provided evidence for an adverse effect of glyphosate acid. There were no visceral malformations observed in any of the dose groups including control. There were no statistically significance differences in the variation observed in the test substance group when compared to the control group (see table below).

Table 5.6.2-68: Glyphosate technical: Teratology study in the rabbit ([redacted], 1980): Summary of foetal malformations and variations

	Hist. contr.	Control (0 mg/kg bw/day)		Low (75 mg/kg bw/day)		Intermediate (175 mg/kg bw/day)		High (350 mg/kg bw/day)

III. CONCLUSIONS

The oral administration of glyphosate acid to pregnant rabbits by gavage from gestation gay 6-27 resulted maternal toxicity at ≥175 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level that could not be attributed to maternal toxicity. Therefore the NOAEL was considered to be 75 mg/kg bw/day for maternal toxicity. The NOAEL for developmental toxicity was considered to be 350 mg/kg bw/day.

I. Assessment and conclusion

<u>Assessment and conclusion by applicant</u>:

The study was performed before GLP and the respective OECD test guidelines were established. Nevertheless, the study is generally in concordance with the current OECD 414 with the restriction that the group sizes are smaller than requested in this guideline. Therefore, the outcome can be reported as valid.

The oral administration of glyphosate acid to time-mated rabbits by gavage from gestation day 6 to 27 resulted in maternal toxicity at ≥175 mg/kg bw/day. There were no treatment-related effects on pregnancy or foetuses at any dose level that could not be attributed to maternal toxicity. Therefore, the

NOAEL was considered to be 75 mg/kg bw/day for maternal toxicity. The NOAEL for developmental toxicity was considered to be 175 mg/kg bw/day because of the high dose offspring NOAEL of 350 mg/kg bw/day could not be relied upon because maternal mortality resulted in only six litters for six surviving dams.

Assessment and conclusion by RMS:

CA 5.7 Neurotoxicity

There was no evidence of neurotoxicity in acute, subchronic or chronic studies in rodents and dogs. An acute neurotoxicity in rats was performed by [redacted] (CA 5.7.1-001) and is considered acceptable in accordance to the conclusion from RAR (2015). A single administration of glyphosate acid produced clinical signs of toxicity (including decreased activity, subdued behaviour, hunched posture, sides pinched in, tip-toe gait and/or hypothermia) at approximately 6 hours after dosing on day 1 in 3/10 females, only, which received 2000 mg/kg bw. One of these females was subsequently found dead on day 2. These clinical signs were considered to reflect general toxicity associated with the administration of high dose levels of glyphosate acid. Quantitative assessment of landing foot splay, sensory perception, muscle weakness and locomotor activity revealed no changes indicative of neurotoxic potential. Histopathological evaluation of the central and peripheral nervous system revealed no treatment-related changes in animals receiving 2000 mg/kg. The no-observed effect level (NOEL) for neurotoxicity, following single oral administration of glyphosate acid was 2000 mg/kg bw.

In addition to the acute study two sub-chronic neurotoxicity studies were also performed ([redacted], 2006, CA 5.7.1/002 and [redacted], 1996, CA 5.7.1/003). The study by [redacted] has not been evaluated at EU level so far and is considered valid. Similarly, the study from [redacted] (1996) is considered acceptable in accordance to the conclusion from RAR (2015). In the [redacted] (2006) study rats were fed glyphosate up to 20000 ppm for 90 consecutive days. Administration of glyphosate produced no unscheduled deaths and no clinically observable signs of systemic toxicity or neurotoxicity. No treatment-related effects were detected in behavioural assessment, functional performance tests, sensory reactivity, or ophthalmoscopy examinations. No adverse effect on bodyweight changed, dietary intake or food efficiency or water consumption were detected. In addition, there were no treatment-related changes in brain weight. No macroscopic changes or neuropathological changes within a comprehensive histopathological evaluation were detected which could be attributed to administration of glyphosate. In conclusion, no evidence of a neurotoxic potential was obtained up to the highest dose of 20000 ppm. Therefore, the no observed adverse effect level (NOAEL) for neurotoxic potential, following dietary administration of glyphosate for at least 90 days, was 20000 ppm (equivalent to 1499 and 1555 mg/kg bw/day for males and females, respectively).

In the study from [redacted] (1996, CA 5.7.1/003) administration of glyphosate acid to rats at up to 20000 ppm for 90 consecutive days produced no clinical signs of toxicity or effects on any of the quantitative functional observation battery tests or on locomotor activity that indicated any neurotoxic potential. In addition, there were no treatment-related changes in brain weight, length or width. Comprehensive histopathological evaluation of the peripheral and central nervous system revealed no evidence of any changes which could be attributed to administration of glyphosate acid. The no observed effect level (NOEL) for neurotoxic potential, following dietary administration of glyphosate acid for at least 90 days, was 20000 ppm (equivalent to 1547/1631 mg/kg bw/day in males and females respectively). There was a treatment-related effect on growth and food utilisation in males receiving 20000 ppm (1547 mg/kg bw/day). In this study the NOEL for systemic toxicity was 8000 ppm (617 mg/kg bw/day) in males and 20000 ppm (1631 mg/kg bw/day) in females.

Glyphosate is often erroneously called an organophosphate pesticide. However, it is important to note that glyphosate is not an organophosphate ester but a phosphonoglycine, a chemical class that does not inhibit cholinesterase activity. Therefore, studies for delayed neurotoxicity are not considered essential. Despite

this, two studies for delayed neurotoxicity in hens ([redacted], 1996 and [redacted], 1987) have been conducted. The study by [redacted] (1987) is found not acceptable by today's standards in accordance with the evaluation in the RAR (2015). Therefore, this study is not used for risk assessment. The study by [redacted] (1996) is considered acceptable in accordance with the evaluation in the RAR (2015). Administration of a single dose of glyphosate acid to hens at a level of 2000 mg/kg bw and an observation for the following 21/22 days revealed no clinical signs of delayed locomotor ataxia. There was no histological evidence of acute delayed neurotoxicity, and there were no significant reductions in neuropathy target esterase levels in the brain and spinal cord. Therefore, the NOAEL for acute delayed neurotoxicity, following single oral administration of glyphosate acid was 2000 mg/kg bw.

In a study performed by [redacted] (1996, see CA 5.8.2) *ex vivo* investigations with isolated rat gastrocnemius muscle were performed. Evaluation of innervated muscle response showed that glyphosate technical, when administered at the maximum solubility concentration in physiological saline (12 mg/mL), did not cause any neuromuscular blocking activity.

Overall, across a wide database of acute and subacute neurotoxicity and repeated dose studies there is no evidence that glyphosate has specific neurotoxic or delayed neurotoxicity potential.

During the literature search the following publications were considered relevant with regards to neurotoxicity:

Martinez et al. (2019) investigated the effect of acute exposure to glyphosate (GPH) on the blood-brain barrier in vitro based on induced pluripotent stem cells (iPSCs) and compared to two chemical analogues: aminomethylphosphonic acid (AMPA) and glycine (GLY), for concentrations ranging from 0.1 µM to 1000 µM. The data from this study demonstrate the relative safety of glyphosate and AMPA with regard to the blood-brain barrier after acute exposure with minimal effects observed at concentrations significantly higher than baseline exposure levels, occupational and non-occupational alike. The presence of an active uptake and passage of glyphosate across the blood-brain barrier suggests the need for extensive brain-centred studies to evaluate the pharmacokinetics and pharmacodynamics of glyphosate on the central nervous system during acute exposure and in individuals exposed to high amounts of such pesticides.

Martinez et al. (2018) examined the effects of glyphosate oral exposure (35, 75, 150 and 800 mg/kg bw, 6 days) on brain region monoamine levels of male Wistar rats. The results demonstrate that glyphosate leads to lower concentrations of 5-HT, DA and NE levels in the CNS. The effects observed in the present study indicates a potential of glyphosate to lower neurotransmitter concentrations in brain regions of Wistar rats. The authors concluded that although no data on humans are available, glyphosate could exert its neurotoxicity, notably on monoamine systems. Further work is needed to investigate glyphosate herbicide and potential links with neurodegenerative diseases. In the study from Martinez no additional investigations related to neurotoxicity were performed on rats during the treatment phase. The study from Martinez (2019) is regarded as an indicator study for neurotoxicity based on the endpoints addressed. Indications of neurotoxicity have not been identified in the available guideline studies focussing on neurotoxic effects (see CA 5.7.1/001 to CA 5.7.2/002).

Chorfa et al. (2013) studied the effects of four pesticides (paraquat, rotenone, maneb and glyphosate) on different molecular events in cell lines which are considered to be related to Parkinson`s disease. Three of the four pesticides triggered molecular events involved in Parkinson`s disease. However, glyphosate was not active in this study.

Table 5.7-1: Studies on neurotoxicity with glyphosate

CA 5.7.1 Neurotoxicity studies in rodents

Acute neurotoxicity

1. Information on the study

Data point:	CA 5.7.1/001
Report author	[redacted]
Report year	1996
Report title	Glyphosate acid: Acute neurotoxicity study in rats
Report No	[redacted]/P/4866
Document No	Not reported
Guidelines followed in study	No guideline stated in the report but in general compliance with OECD 424 (1997)
Deviations from current test guideline	None
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Groups of 10 animals Alpk:APfSD rats per sex were administered single oral doses of 0, 500, 1000 or 2000 mg/kg bw glyphosate acid. All animals were observed daily for any changes in clinical condition for two weeks post administration. Detailed clinical observations including quantitative assessments of foot landing

splay, sensory perception and muscle weakness were performed at weekly intervals. At scheduled termination 5 rats/sex/group were subjected to full *post mortem* examination. Selected nervous system tissues were examined microscopically.

Clinical signs of toxicity (including decreased activity, subdued behaviour, hunched posture, sides pinched in, tip-toe gait and/or hypothermia) occurred during Day 1 but were limited to 3 females at approximately 6 hours post treatment, in the highest dose group (2000 mg/kg/day). One of these females was subsequently found dead on Day 2.

Slight reductions in food consumption, without any associated effects on body weight, were also observed during Week 1 for both sexes in the highest dose group.

Quantitative assessment of neurotoxic parameters and histopathological evaluation of the central and peripheral nervous system confirmed no neurotoxic potential for glyphosate.

In conclusion, there was no evidence of specific neurotoxicity up to the highest dose tested (2000 mg/kg bw). Therefore, the no observed effect level (NOEL) for neurotoxicity, following single oral administration of glyphosate acid, was 2000 mg/kg bw.

2. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	Glyphosate acid
Description:	White solid
Lot/Batch #:	P24 ([redacted] reference number: Y04707/034)
Purity:	95.6 % w/w
Stability of test compound:	The test substance was shown to be stable for the period of use.

2. Vehicle and/or positive control: Deionised water

3. Test animals:

Species:	Rats
Strain:	Alpk:AP$_f$SD (Wistar-derived)
Source:	[redacted]
Age:	At least 28 days
Sex:	Males and females
Weight at dosing:	♂ 171.4 – 175.0 g; ♀ 144.6 – 148.7 g
Acclimation period:	Approx. 2 weeks
Diet/Food:	CT1 diet (Special Diets Services Limited, Stepfield, Witham, Essex, UK), *ad libitum,* except 24 h prior dosing
Water:	Tap water, *ad libitum*
Housing:	In groups of five, separated by sex, in multiple rats racks.
Environmental conditions:	Temperature: 19 – 23°C Humidity: 40 – 70 % Air changes: 25 – 30/hour I. ours light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: Not reported. The study was conducted during May and June 1995.

Animal assignment and treatment

In an acute neurotoxicity study groups of ten male and ten female Alpk:APfSD (Wistar derived) rats were administered with a single oral dose of 0, 500, 1000 or 2000 mg/kg bw glyphosate acid by gavage.

Dosing Formulation Analysis

Verification of the achieved concentrations was done with samples of each preparation. Homogeneity was determined with samples from the low to high dose levels. The chemical stability of glyphosate acid in water was also determined for all dose formulations over a period of 10 days.

Clinical observations

Clinical observations were made prior to administration and daily thereafter. Any abnormalities together with the observation of no abnormality detected were recorded**.**

Body weight

The body weight of each rat was recorded on Days -7 and -1, immediately before dosing (Day 1), approximately 6 hours after dosing (Day 1) and on Days 8 and 15.

Food consumption

Food consumption for each cage of rats was recorded throughout the study and calculated on a weekly basis**.**

Functional Observational Battery

Prior to the start of treatment (Week -1) and on Day 1, 8 and 15, all animals were observed for signs of functional/behavioural toxicity with quantitative assessment of landing foot splay, sensory perception (tail-flick test) and muscle weakness (fore- and hindlimb grip strength). Detailed clinical assessments and functional performance tests were performed together with an assessment of sensory reactivity to different stimuli. Those included but were not limited to the following list of measures: assessment of autonomic function (e.g. lachrymation, salivation, piloerection, exophthalmus, urination, defecation, pupillary function, ptosis); description, incidence and severity of any convulsions, tremors, abnormal motor function, abnormal behaviour; reactivity to stimuli; changes in level of arousal; sensorimotor responses; alterations in respiration. Locomotor activity was also assessed at these time points. Each observation period was divided into ten scans of five minute duration. Treatment groups were counter balanced across test times and across devices and when the trials were repeated each animal was returned to the same activity monitor at approximately the same time of day. Motor activity was assessed in a separate room to minimise disturbances.

Sacrifice and pathology

At scheduled termination, 5 rats/sex/group designated for neuropathology were sacrificed. Brain weight, brain length and brain width were determined. The following tissues were submitted: brain, spinal cord (cervical and lumbar), Gasserian ganglion, dorsal root ganglia and spinal roots (cervical and lumbar), gastrocnemius muscle, sciatic nerve, sural nerve and tibial nerve.
Submitted tissues were processed as follows: brain (seven levels including the cerebral cortex, the hippocampus, the cerebellum, the pons and medulla), dorsal root ganglia and spinal roots from cervical and

lumbar regions of the cord after decalcification, and gastrocnemius muscle from rats receiving either 0 (control) or 2000 mg/kg bw glyphosate acid were routinely processed, paraffin wax embedded and 5µm thick sections were cut and then stained with haematoxylin and eosin. Sections of brain and cord were in the transverse plane.

The Gasserian ganglion, sciatic nerve, spinal cord (cervical and lumbar portions), sural and tibial nerve from control and high dose group rats were processed and then embedded in Araldite. Semi-thin sections were cut and then stained with toluidine blue. For bilateral tissues only the left was processed. All tissues were sectioned in the transverse plane except the sciatic nerve which was sectioned in both the transverse and the longitudinal plane.

Neuropathological examination was performed on control and highest dose group animals only. All sections were examined by light microscopy.

Statistics

Analyses of variance and covariance were carried out using the GLM procedure in SAS (1989). Least-squares means for each group were calculated using LSMEAN option in SAS PROC GLM. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squared mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a two-sided Student's t-test, based on the error mean square in the analysis.

The levels of probability chosen as significant different from control were $p < 0.01$** and $p < 0.05$* (Student's t-test, two-sided).

II. RESULTS

A. DOSING FORMULATION ANALYSIS

The achieved concentrations of glyphosate acid in water were within 3 % of the nominal levels. The homogeneity was considered acceptable, with a deviation from the overall mean values of approximately ± 8 %. The chemical stability was considered satisfactory.

B. MORTALITY AND CLINICAL OBSERVATIONS

Two females receiving 2000 mg/kg bw glyphosate acid showed subdued behaviour, decreased activity, hunched posture, sides pinched in, tip-toe gait and hypothermia on the day of administration. One of these animals died on the subsequent day. The other one together with an additional female which showed diarrhoea on the day of administration regained full recovery the subsequent day. One female receiving 500 mg/kg bw, was found dead approximately 6 h after administration.
In the absence of any treatment-related clinical signs prior to death, and because no deaths were observed at the intermediate dose level of 1000 mg/kg bw, the death of this animal was considered not to be treatment related.
Distension of the abdomen was recorded for several males from all treated groups on the day of administration. However, in the absence of any dose relationship, this was not considered to be treatment-related.

C. BODY WEIGHT

No treatment-related effects were observed.

D. FOOD CONSUMPTION

During Week 1, mean food consumption was lower in animals receiving 2000 mg/kg bw glyphosate acid compared to controls, although the difference did attain statistical significance only in females (see **Table 5.7.1-1**). There was no evidence of treatment-related effects in animals receiving 500 or 1000 mg/kg bw.

Table 5.7.1-1: Glyphosate acid: Acute neurotoxicity study in rats ([redacted], 1996): Intergroup comparison of food consumption (g/rat/day) during Week 1

Dose level of glyphosate (mg/kg bw)			
0 (control) **Mean ± SD**	**500** **Mean ± SD**	**1000** **Mean ± SD**	**2000** **Mean ± SD**
Males			
29.9 ± 0.7	29.0 ± 0.1	30.1 ± 0.4	28.4 ± 0.2
Females			
22.4 ± 1.0	22.2 ± 0.2	22.8 ± 0.3	20.6* ± 0.3

* Statistically significant difference from the control group mean at the 5 % level (Student's t-test, two-sided)

E. FUNCTIONAL OBSERVATIONAL BATTERY

Examinations of the functional observational battery did not identify any conclusive treatment- and dose-related effects.

Group mean landing foot splay for males receiving 2000 mg/kg bw was statistically significantly lower than that of concurrent controls at approximately 6 hours after dosing on day 1. However, as pre-experimental values for these animals were low, in comparison with control pre-experimental values, the apparent reduction in landing foot splay for high dose group animals on day 1 was considered not to be attributable to administration of glyphosate acid. Group mean landing foot splay for females receiving 500 mg/kg bw was slightly higher than that of concurrent controls on day 15. However, in isolation, this finding was considered to be unrelated to administration of glyphosate acid.

Table 5.7.1-2 Glyphosate acid: Acute neurotoxicity study in rats ([redacted], 1996): Intergroup comparison of landing foot splay (mm)

Dose level of glyphosate (mg/kg bw)				
	0 (control) **Mean ± SD**	**500** **Mean ± SD**	**1000** **Mean ± SD**	**2000** **Mean ± SD**
Males				
Day -7	50.1 ± 7.3	47.7 ± 7.1	51.6 ±6.2	38.9 ± 5.6
Day 1	54.9 ± 7.6	50.0 ± 7.8	56.8 ± 7.8	45.6* ± 6.8
Day8	58.9 ± 8.1	57.3 ± 10.6	58.5 ± 12.1	54.9 ± 3.6
Day 15	62.3 ± 7.6	64.6 ± 6.9	67.9 ± 13.2	59.3 ± 7.3
Females				
Day -7	42.4 ± 7.1	46.6 ± 9.2	38.7 ± 5.1	48.6 ± 8.6
Day 1	47.8 ± 8.1	48.4 ± 7.3	47.5 ± 7.8	51.7 ± 8.4
Day8	51.2 ± 8.0	58.1 ± 9.9	54.7 ± 12.0	56.9 ± 8.9
Day 15	54.1 ± 9.1	64.0* ± 9.8	58.6 ± 10.3	56.8 ± 6.7

* Statistically significant difference from the control group mean at the 5 % level (Student's t-test, two-sided)

Group mean time to tail flick for males receiving 500 mg/kg bw was slightly higher than that of concurrent controls on day 15. However, in isolation, this finding was considered to be unrelated to administration of glyphosate acid.

Table 5.7.1-3 Glyphosate acid: Acute neurotoxicity study in rats ([redacted], 1996): Intergroup comparison of time to tail flick (s) in male rats

Dose level of glyphosate (mg/kg bw)				
	0 (control) Mean ± SD	**500 Mean ± SD**	**1000 Mean ± SD**	**2000 Mean ± SD**
Day -7	8.1 ± 2.9	7.5 ± 2.5	6.0 ± 2.2	7.5 ± 3.7
Day 1	6.3 ± 1.9	6.5 ± 2.6	5.2 ± 2.4	7.5 ± 2.1
Day8	5.3 ± 2.9	5.8 ± 1.9	6.0 ± 2.2	6.1 ± 1.7
Day 15	7.6 ± 3.1	10.9* ± 4.3	6.7 ± 1.9	6.6 ± 2.2

* Statistically significant difference from the control group mean at the 5 % level (Student's t-test, two-sided)

Group mean forelimb grip strength for males receiving 500 mg/kg bw was slightly higher than that of concurrent controls on day 15. However, in isolation, this finding was considered to be unrelated to administration of glyphosate acid.

Table 5.7.1-4 Glyphosate acid: Acute neurotoxicity study in rats ([redacted], 1996): Intergroup comparison of forelimb grip strength (g) in male rats

Dose level of glyphosate (mg/kg bw)				
	0 (control) Mean ± SD	**500 Mean ± SD**	**1000 Mean ± SD**	**2000 Mean ± SD**
Day -7	520 ± 69	538 ± 68	520 ± 89	488 ± 66
Day 1	733 ± 139	705 ± 117	723 ± 99	728 ± 122
Day8	775± 153	798 ±161	850 ± 135	775 ± 129
Day 15	858 ± 175	1015* ± 193	915 ± 147	823 ± 93

* Statistically significant difference from the control group mean at the 5 % level (Student's t-test, two-sided)

Mean overall motor activity values were slightly lower than those of concurrent controls for males and females which received 2000 mg/kg bw on day 1. However, these differences did not attain statistical significance and were considered too small to be of toxicological importance. Mean overall motor activity values were also slightly lower than those of concurrent controls for males which received 2000 mg/kg bw on day 15. However, in the absence of any treatment-related effects for these animals on day 8, this was considered to be incidental and unrelated to administration of glyphosate acid.

Table 5.7.1-5 Glyphosate acid: Acute neurotoxicity study in rats ([redacted], 1996): Intergroup comparison of motor activity (Overall: minutes 1-50)

Dose level of glyphosate (mg/kg bw)				
	0 (control) Mean ± SD	**500 Mean ± SD**	**1000 Mean ± SD**	**2000 Mean ± SD**
Males

* Statistically significant difference from the control group mean at the 5 % level (Student's t-test, two-sided)

F. PATHOLOGY

Necropsy

No macroscopic findings were detected.

Histopathology

No microscopic findings were considered to be treatment-related.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable. There was no evidence of specific neurotoxicity up the highest single dose of 2000 mg/kg bw. Based on the study results the NOEL for acute neurotoxicity, following single oral administration of glyphosate acid, is 2000 mg/kg bw.

Assessment and conclusion by RMS:

Subchronic neurotoxicity

1. Information on the study

Data point:	CA 5.7.1/002
Report author	[redacted]
Report year	2006
Report title	Ninety Day Repeated Dose Oral (Dietary) Neurotoxicity Study in the Rat
Report No	2060-0010
Document No	NA
Guidelines followed in study	OECD 424 (1997)
Deviations from current test guideline	None
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

In a subchronic neurotoxicity study, groups of 10 male and 10 female Sprague-Dawley (Crl:CD® (SD) IGS BR) rats were fed diets containing 0, 1000, 5000 or 20000 ppm glyphosate (equivalent to a mean achieved

dosage of 0, 77, 395, or 1499 mg glyphosate /kg bw/day in males and 0, 78, 404, or 1555 mg glyphosate /kg bw/day in females for 90 consecutive days.

Clinical signs, functional observations, bodyweight development and food and water consumption were monitored during the study. Ophthalmoscopic examination was also performed on control group and high dose animals before the start of treatment and during the final week of treatment. Five animals per sex from each dose group were subjected to whole body perfusion with glutaraldehyde: paraformaldehyde, followed by the recording of brain weight. Histopathological examinations of neural tissue were performed on all perfused animals from the high dose and control group animals.

Administration of glyphosate produced no unscheduled deaths and no clinically observable signs of systemic toxicity or neurotoxicity. No treatment-related effects were detected in behavioural assessment, functional performance tests, sensory reactivity, or ophthalmoscopy examinations. No adverse effect on bodyweight changed, dietary intake or food efficiency or water consumption were detected. In addition, there were no treatment-related changes in brain weight. No macroscopic changes or neuropathological changes within a comprehensive histopathological evaluation were detected which could be attributed to administration of glyphosate.

In conclusion, no evidence of a neurotoxic potential was obtained up to the highest dose of 20000 ppm. Therefore, the no observed adverse effect level (NOAEL) for neurotoxic potential, following dietary administration of glyphosate for at least 90 days, was 20000 ppm. (equivalent to 1499 and 1555 mg/kg bw/day for males and females, respectively).

Weight at dosing:	♂ 115 – 153 g (mean); ♀ 118 – 151 g (mean)
Acclimation period:	Up to 7 days
Diet/Food:	Rodent PMI 5002 (certified) diet (BCM IPS Limited, London, UK) and Rodent Rat and Mouse SQC Ground Diet No. 1 (Special Diets Services Limited, Witham, Essex, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Four per cage per sex in polypropylene grid-floor cages suspended over trays lined with absorbent paper

Environmental conditions:	Temperature:	19-23°C
	Humidity:	40-70 %
	Air changes:	at least 15 / hour
	Photoperiod:	12 hours light/dark cycle

B: STUDY DESIGN AND METHODS

In life dates: August 2005 to February 2006

Animal assignment and treatment

In a subchronic neurotoxicity study, groups of 10 male and 10 female Sprague-Dawley rats were fed diets containing 0, 1000, 5000 or 20000 ppm glyphosate for 90 consecutive days (equivalent to mean achieved dose levels of 0, 77, 395 or 1499 mg/kg bw/day for males, and 0, 78, 404 or 1555 mg/kg bw/day for females).

Dietary admixtures were prepared prior to treatment and then twice during the three month study period (i.e. at approximately monthly intervals). The diet was stored at ambient conditions in labelled, double black plastic bags in labelled, covered plastic bins when not in use.

Prior to the start of treatment, the suitability of the formulation procedure was confirmed by measurement of achieved concentration and homogeneity at concentrations of 20000, 5000 and 500 ppm. Samples were taken of each dietary admixture and were analysed for homogeneity, stability and concentration. The concentration of glyphosate technical in the dietary admixtures was determined by high performance liquid chromatography (HPLC) using an external standard technique.

Mortality/Morbidity

All animals were observed twice daily, early and late during the working day, for morbidity and mortality.

Clinical observations

All animals were examined for overt signs of toxicity, ill-health or behavioural change once daily. All observations were recorded.

Functional observational battery (FOB)

Prior to the start of treatment and during Weeks 3, 5, 9 and 13, all animals were observed for signs of functional/behavioural toxicity. Functional performance tests were also performed together with an assessment of sensory reactivity to different stimuli. Observations were carried out at a similar time on each occasion wherever possible. The minor deviations that occurred were considered not to have affected the purpose or integrity of the results obtained. Detailed individual clinical observations were performed for each animal using a purpose built arena. The following parameters were observed: gait, posture, tremors, twitches, convulsions, bizarre/abnormal/stereotypic behaviour, salivation, pilo-erection, exophthalmia, lachrymation, hyper/hypothermia, skin colour, respiration, palpebral closure, urination, defecation, transfer arousal, tail elevation. Functional performance tests were also performed together with an assessment of sensory reactivity to different stimuli. The examinations included quantitative assessments of muscle weakness (fore- and hind limb grip strength).

Locomotor activity

Locomotor activity was monitored by an automated activity recording apparatus. All animals were tested at weeks 3, 5, 9 and 13. The evaluation period was thirty minutes for each animal (with the exceptions of some females during Week 3, which were assessed for twenty-five minutes). The percentage of time each

animal was active and mobile was recorded for the overall period and also during the final 20 % of the period (considered to be the asymptotic period).

Body weight

Individual bodyweights were recorded on Day 1 (prior the start of treatment) and at weekly intervals thereafter. Bodyweights were also recorded prior to terminal kill.

Food consumption and compound intake

Food consumption was recorded for each cage group at weekly intervals throughout the study. Food utilisation was calculated retrospectively.

Water consumption

Water intake was observed daily, for each cage group, by visual inspection of the water bottles for any overt intergroup differences.

Ophthalmoscopic examination

The eyes of all control and high dose animals were examined pre-treatment and before termination of treatment (during Week 13). Examinations included observation of the anterior structures of the eye, pupillary and corneal blink reflex and, following pupil dilation with a mydriatic, detailed examination of the internal structure of the eye using a direct ophthalmoscope.

Sacrifice and pathology

On completion of the dosing period, all animals were killed by intravenous overdose of sodium pentobarbitone. Five males and five females from each dose group were then perfused with glutaraldehyde: paraformaldehyde.

Following perfusion, all animals (both perfused and non-perfused) were subjected to a gross external and internal necropsy and any macroscopic abnormalities were recorded.

The brain from all perfused animals was weighed prior to immersion in buffered 10 % formalin.

Samples of the following tissues were removed from all perfused animals and were immersed in buffered 10 % formalin for histopathology investigations:
Brain: olfactory bulb, forebrain, centre of cerebrum (including hippocampus), midbrain, cerebellum, pons and medulla oblongata
Dorsal root ganglia: (cervical and lumbar sections)
Dorsal and ventral root fibres: (longitudinal cervical and lumbar sections)
Eyes: (longitudinal sections)
Optic nerve: (longitudinal sections)
Sciatic nerve: proximal (longitudinal and transverse sections)
Tibial nerve: proximal (at the knee) and calf muscle branches - (longitudinal and transverse sections)
Skeletal (calf) muscle: (transverse sections)
Spinal cord: (longitudinal and transverse cervical and lumbar sections)

All tissues from the perfused animals from the high dose and control groups were processed to paraffin wax, sectioned, at a nominal thickness of 5 µm and stained with haematoxylin and eosin for subsequent microscopic examination.

Statistics

Data were processed to give group mean values and standard deviations where appropriate. All data were summarised in tabular form. Where appropriate, quantitative data were analysed by the Provantis™ Tables and Statistics Module. For each variable, the most suitable transformation of the data was found, the use of possible covariates checked and the homogeneity of means assessed using ANOVA or ANCOVA and Bartlett's test. The transformed data were analysed to find the lowest treatment level that showed a significant effect, using the Williams Test for parametric data or the Shirley Test for non-parametric data. If no dose response was found, but the data showed non-homogeneity of means, the data were analysed by a stepwise Dunnett (parametric) or Steel (non-parametric) test to determine significant differences from the control group. Finally, if required, pair-wise tests were performed using the Student t-test (parametric) or the Mann-Whitney U test (non-parametric).

Probability values (p) are presented as follows: $p < 0.01$ (**); $p < 0.05$ (*); $p \geq 0.05$ (not significant).

II. RESULTS

A. DOSING FORMULATION ANALYSIS

The initial dietary admixtures were within 3 % of the nominal concentration and showed the test material to be evenly dispersed with the diet matrix. Stability of the test material in the diet matrix at these concentrations, under the conditions of use during the study, was also confirmed as part of these initial investigations. Achieved concentrations following storage for six weeks were within 6 % of initial concentrations.

Achieved concentrations of dietary admixtures used on the study were measured on three separate occasions and were between 80-102 % of nominal concentration. Homogeneity was also confirmed on these occasions. These results confirmed the continuing accuracy of the formulation procedure.
These results indicate that the mean prepared dietary admixture concentrations were within acceptable limits for the purpose of the study

B. MORTALITY

There were no unscheduled deaths during the treatment period.

C. CLINICAL OBSERVATIONS

There were no neurotoxicologically significant clinical observations detected during the study or at terminal kill.

Incidents of generalised fur loss, staining of the fur and scab formation detected throughout the control and treatment groups, were considered unrelated to treatment. One female treated with 1000 ppm glyphosate displayed a kink in the tail from Day 79 onwards. This was an isolated finding and considered unrelated to treatment.

D. FUNCTIONAL OBSERVATIONS

Functional observational battery (FOB)

No treatment-related effects were detected in the parameters investigated.

All inter and intra group differences in urination, defecation and transfer arousal scores were considered to be a result of normal variation for rats of the strain and age used and were of no toxicological importance.

Sensory Reactivity Assessment

There were no treatment-related changes in the sensory reactivity parameters investigated.

All inter and intra group differences in sensory reactivity scores were considered to be a result of normal variation for rats of the strain and age used and were of no neurotoxicological importance.

Grip Strength Measurements

There were no statistically significant differences detected for mean forelimb and mean hindlimb grip strength test values for treated animals of either sex, in comparison to controls during the study period.

Motor activity

Motor activity assessments did not reveal any obvious signs of neurotoxicity.

Overall activity for females was increased at all treatment levels on Day 57 and Day 85 when compared to control values ($p < 0.01$). No such effects were evident at the previous time-points for females, and in the absence of supporting data to suggest these increases were attributed to treatment, these findings were most probably due to low control values and unrelated to treatment.

Statistically significant increases were also evident for the last 20 % activity for females treated with 5000 and 1000 ppm on Day 57, but this was not apparent at 20000 ppm. No such effects were evident on Day 85 and in the absence of a convincing dose-related response. These findings were considered to have arisen incidentally and were of no toxicological importance.

Effects for males were confined to statistically significant increases in overall activity evident for males treated with 1000 ppm on Day 15 and Day 29 ($p < 0.05$) and males treated with 5000 ppm showed a statistically significant reduction during Day 85 ($p < 0.01$). No effects were evident for males treated with 20000 ppm throughout the treatment periods, and in the absence of a dose-related response, these intergroup differences were considered to be of no toxicological significance.

E. BODY WEIGHT

A slightly inferior bodyweight gain was evident during the first two weeks of treatment for females treated with 20000 ppm ($p < 0.05$) and for males treated with 20000 ppm during the first four weeks of treatment ($p < 0.01$ - $p < 0.05$).

Males treated with 5000 ppm also showed occasional lower bodyweight gain up to Week 9. These changes also showed a dose-related response.

No effects were noted for females treated with 5000 ppm or animals of either sex treated with 1000 ppm throughout the treatment period.

F. FOOD/WATER CONSUMPTION AND COMPOUND INTAKE

Dietary intake was slightly lower than the controls during the first two weeks of treatment for males treated with 20000 ppm. Thereafter, recovery of food intake was apparent, although food consumption for males still tended to be marginally lower than controls throughout the treatment period. For females at this level, there was a suggestion of lower intake during the first two weeks of treatment, however, differences from controls were minimal and food intake thereafter was essentially similar to controls. None of these changes achieved statistical significance.

Food consumption for both sexes at 5000 and 1000 ppm were considered to have been unaffected by treatment.

13-13	29.1	30.0	28.6	27.2	18.9	18.8	20.2	18.4

There was no clear effect on food conversion efficiency at any of the dietary inclusion levels investigated, despite the initial effect observed on bodyweight gain and food consumption at 20000 ppm. This finding suggests that the initial reduced bodyweight gain and food intake at this inclusion level could be attributable to slight unpalatability of the dietary admixture.

The mean doses received for males and females respectively were 77, 395, 1499 and 78, 404, 1555 mg glyphosate /kg bw/day at dose levels of 1000, 5000 and 20000 ppm, respectively

Daily visual inspection of water bottles did not show any overt intergroup differences.

G. OPHTHALMOSCOPY

No treatment-related intergroup differences were detected.

The incidental finding recorded for one control animal (female number 11) at the pre-test observation (diffuse opacity of the right eye) was consistent with a low incidental normal finding in young rats of the strain employed and had resolved by the end of the treatment period.

H. PATHOLOGY

Brain measurements

A slight increase in brain weight, both absolute and relative to terminal bodyweights, was evident for males treated with 20000 ppm ($p < 0.05$). This was most probably a consequence of the slight reduction in bodyweight gain evident during the first weeks of treatment. All values were within the normally expected ranges for these parameters and in the absence of any histopathological correlates, these differences were considered to be of no toxicological importance.
No effect was evident for females treated with 20000 ppm or for animals of either sex treated with 5000 or 1000 ppm.

	N	5	5	5	5	5	5	5	5

[#]: numbers may slightly differ compared to the study report due to rounding.

Necropsy

No macroscopic abnormalities were detected in control or treatment group animals at terminal kill.

Histopathology

Histopathological examination of the selected tissues from animals of either sex treated with 20000 ppm did not show any treatment-related pathological changes.

Study conclusion:
Dietary administration of the test material, glyphosate technical, to rats for a period of ninety consecutive days at dietary concentrations of up to 20000 ppm did not result in any neurotoxic effects. The "No Observed Adverse Effect Level" (NOAEL) for neurotoxicity was, therefore, considered to be 20000 ppm.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable. No evidence of a neurotoxic potential was observed up to the highest dose of 20000 ppm. The no observed effect level (NOEL) for neurotoxic potential, following dietary administration of glyphosate acid for at least 90 days, was 20000 ppm, corresponding to 1499 / 1555 mg/kg bw/day for males and females, respectively.

Assessment and conclusion by RMS:

2. Full summary

In a subchronic neurotoxicity study, groups of 12 male and 12 female Alpk:APfSD (Wistar-derived) rats were fed diets containing 0, 2000, 8000 or 20000 ppm glyphosate acid for 13 weeks.

All animals were observed prior to the study start and daily throughout the study for any changes in clinical condition. In addition, detailed clinical observations, including quantitative assessments of landing foot splay, sensory perception and muscle weakness, were performed at intervals. Locomotor activity was also monitored at intervals. At the end of the study, 6 rats/sex/group were killed and subjected to a full post mortem examination. Selected nervous system tissues were removed, processed and examined microscopically.

Administration of glyphosate acid produced treatment-related effects on growth and food utilisation in males receiving 20000 ppm, with no associated effects on food consumption. There were no treatment-related effects on bodyweight, food consumption or food utilisation for males receiving 2000 or 8000 ppm, or for females from all treated groups.

There were no clinical signs of toxicity or effects on any of the quantitative functional observation battery tests or on locomotor activity that indicated any neurotoxic potential. In addition, there were no treatment-related changes in brain weight, length or width. Comprehensive histopathological evaluation of the peripheral and central nervous system showed no evidence of any changes which could be attributed to administration of glyphosate acid.

In conclusion, no evidence of a neurotoxic potential was obtained up to the highest dose of 20000 ppm. Therefore, the no observed effect level (NOEL) for neurotoxic potential, following dietary administration of glyphosate acid for at least 90 days, was 20000 ppm (equivalent to 1546.5 and 1630.6 mg/kg bw/day for males and females respectively).

I. MATERIALS AND METHODS

A: MATERIALS

1. Test material:

Identification:	Glyphosate acid (technical)
Description:	White solid
Lot/Batch #:	P24 ([redacted] reference number: Y04707/034)
Purity:	95.6 %
Stability of test compound:	Confirmed for the study period
2. Vehicle and/ or positive control:	Plain diet

3. Test animals:

Species:	Rats
Strain:	Alpk:APfSD
Source:	[redacted],

Age:	At least 6 weeks
Sex:	male and female
Weight at dosing:	♂ 215.0 – 218.6 g (mean); ♀ 173.5 – 178.8 g (mean)
Acclimation period:	Approximately 2 weeks
Diet/Food:	CT1 diet (Special Diet Services Limited, Witham, Essex, UK), *ad libitum* (except up to 24 hours prior to dosing)
Water:	Tap water, *ad libitum*
Housing:	Four per cage per sex in stainless steel cages (26.5 x 50.0 x 20.7cm)
Environmental conditions:	Temperature: 19-23°C Humidity: 40-70 % Air changes: 25-30/hour Photoperiod: 12 hours light/dark cycle

B: STUDY DESIGN AND METHODS

In life dates: 1995-05-09 to August 1995

Animal assignment and treatment

In a subchronic neurotoxicity study, groups of 12 male and 12 female Alpk:APfSD (Wistar-derived) rats were fed diets containing 0, 2000, 8000 or 20000 ppm glyphosate acid for 13 weeks (equivalent to mean achieved dose levels of 0, 155.5, 617.1 and 1546.5 mg/kg bw/day for males, and 0, 166.3, 672.1 and 1630.6 mg/kg bw/day for females) glyphosate technical.

All diets were based on CT1 diet supplied by Special Diets Services Limited, Stepfield, Witham, Essex, UK. The experimental diets were prepared in 30 kg batches by direct addition of the test substance to 30 kg of CT1 diet and mixing thoroughly. The diets were stored at room temperature until required for use.

Samples from all dietary levels (including controls) were taken at intervals throughout the study and analysed quantitatively for glyphosate acid. The homogeneity of glyphosate acid in CT1 diet was determined by analysing samples from the low and high dose levels. The chemical stability of glyphosate acid in diet, under the conditions of storage used on this study, was determined for 2000 ppm and 20000 ppm diets prepared for use on a concurrent 1 year feeding study in the rat in the same laboratory.

Clinical observations

A check for clinical signs of toxicity, ill health and behavioural changes was made once daily on all animals. All observations were recorded. A detailed physical examination was performed on each rat prior to start of treatment, and at weekly intervals thereafter.

Functional observational battery (FOB)

Prior to the start of treatment and during Weeks -1, 5, 9 and 14, all animals were observed for signs of functional/behavioural toxicity. The assessment involved observations in the home cage and/or while the rat was moving freely in a standard arena followed by manipulative/in hand tests Functional performance tests were also performed together with an assessment of sensory reactivity to different stimuli. The examinations included quantitative assessments of landing foot splay, sensory perception (tail-flick test) and muscle weakness (fore- and hind limb grip strength). The clinical observations included, but were not limited to, the following list: assessment of autonomic function (e.g. lachrymation, salivation, piloerection,

exophthalmus, urination, defecation, pupillary function, ptosis); description, incidence and severity of any convulsions, tremors, abnormal motor function, abnormal behaviour; reactivity to stimuli; changes in level of arousal; sensorimotor responses; alterations in respiration.

Locomotor activity

Locomotor activity was monitored by an automated activity recording apparatus. All animals were tested at weeks -1, 5, 9 and 14. Each observation period was divided into ten scans of five minute duration. Treatment groups were counter balanced across test times and across devices and when the trials were repeated each animal was returned to the same activity monitor at approximately the same time of day. Motor activity was assessed in a separate room to minimise disturbances.

Body weight

Individual body weights were recorded in week -1, immediately prior to treatment, at weekly intervals thereafter, and at necropsy.

Food consumption and compound intake

Food consumption was recorded as required for each cage group throughout the study and calculated on a weekly basis. Food utilisation and compound intake were calculated.

Water consumption

Not reported.

Ophthalmoscopic examination

Not performed. However, ophthalmological data are available from other repeated dose studies.

Sacrifice and pathology

At the scheduled termination, all main study animals not required for neuropathology, were killed by overexposure to rising concentrations of carbon dioxide gas and were discarded without examination.

At termination, the six rats/sex/group designated for neuropathology were deeply anaesthetised with intraperitoneal sodium pentobarbitone and killed by whole body perfusion fixation with modified Karnovsky's solution. The following tissues were submitted: brain, spinal cord (cervical and lumbar), Gasserian ganglion, dorsal root ganglia and spinal roots (cervical and lumbar), gastrocnemius muscle, sciatic nerve, sural nerve and tibial nerve.

Brain weight, brain length and brain width were determined.

Submitted tissues were processed as follows: brain (seven levels including the cerebral cortex, the hippocampus, the cerebellum, the pons and medulla), dorsal root ganglia and spinal roots from cervical and lumbar regions of the cord after decalcification, and gastrocnemius muscle from rats receiving either control diet or diet containing 20000 ppm glyphosate acid were routinely processed, paraffin wax embedded and 5µm thick sections were cut and then stained with haematoxylin and eosin. Sections of brain and cord were in the transverse plane.

The Gasserian ganglion, sciatic nerve, spinal cord (cervical and lumbar portions), sural and tibial nerve from control and high dose group rats were processed and then embedded in Araldite. Semi-thin sections were cut and then stained with toluidine blue. For bilateral tissues only the left was processed. All tissues were sectioned in the transverse plane except the sciatic nerve which was sectioned in both the transverse

and the longitudinal plane.

Neuropathological examination was performed on control and highest dose group animals only. All sections were examined by light microscopy.

Statistics

All data were evaluated using analysis of variance and/or analysis of covariance for each specified parameter using the GLM procedure in SAS (1989)[32]. Least-squares means for each group were calculated using LSMEAN option in SAS PROC GLM. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squared mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a two-sided Student's t-test, based on the error mean square in the analysis.

The levels of probability chosen as significant different from control were $p < 0.01$** and $p < 0.05$* (Student's t-test, two-sided).

II. RESULTS

A. DOSING FORMULATION ANALYSIS

The achieved mean concentrations of glyphosate acid in diet were within 4 % of the nominal levels, with individual values being within 15 % of nominal. There were considered acceptable. The homogeneity of the low- and high-dose diets was considered acceptable, with a deviation from the overall mean values of ± 4 %. The chemical stability was considered satisfactory.

B. MORTALITY

No deaths occurred during the study.

C. CLINICAL OBSERVATIONS

There were no treatment-related clinical signs of toxicity.

D. FUNCTIONAL OBSERVATIONS

Functional observational battery (FOB)

There were no clinical signs that could be attributed to administration of glyphosate acid.

There was an apparent increase in the incidence of miosis and decreased pupil response to light in males receiving 20000 ppm. However, as these signs were seen for several of these males pre-experimentally and were also present at a similar incidence in females with no obvious relationship to treatment, this was considered to be incidental and unrelated to administration of glyphosate acid.

Landing Foot Splay Measurements

There was no evidence of any treatment-related effect on landing foot splay.

Time to Tail-Flick

[32] SAS Institute Inc. SAS/STAT User's Guide, Version 6, Fourth Edition, Volume 2. Cary, NC: SAS Institute Inc., 1989

There was no evidence of any treatment-related effect on time to tail-flick.

Grip Strength Measurements

There was no evidence of any treatment-related effect on forelimb or hind limb grip strength.

Motor activity

There was no evidence of any treatment-related effect on locomotor activity.

During week 5, slightly reduced locomotor activity was recorded on occasions for females receiving 20000 ppm. However, in the absence of any treatment-related effects on motor activity for these animals at other time points during the study, this is considered to be incidental and unrelated to administration of glyphosate acid.

Table 5.7.1-10: Glyphosate Acid: Subchronic Neurotoxicity Study In Rats ([redacted], 1996): Selected motor activity findings

		Dietary concentration (ppm)							
		Males				Females			
Week	Assessment period (min)	0	2000	8000	20000	0	2000	8000	20000
5	1-50	388.7	472.1	335.6	384.4	441.2	379.3	457.8	359.3
9	1-50	304.7	413.4*	298.4	327.3	512.3	488.9	555.1	557.0
14	1-50	299.4	395.1	292.2	372.8	553.0	512.7	569.3	514.7

* Statistically significant difference from control group mean at the 5 % level (Student's t-test, 2-sided)
** Statistically significant difference from control group mean at the 1 % level (Student's t-test, 2-sided)

E. BODY WEIGHT

Group mean bodyweight for males receiving 20000 ppm was statistically significantly lower than that of controls throughout the study. At week 14, group mean bodyweight for these animals was 92.8 % that of controls, equating to a reduction in bodyweight gain of approximately 12 %.

Group mean bodyweight for males receiving 8000 ppm was also marginally lower than that of controls from weeks 6 to 14. However, these differences did not attain statistical significance and were considered too small to be of biological importance.

For males receiving 2000 ppm, and for females at all dose levels, mean bodyweight was essentially similar to that of concurrent controls throughout the study.

Table 5.7.1-11: Glyphosate Acid: Subchronic Neurotoxicity Study In Rats ([redacted], 1996): Intergroup comparison of bodyweights (g)

	Dietary concentration (ppm)							
	Males				Females			
Week	0	2000	8000	20000	0	2000	8000	20000
1	216.0	217.0	218.6	215.0	173.5	178.8	175.6	175.3
2	263.5	264.7	264.9	254.6**	192.7	200.6	196.1	194.3
4	338.2	340.7	339.6	323.7*	214.3	228.3**	224.9**	219.2
8	440.7	440.1	429.1	405.8**	253.6	262.1	260.4	255.4
14	534.7	532.8	526.5	496.1**	285.1	291.5	287.9	281.0

* Statistically significant difference from control group mean at the 5 % level (Student's t-test, 2-sided)
** Statistically significant difference from control group mean at the 1 % level (Student's t-test, 2-sided)

F. FOOD CONSUMPTION AND COMPOUND INTAKE

There were no effects on food consumption. The efficiency of food utilisation for males receiving 20000 ppm was statistically significantly lower than that of concurrent controls during weeks 1 to 8. There were no changes in the efficiency of food utilisation for males receiving 2000 or 8000 ppm or for females from all treated groups.

Table 5.7.1-12: Glyphosate Acid: Subchronic Neurotoxicity Study In Rats ([redacted], 1996): Intergroup comparison of food utilisation (g growth/100 g food)

	Dietary concentration (ppm)							
	Males				Females			
Week	0	2000	8000	20000	0	2000	8000	20000
1-4	18.13	17.16	16.94	16.28*	9.42	9.73	9.36	9.61
5-8	11.52	10.69	10.35	9.93*	5.99	5.55	5.39	5.70
1-13	12.00	11.45	11.38	10.87**	6.08	6.03	6.06	5.96

* Statistically significant difference from control group mean at the 5 % level (Student's t-test, 2-sided)
** Statistically significant difference from control group mean at the 1 % level (Student's t-test, 2-sided)

The mean doses received for males and females respectively were 155.5, 617.1, 1546.5 and 166.3, 672.1, 1630.6 mg glyphosate acid/kg/day at dose levels of 2000, 8000 and 20000 ppm, respectively

G. PATHOLOGY

Brain measurements

There was no evidence of any effects on brain weight, length or width.

Necropsy

There were no macroscopic findings that were considered to be attributable to treatment.

Histopathology

There were no microscopic findings in the peripheral or central nervous system that were considered to be attributable to treatment.

Study conclusion

Dietary administration of glyphosate acid to rats for a period of ninety consecutive days at dietary concentrations of up to 20000 ppm produced evidence of toxicity in the form of reduced growth and reductions in food utilisation for males. Comprehensive histopathological evaluation of the nervous system showed no evidence of any changes in the peripheral or central nervous system which could be attributed to administration of glyphosate acid.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable. No evidence of a neurotoxic potential was obtained up to the highest

dose of 20000 ppm. The no observed effect level (NOEL) for neurotoxic potential, following dietary administration of glyphosate acid for at least 90 days, was 20000 ppm, corresponding to 1546.5 / 1630.6 mg/kg bw/day for males and females, respectively.

Assessment and conclusion by RMS:

CA 5.7.2 Delayed polyneuropathy studies

1. Information on the study

Data point:	CA 5.7.2/001
Report author	[redacted]
Report year	1996
Report title	Glyphosate acid: Acute delayed neurotoxicity study in domestic hen
Report No	[redacted]/C/3122
Document No	NA
Guidelines followed in study	No guideline stated in the report but in general compliance with OECD 418 (1995)
Deviations from current test guideline	None
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Twenty birds were given a single dose of glyphosate acid at a level of 2000 mg/kg bw and observed for the following 21/22 days. Twelve negative control (vehicle, distilled water) and twelve positive control (tri-ortho-cresyl phosphate, TOCP, 1000 mg/kg bw) were also dosed. All birds were observed at least twice daily for any changes in clinical condition. Mortality, bird health and clinical signs were recorded at each observation. Following treatment, the birds were examined daily for signs of delayed ataxia. Bodyweight was measured at weekly intervals. Forty eight hours after dosing, pre-determined birds (three from each group) were examined for brain acetylcholinesterase and brain and spinal cord neuropathy target esterase (NTE) activities. At the end of the 21-day post-treatment observation period six birds from each group were examined histopathologically.

No clinical signs of delayed locomotor ataxia were observed in any birds treated with glyphosate acid. Five birds in the positive control group developed clinical ataxia. Brain acetylcholinesterase activity was slightly depressed in birds treated with glyphosate acid and TOCP. This was considered to be of no toxicological significance. Brain and spinal cord neuropathy target esterase (NTE) activities in birds treated with glyphosate acid were similar to negative controls. In the positive control group NTE activity was significantly reduced. Over the 21-day post-treatment period body weight gains were observed in the negative control and in the birds dosed with glyphosate acid. Most birds dosed with TOCP lost weight over

the same period. At necropsy, no changes attributable to treatment with glyphosate acid were detected. Histopathological examination revealed no evidence of acute delayed neurotoxicity or any other treatment-related changes in glyphosate acid-treated hens.

In conclusion, oral administration of a single dose of glyphosate acid at dose level of 2000 mg/kg bw did not produce any clinical signs of delayed neurotoxicity when assessed in terms of clinical ataxia. There was no histological evidence of acute delayed neurotoxicity, and there were no significant reductions in neuropathy target esterase levels in the brain and spinal cord. Therefore, the NOAEL for acute delayed neurotoxicity, following single oral administration of glyphosate acid was 2000 mg/kg bw.

I. MATERIALS AND METHODS

A: MATERIALS

1. Test material:

Identification:	Glyphosate acid
Description:	White powder
Lot/Batch #:	P24 (Y04707/034/023)

B: STUDY DESIGN AND METHODS

In life dates: 1996-01-09 to 1996-02-14.

Animal assignment and treatment

Twenty hens were administered glyphosate acid as a single dose of 2000 mg/kg bw by oral gavage. Twelve birds were employed as positive controls and received a single dose of 1000 mg TOCP/kg bw. The negative control group consisted also of 12 hens and received once distilled water also by gavage. The same volume of 10 mL/kg bw was applied to all hens. Treatment was followed by an observation period of 21 or 22 days.

Dosing Formulation Analysis

Verification of the achieved concentrations was done with samples of each preparation. Homogeneity and the chemical stability of glyphosate acid in water was also determined over a period of 2 hours.

Clinical observations

A check for mortality, clinical signs of toxicity, ill health and behavioural changes was made twice daily on all birds.

Body weight

Individual body weights were recorded weekly.

Food consumption

Food consumption was not recorded

Ataxia assessment

Following treatment, hens were examined daily for signs of (delayed) ataxia.

Sacrifice and pathology

Three pre-determined chicken from each group were sacrificed 48 hours after dosing to determine brain cholinesterase, brain neuropathy target esterase and lumbar spinal cord neuropathy target esterase (NTE) activities.

At the scheduled termination, 6 hens from each group were selected for necropsy and histopathological examinations. Whereas in the negative control and glyphosate-treated groups the first six birds in numerical order (because of the absence of clinical signs) were employed, care was taken in the TOCP-treated group to include all animals that had shown clinical ataxia. The remaining hens from all three groups were killed and discarded.

At termination, after perfusion through the heart with fixative, head and spinal column (with brain and spinal cord exposed but left in place) and dissected sciatic nerves (including tibial branches) from the six hens/group designated for neuropathology were taken and stored. The following tissues were used to take samples for histological examination: brain (forebrain, mid and hindbrain), spinal cord (upper and lower cervical, mid-thoracic and lumbo-sacral parts), sciatic nerve (proximal and distal, above knee), tibial nerve. One transverse and two longitudinal sections were performed at each level.

Statistics

No statistical analysis was necessary since the results were quite clear and number of animals limited.

II. RESULTS

A. DOSING FORMULATION ANALYSIS

The achieved concentrations of glyphosate acid in water were within 4 % of the nominal levels. The results confirm that the formulations were homogenous and stable during ambient temperature storage for 2 hours, a period representing the maximum time from preparation to completion of dosing.

B. MORTALITY AND CLINICAL OBSERVATIONS

There were two unscheduled deaths during the study. In the test group receiving glyphosate acid, one bird was found dead on day 10 after dosing. This hen had not exhibited any signs of toxicity prior to death. The cause of death was apparently not elucidated but in the absence of clinical signs and isolated occurrence it was concluded that this mortality was unrelated to treatment. In the positive (TOCP) control group, one bird had been severely pecked by other hens and was sacrificed on humane grounds, during the acclimation period.

In the glyphosate-treated and negative control groups, there were no uncommon clinical signs observed. In the positive control group one more hen was pecked and had to be treated by applying Stockholm tar to the wounds.

C. BODY WEIGHT

Group mean body weight increased in the glyphosate-treated and negative control groups but weight loss was observed in the positive controls receiving TOCP.

D. FOOD CONSUMPTION

food consumption was not recorded.

E. ATAXIA ASSESSMENT

Ataxia was confined to the positive control group receiving 1000 mg TOCP/kg bw. Five of 11 hens were affected. Signs occurred for the first time between post-observation days 11 and 21. The severity of ataxia ranged from 1 – 5 (No ataxia to continuous staggering gait) in a scale of 0-8.

F. PATHOLOGY

Clinical chemistry

In line with ataxia observations, NTE levels in brain and spinal cord were clearly reduced in the positive control group (by 84 % for brain and by 78 % for spinal cord as compared to negative control group) but no effect was seen in the group receiving glyphosate. A very low reduction of brain cholinesterase (mean 6 % less than in negative control) was seen in the hens that had that received glyphosate. In the positive control group, the mean decrease in brain cholinesterase activity was 19 %. No statistical analysis was possible in the study due to the low number (3) of birds investigated. Taking into account the very low difference to negative control birds and the fact that glyphosate is known not to inhibit cholinesterases, a treatment-related effect is unlikely.

Table 5.7.2-1: Glyphosate acid: Acute delayed neurotoxicity study in domestic hen ([redacted], 1996): Clinical chemistry – group mean values

		Group/treatment		
		Negative control **Mean ± SD**	**Glyphosate acid 2000 mg/kg bw** **Mean ± SD**	**Positive control 1000 mg/kg bw TOCP** **Mean ± SD**
Brain	AChE	12.75	11.95 (-6 %)	10.37 (-19 %)

[µmol/g/min]			
Brain NTE [nmol/g/min]	2232	2436 (+9 %)	360** (-84 %)
Spinal cord NTE [nmol/g/min]	544	547 (+1 %)	118** (-78 %)

Number in parentheses refer to percentage reduction in relation to negative control
** $p<0.01$

Necropsy

There were no macroscopic findings that were attributable to treatment.

Histopathology

The evaluation of histological findings is complicated by the fact that axonal degeneration in the spinal cord and peripheral nerves were observed in all three groups in nearly all birds suggesting high background incidence. In the TOCP-treated group, the cerebellum was also affected in five out of six animals (as compared to only one bird in the glyphosate group). Furthermore, axonal degeneration in general was more severe in the positive control group.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered acceptable. Hens receiving glyphosate showed no occurrence of ataxia nor changes in NTE activity. Thus, no delayed neuropathy was observed for glyphosate. Observations of a positive control group receiving TOCP (1000 mg/kg) confirmed the sensitivity of the test. In conclusion, the NOAEL for acute delayed neurotoxicity, following single oral administration of glyphosate acid was 2000 mg/kg bw.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.7.2/002
Report author	[redacted]
Report year	1987
Report title	A 21 Day Oral Neurotoxicity in Domestic Hen of Glyphosate (technical) of Excel Industry Limited
Report No	NA
Document No	NA
Guidelines followed in study	No guideline followed
Deviations from current test guideline	Major deviations from currently adopted OECD 419 (only 21 days treated and no post treatment observation performed). It should be noted that at the time this study was run OECD 419 recommended 90 days exposure but no post exposure observation period.
Previous evaluation	Not accepted in RAR (2015)

Category study in AIR 5 dossier (L docs)	Category 3b

2. Full summary

Groups of three birds per dose were orally administered daily doses of 0, 250, 500, or 1000 mg/kg bw/day glyphosate in corn oil for 21 consecutive days. The hens were examined at least once daily for signs of overt toxicity. Body weights and egg weights were recorded daily. Food consumption was recorded on days -7 and -3 before the study and on days 1, 4, 8, 11, 15, 18 and 21 during the treatment period. Blood samples were collected from alar vein and haematological and biochemical parameters were monitored prior to treatment, on the 11th day of the study and at termination. Spinal cord and sciatic nerve were histologically analysed using Holmes silver stain.

All hens survived the treatment period and did not exhibit any signs of neurotoxicity except one high dose hen showing slight ataxia on day 18. All hens of the highest dose group appeared hunched and lethargic from day 5 to 11. Red liquid and matting of feathers in anogenital region were noticed from day 16 to the end of the study. In the other groups, hens did not exhibit any clinical symptoms. An overall reduction in body weight of about 20 % as well as a decrease in food consumption occurred in the highest dose group. A slight reduction in haematological parameters (haemoglobin, packed cell volume and red blood cell count) was also found in this group. Blood chemistry, gross pathology and histology did not provide indications of adverse effects. Egg weight were unaffected in all hens.

In conclusion, oral administration of glyphosate for 21 consecutive days up to 1000 mg/kg bw/day did not produce neurotoxicity. Systemic toxicity was observed in the 1000 mg/kg bw/day group.

In life dates: Not provided in the study report.

Animal assignment and treatment

Twelve hens were allocated to four dose groups: control (0 mg/kg bw/day), low (250 mg/kg bw/day), mid (500 mg/kg bw/day, and high (1000 mg/kg bw/day). Glyphosate in corn oil was administered by oral intubation into the crop once daily for 21 days.

Dosing Formulation Analysis

No information provided.

Clinical observations

The hens were examined at least once daily for signs of ill health or overt toxicity.

Body weight

Individual body weights were recorded daily from day -7 of the pre-dose period and throughout the treatment period.

Egg weight

The eggs were collected daily and their weights were recorded.

Food consumption

Group food consumption was recorded on days -7 and -3 before the start of the treatment and on days 1, 4, 8, 11, 15, 18, and 21 during the treatment period.

Ataxia assessment

The hens were examined daily and the findings were recorded for each hen. The following score system was used:

No ataxia	0
Doubtful or minor signs	1 (leg weakness)
Positive paralytic signs	2 (lack of leg coordination, loss of balance, tendency to fall back)
Advanced paralytic signs	3 (inability to walk, ataxia, hyperextension, complete prostration and morbidity)
Death	4

Haematology

Blood samples were collected from alar vein and the haematological parameters were examined prior to treatment, on the 11th day of treatment and at termination of the study. The following parameters were examined: haemoglobin (Hb), packed cell volume (PCV), red blood cell count (RBC), white blood cell count (WBC), neutrophils (N), lymphocytes (L), eosinophils (E), basophils (B).

Clinical chemistry

Blood samples were collected from alar vein and the biochemical parameters were examined prior to treatment, on the 11th day of treatment and at termination of the study. The following parameters were examined: serum glutamic pyruvate transaminase (SGPT), serum alkaline phosphatase (SAP), total serum protein, blood urea nitrogen (BUN), cholinesterase (in plasma) (ChE).

Sacrifice and pathology

The hens were killed intravenous injection of pentobarbitone sodium and exsanguinated by cutting cervical blood vessels.
The brain was removed intact and was fixed in 10 % formalin. The entire spinal cord along with the vertebral column was excised and fixed in 10 % formalin containing formic acid. Both sciatic nerves, together with the proximal part of the pereneal and tibial nerves of each leg were removed along with some muscle and fixed in 10 % formalin.
The following tissue from all hens were preserved: brain (intact), spinal cord (entire cord in the vertebral column), sciatic nerves (disted endes, together with the proximal part of the pereneal and tibial nerves with some muscle attached from leg). Transverse and longitudinal sections were made both sciatic nerves and proximal ends of the pereneal and tibial nerves. The spinal cord and sciatic nerve from all the hens were processed to paraffin wax blocks, sections cut at nominal thickness of 10 µm and stained with Holmes silver stain.

Statistics

No information provided.

II. RESULTS

A. DOSING FORMULATION ANALYSIS

Not applicable.

B. MORTALITY AND CLINICAL OBSERVATIONS

All hens survived the treatment period. Hens of the control, low and mid dose groups did not exhibit any clinical symptoms. All hens of the high dose group appeared hunched and lethargic from day 5 to day 11. Red liquid and matting of feathers in anogenital region was seen in all the hens of the high dose group on day 16 onwards.

C. BODY WEIGHT

Overall reduction in body weight of about 20 % occurred in the hens of the high dose group only. The body weights of the low and mid dose groups were found to be comparable with those of hens of the control group.

Table 5.7.2-2: A 21 Day Oral Neurotoxicity in Domestic Hen of Glyphosate (technical) of Excel Industry Limited ([redacted], 1987): Intergroup comparison of body weight (kg)

Dose level of glyphosate (mg/kg bw/day)				
	0 (control) Mean ± SD	250 Mean ± SD	500 Mean ± SD	1000 Mean ± SD
Day 1	2.31 ± 0.14	2.42 ± 0.22	2.47 ± 0.12	2.37 ± 0.09
Day 5	2.34 ± 0.13	2.40 ± 0.25	2.42 ± 0.08	2.36 ± 0.10
Day 10	2.29 ± 0.14	2.43 ± 0.23	2.41 ± 0.10	2.36 ± 0.13
Day 15	2.31 ± 0.13	2.42 ± 0.24	2.38 ± 0.10	2.27 ± 0.11
Day 20	2.29 ± 0.16	2.38 ± 0.22	2.35 ± 0.12	2.02 ± 0.13
Day 22	2.32 ± 0.12	2.41 ± 0.22	2.38 ± 0.14	1.91 ± 0.11

Egg weights: There was no significant difference in the number of egg laid in control, low and mid dose groups. Slight reduction in the number of eggs laid in the high dose group was observed.

D. FOOD CONSUMPTION

The food consumption was unaffected in control hens and hens of low and mid dose group. Food consumption was progressively reduced in the high dose group from day 8 compared to the control group.

Table 5.7.2-3: A 21 Day Oral Neurotoxicity in Domestic Hen of Glyphosate (technical) of Excel Industry Limited ([redacted], 1987):Intergroup comparison of food consumption (g)

Dose level of glyphosate (mg/kg bw/day)				
	0 (control)	250	500	1000
Day -7 to -1	1880	1740	1590	1830
Day 1 to 7	1760	1680	1810	1770
Day 8 to 14	1690	1870	1750	1310
Day 14 to 21	1830	1940	1710	830

E. ATAXIA ASSESSMENT

No hens exhibited any signs of neurotoxicity during the study except one hen of the high dose group which showed slight ataxia on day 18.

F. HAEMATOLOGY AND CLINICAL CHEMISTRY

Slight reduction in Hb, PCV and RBC was noted in hens of the high dose group at the end of treatment as compared to those in control hens. No changes in haematological parameters were found in the low and mid dose group.

The levels of SGPT, SAP, BUN, total serum protein and blood sugar were comparable in treated hens compared to the control hens.

H. PATHOLOGY

Necropsy

There were no macroscopic findings that were attributable to treatment.

Histopathology

There were no evidence of neurological changes in the spinal cord and peripheral nerves of treated hens and control hens.

3. Assessment and conclusion

Assessment and conclusion by applicant:

To evaluate delayed neurotoxicity this study is considered to be not valid due to major deviations from the current guideline protocol. However, it can be regarded as supportive, that glyphosate does not elicit delayed neurotoxicity in hens up to a dose of 1000 mg/kg bw/day orally for 21 days.

Assessment and conclusion by RMS:

Publications on neurotoxicity

A literature search for the active substance glyphosate was performed in accordance to the provisions of the EFSA Guidance "Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) 1107/2009" and updated Appendix to this Guidance document. The following publications were found relevant and reliable for this section and the summaries are thus presented below and are part of the general discussion at the beginning of the section.

Table 5.7- 1: Overview on literature found relevant for evaluation of glyphosate in section 5.7

Annex Point	Study	Study type	Substance(s)	Reliability & restriction comments	Result
CA 5.7/001	Martinez *et al*., 2019	Acute neurotoxicity, *in vitro* Induced pluripotent stem cells	Glyphosate (Sigma Aldrich, Purity: analytical grade)	Valid, Category 2a Glyphosate and AMPA not adequately characterized No positive controls to verify assays	High levels of glyphosate (100 µM) may result in neurological damage
CA 5.7/002	Martinez *et al*, 2018	Acute neurotoxicity, oral gavage Wistar rats	Glyphosate (Purity: ≥ 98 %)	Valid, Category 2a No positive or negative historical controls No concurrent positive historical control No dose verificaiton	loss of 5-HT, DA and NE levels in CNS
CA 5.7/003	Chorfa *et al*, 2013	Acute neurotoxicity, *in vitro* human neuroblastoma (SH-SY5Y) and melanoma (SK-MEL-2) cell lines	Glyphosate (Sigma Aldrich, Purity: 99.5 %)	Valid, Category 2a No positive control Only two dose groups	No effects observed

2. Full summary of the study according to OECD format

In this study, the effect of acute exposure to glyphosate (GPH) on the blood-brain barrier in vitro was investigated based on induced pluripotent stem cells (iPSCs). Two chemical analogues: aminomethylphosphonic acid (AMPA) and glycie (GLY) were used as comparators, Concentrations tested ranged from 0.1 µM to 1000 µM..

I. MATERIALS AND METHODS

Chemicals - Glyphosate (EPA 547 1,000 µg/mL solution), aminomethylphosphonic acid (AMPA) and glycine (GLY) were purchased as analytical grade reagents from Sigma-Aldrich, St. Louis, USA. The purity of the test chemicals was not reported.

Cell culture - Induced pluripotent stem cell line IMR90-c4 iPSC (RRID: CVCL_C437) was purchased from WiCell cell repository (WiCell, Madison, WI). iPSC colonies were maintained on hPSC-grade growth factor reduced Matrigel (C-Matrigel, Corning, Corning, MA) in the presence of Essential 8 medium (E8, ThermoFisher, Waltham, MA).

iPSC differentiation - iPSCs were differentiated into brain microvascular endothelial cells (BMEC). iPSCs were seeded as single cells on T-Matrigel at a cell density of 20,000 cells/cm^2 in E8 supplemented with 10 µM Y-27632. 24 hours after seeding, cells were maintained in E8 for 5 days prior to differentiation. Cells were maintained for 6 days in unconditioned medium (UM: DMEM/F12 with 15 mM HEPES, 20 % knockout serum replacement, 1 % non-essential amino acids, 0.5 % Glutamax and 0.1 mM β-mercaptoethanol). After 6 days, cells were incubated for 2 days in the presence of EC+/+ (EC medium supplemented with 1 % platelet-poor derived serum, 20 ng/mL human recombinant basic fibroblast growth factor (bFGF) and 10 µM retinoic acid). After such maturation process, cells were dissociated by Accutase® treatment and seeded as single cells on tissue-culture plastic surface (TCPS) coated with a solution of collagen from human placenta and bovine plasma fibronectin at 80 µg/cm^2 and 20 µg/cm^2, respectively. Twenty-four hours after seeding, cells were incubated in presence of EC-/- (EC medium supplemented with 1 % platelet poor derived serum (PDS)). Barrier phenotype experiments were performed 48 hours after seeding. Differentiation of iPSCs into neurons was done using an adherent 3-step differentiation method. Co-culture experiments were performed by seeding iPSC-derived BMECs at day 8 of differentiation on inserts juxtaposed over 16-days iPSC-derived neurons. BMECs were maintained in EC medium, whereas neurons were maintained in neuron maturation medium (NMM).

Glyphosate, AMPA and glycine treatment - Dilutions of glyphosate, AMPA and glycine were made immediately before the experiments and maintained in cell medium for 24 or 48 hours. In co-culture experiments, the test compounds were added in the apical chamber at a concentration of 100 µM and incubated for 6 hours. iPSC-derived neuron monocultures exposed to similar concentrations served as controls.

Cell metabolic activity - Following treatment, CellTiter Aqueous® MTS reagent ([3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium, inner salt) was added to each sample following recommendations by the manufacturer. Cells were maintained for 60 minutes at 37 °C followed by a measurement of absorbance at 490 nm using an ELISA plate reader.
Absorbance obtained from the test samples were subtracted from background absorbance and normalized against controls (untreated cells).

iPSC-derived BMECs barrier function - iPSC-derived BMECs were seeded at a seeding density of 10^6 cells/cm^2 on Transwells (polyester, 0.4 µm pore size, Corning) and coated as previously described. Barrier function was assessed 48 hours after seeding of iPSC-derived BMECs monolayers. Barrier tightness was measured by assessing both the transendothelial electrical resistance (TEER) and paracellular diffusion. TEER was measured using an EVOHM STX2 chopstick electrode. For each experiment, three measurements were performed for each insert and the average resistance obtained was used for the determination of the barrier function.

Fluorescein, glyphosate and mannitol permeability assay - To assess changes in paracellular permeability, sodium fluorescein was added in the apical (top) chamber at a final concentration of 10 µM. 100 µL aliquots were sampled from the basolateral (donor) chamber every 15 minutes for up to 60 minutes. Each aliquot sample was replaced with 100 µL of cell medium. Fluorescein content in the samples was assessed using a fluorimeter ELISA plate reader. Glyphosate permeability was assessed by incubating cells in the presence of 100 µM glyphosate dissolved in EC-/- in the apical chamber. Sampling in the basolateral chamber occurred as previously described. For the determination of glyphosate the samples taken were alkalinized with 17 µL of borax solution followed by the addition of 17 µL of 9-fluorenylmethoxycarbonyl chloride (FMOC-Cl) solution for the derivatisation of glyphosate. Samples were allowed to incubate in the dark under gentle shaking for 2 hours. The derivatisation process was terminated by adding 137 µL dichloromethane. The sample was homogenized and centrifuged at 2000 rpms for 5 minutes to separate the organic phase and analysis by spectrophotometry at 265 nm. Blank EC-/- medium was used as the blank, whereas glyphosate dissolved in EC-/- at concentrations ranging from 10 nM to 10 µM was used to establish a standard curve. For the measurement of mannitol permeability, [^{14}C] D-mannitol was added in the apical chamber with sampling in the basolateral chamber as described previously. Radioactivity was assessed by adding 100 µL sample to 5 mL liquid scintillation cocktail and counted using a Beckman-Coulter LS6500 liquid scintillation counter. The permeability across BMECs monolayers was obtained by calculating the clearance slope from both samples and blank inserts and by the calculation of the Pe value.

Immunocytochemistry - Cells were stained on tissue culture polystyrene (TCPS) plates and fixed with 4 % paraformaldehyde. Cells were blocked for 1 hour at room temperature in PBS supplemented with 10 % normal goat serum (PBS-G) with 0.2 % Triton-X100 and were then incubated overnight in the presence of claudin-5, occludin, GLUT1 or βIII tubulin. Cells were washed with PBS containing 1 % bovine serum album, and incubated in the presence of Alexa Fluor®-488 conjugated secondary antibodies for 1 hour at room temperature. Thereafter the cells were counterstained with DAPI and observed on a Leica inverted epifluorescence microscope. Micrograph pictures were acquired using Leica Acquisition Suite X and processed using ImageJ. Semi-quantitative analysis was done by measuring the average fluorescence intensity of each micrograph picture using the built-in measure tool in ImageJ. Average fluorescence values from negative controls were subtracted from the fluorescence values obtained in the test samples.

Flow cytometry - iPSC-derived BMECs at Day 10 of differentiation were treated with 100 µM glyphosate, AMPA or glycine for 24 hours. Cells were harvested by enzymatic dissociation using Accutase® and fixed with 4 % paraformaldehyde. Cells were blocked in PBS-G supplemented with 0.2 % Triton-X100 dissolved in PBS for 30 minutes, following by an overnight incubation at 4 °C in primary antibody solution (GLUT-1, SPM498 dissolved in PBS-G). Cells were then washed with PBS containing 1 % BSA and incubated in the presence of Alexa Fluor® 555-conjugated antibody. As isotype control, cells were exposed to mouse IgG as primary antibody and analysed using a BD FACSVerse®, with a fluorescence photomultiplier tube (PMT) adjusted to IgG isotype control. Fluorescence intensity for each sample was obtained from a count of 10,000 cellular events. Median fluorescence intensity (MFI, geometric mean) was

determined for each sample and corrected against IgG isotype.

Glucose and doxorubicin uptake assay - Glucose uptake assays were performed by incubating cells grown on TCPS in presence of cell medium supplemented with [^{14}C] D-glucose. Cells were incubated for 60 minutes at 37 °C. Afterwards the cells were washed with ice-cold PBS and homogenized with PBS + 0.2 % Triton-X100 for 10 minutes. Radioactivity was assessed by adding 100 µL sample to 5 mL liquid scintillation cocktail and counted using a Beckman-Coulter LS6500 liquid scintillation counter. The doxorubicin uptake assay was performed by pre-incubating iPSC-derived BMECs in the presence of glyphosate, AMPA or glycine at 100 µM for 2 hours. Doxorubicin was added to obtain 5 µM as a final concentration and allowed to incubate for 1 hour. Cells were homogenized as previously described and total fluorescence assessed by fluorimetry. Total protein content obtained from cell homogenates was determined using a BCA protein assay.

Statistical analysis - Cells were randomly assigned treatment conditions prior each experiment. Data are represented as mean ± S.D. from three or more independent experiments. One-way analysis of the variance (ANOVA) coupled with Dunnett (or Kruskal-Wallis) tests analysis were performed using Prism 7.0 built-in package (GraphPad Software). A p-value < 0.05 was considered as statistically significant.

II. RESULTS

BMEC cell viability – For the assessment of the effect of glyphosate on the viability of BMECs cell monolayers a range of concentrations was used partially overlapping the levels found in patients reported as asymptomatic, minor and moderate (17, 241, and 428 µM, respectively). Treatment with glyphosate, AMPA or glycine for 24 hours at concentrations ranging from 10 to 1000 µM resulted in no changes in cell metabolic activity. This indicates that glyphosate and AMPA unlikely have toxicity towards the blood-brain barrier.

Fluorescein permeability in BMECs monolayers - Changes in the barrier function in BMECs monolayers were measured using TEER and fluorescein permeability. In addition to the previous concentrations used, 2 concentrations (0.1 and 1 µM) were included to reflect average plasma concentrations reported in occupational exposure. No changes in TEER were noted for any of the concentrations tested of glyphosate, AMPA or glycine. However, a biphasic response was noticed in fluorescein permeability. At 0.1 µM, a slight but not statistically significant decrease in fluorescein permeability was found for glyphosate, AMPA and glycine followed by a statistically significant increase for both glyphosate and AMPA at 1 and 10 µM but not at 100 and 1,000 µM. To confirm the increase in the paracellular profile of glyphosate, changes in paracellular permeability were investigated using [^{14}C]-mannitol, an alternative paracellular flux marker at 1 and 10 µM. A modest but statistically significant increase in mannitol permeability was observed at 10 µM glyphosate. No significant increase was noted following AMPA or glycine treatment.

Tight junction complexes integrity - To better understand the effect of glyphosate and AMPA on the barrier function, changes in tight junction complexes were investigated, in particular changes in claudin-5 and occludin, by immunocytochemistry. No changes in claudin-5 immunolocalisation were observed. However, a dose-dependent decrease in claudin-5 relative expression was noted in all groups as quantified by fluorescence intensity. Glyphosate decreased claudin-5 fluorescence intensity at 100 and 1000 µM, but treatment with AMPA already decreased significantly claudin-5 fluorescence intensity at 10 µM. No changes in occludin localization occurred following treatment although a significant decrease in occludin protein levels was noted in all treatment groups with the exception of 10 µM glyphosate. Unlike claudin-5, this effect appeared to be dose-independent.

Diffusion across the BBB - The ability of glyphosate to cross the blood brain barrier (BBB) was investigated following a single exposure at 100 µM in the apical chamber for 2 hours and measurement of the amount of glyphosate present in the basolateral chamber. After 2 hours of diffusion, the amount of glyphosate capable of crossing BMEC monolayers was about 1.67 ± 0.31 % of the applied dose. It was found that the permeability of glyphosate was significantly greater than fluorescein (18.67 ± 3.55 × 10^{-6} cm/min versus

10.59 × 10^{-6} cm/min) or mannitol (13.10 ± 2.03 × 10^{-6} cm/min). Also the effect of glyphosate and AMPA on drug efflux transporters was investigated using doxorubicin as a drug efflux substrate. With the exception of AMPA that showed a 2-fold increase over control, exposure to 100 µM glyphosate or glycine for 24 hours showed no differences compared to controls.

Modulation of glucose uptake in BMECs - As previous studies reported changes in glucose levels in certain vertebrates following exposure to glyphosate and AMPA changes in GLUT1 (the main glucose transporter at the BBB) localization and expression in BMECs following treatment by immunocytochemistry were studied. Following exposure at 100 µM glyphosate, but not at 1,000 µM, an apparent increase in GLUT1 immunoreactivity was noted. Similar results were obtained with AMPA although less pronounced. A flow cytometry analysis was performed where changes in mean fluorescence indexes were compared following exposure at 100 µM for 24 hours. Exposure to glyphosate yielded an increase in GLUT1 expression levels compared to control. Although AMPA showed no differences in GLUT1 expression, glycine exposure resulted in a significant decrease compared to control.

Barrier function of neurons co-cultured with BMECs - As glyphosate showed the ability to cross the BBB and produced changes in GLUT1 expression and glucose uptake in BMECs monolayers, the effects of glyphosate on neurovascular coupling using a BMEC/neurons co-culture model was investigated. First, the ability of such co-cultures to yield barrier function was assessed by measuring differences in TEER between BMECs monocultures and BMECs co-cultured with iPSC-derived neurons. A 3-fold increase in TEER in BMECs co-cultured with neurons compared to BMECs maintained in monocultures was observed. These co-cultures were then exposed to 100 µM glyphosate, AMPA or glycine for 24 hours. TEER measurements indicated that there was no statistically significant difference in barrier tightness when compared to controls. A mild increase in fluorescein permeability was noted with glyphosate when compared to control, but not with AMPA or glycine.

Neurovascular coupling - The effect of glyphosate on neurovascular coupling was investigated by measuring changes in neural cell metabolic activity using MTS following exposure to 100 µM for 6 hours. A significant decrease in cell metabolic activity was observed in co-cultured neurons when compared to monocultures. When co-cultured neurons were exposed to glyphosate and AMPA the metabolic activity was statistically significantly increased when compared to controls. Glyphosate and AMPA produced no statistically significant changes in metabolic activity of mono-cultured neurons. When the effect of glyphosate, AMPA and glycine was investigated in iPSC-derived neuron colonies by immunocytochemistry against βIII-tubulin, no changes were observed both in monocultures and co-cultures, suggesting that changes in cell metabolic activity is unlikely due to cell death.

Neuron progenitor cells (NPC) - The effect of glyphosate on differentiating and differentiated neurons was investigated by exposing cells to a concentration considered representative of the amount crossing the BBB i.e. 0.1–1 µM. First, the effect of an exposure of 24 hours on the cellular metabolic activity of undifferentiated NPCs was investigated using the MTS assay. A significant decrease in cell metabolic activity was seen at concentrations of glyphosate and glycine of 1 µM although immunofluorescence analysis of these NPCs showed no major alterations in the relative cell density and nestin (a cellular marker of neural stem cells/progenitor cells) immunoreactivity. Then, differentiating NPCs were treated continuously for 16 days (by replacing cell medium every 48 hours) in the presence of 0.1 µM glyphosate, AMPA or glycine. The concentration tested is representative of plasma concentrations reported in occupational workers and is 20 times higher than values reported in non-occupational population. No significant changes in cell metabolic activity were observed between the different groups compared to controls. After 16 days of exposure to glyphosate or AMPA no changes in gross morphology of iPSC-derived neuron colonies were evident.

Neurites density - The exposure of iPSC-derived neurons seeded at low density (50,000 cells/cm^2) to glyphosate or AMPA for 24 hours at concentrations ranging from 1 µM to 1000 µM decreased statistically significantly cell metabolic activity at 10 µM and beyond. AMPA showed similar results, albeit not statistically significant. Treatment with glycine showed only small effects on cell metabolic activity.

Changes in cell density and neurites formation by immunocytochemistry were also investigated and, with the exception of glycine, no depletion in neurites was observed with glyphosate and AMPA. Upon quantification of cell nuclei and neurites per surface area a progressive decrease in neuron density was noted for both glyphosate and AMPA, with a significant decrease at 1000 µM. However, no differences in neurite density were noted with glyphosate and AMPA, with the exception of glycine at 100 and 1000 µM.

Discussion
The toxicity of acute glyphosate poisoning on blood-brain barrier integrity was investigated by assessing its activity on the different cell types of the neurovascular unit. Cells were exposed to glyphosate and AMPA at concentrations ranging from 10 to 1000 µM. This is the concentration range of glyphosate plasma values in patients with self-inflicted poisoning. An increase in fluorescein permeability was noted for glyphosate and AMPA at 1 µM and 10 µM. A similar outcome was noted for mannitol in cells exposed to 1 µM glyphosate. This suggests a possible detrimental effect of glyphosate and AMPA on blood-brain barrier function. Although no major changes in tight junction complexes localization were observed, a decrease was found in both claudin-5 and occludin protein levels after exposure to glyphosate, AMPA and glycine, suggesting that glyphosate and AMPA may interfere with tight junction complexes integrity. Yet, the interference of such compounds on tight junction proteins remains unclear. Although not statistically significant, a 50 % increase in paracellular permeability was noted with glycine at 100 and 1000 µM. The data from this study suggest that high levels of glycine may increase the permeability of the BBB and disrupt tight junction complexes. In addition to changes in barrier function, glyphosate permeability in BMEC monolayers was assessed. It is estimated that about 1 % of the applied dose (100 µM) diffused across BMECs monolayers. However, the permeability for glyphosate was significantly higher than that for fluorescein despite its high hydrophilicity (xLogP = -4.63). This indicates that glyphosate crosses the BBB via carrier-mediated diffusion. Amongst the different cell types, neurons displayed the most important changes in metabolic activity following exposure to glyphosate and AMPA. Significant changes in neuronal cell metabolic activity were observed following exposure to glyphosate, AMPA or glycine whereas such changes we not observed in BMECs. Such decrease in cell metabolic activity was unlikely to be considered as neurotoxicity since these effects didn't translate in changes in neuronal cell density and neurites formation. The change in cell metabolic activity observed may be due to changes in glucose metabolism, as changes in glucose uptake in BMECs, as well as some changes in GLUT1 expression levels were noted.

III. CONCLUSION

The data from this study demonstrate the relative safety of glyphosate and AMPA with regard to the blood-brain barrier after acute exposure with minimal effects observed at concentrations significantly higher than baseline exposure levels, occupational and non-occupational alike. The presence of an active uptake and diffusion of glyphosate across the blood-brain barrier suggests the need of extensive brain-centered studies to evaluate the pharmacokinetics and pharmacodynamics of glyphosate on the central nervous system during acute exposure and in individuals exposed to high amounts of such pesticides.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The effect of glyphosate, AMPA and glycine was investigated on the integrity of the blood-brain barrier *in vitro* using an induced pluripotent stem cell line differentiated into brain microvascular endothelial cells (BMEC) and neurons. The endpoints investigated were BMEC cell viability, fluorescein permeability in BMEC cell monolayers, tight junction complexes integrity, diffusion across the blood-brain barrier, modulation of glucose uptake in BMECs, barrier function of neurons co-cultured with BMECs, neurovascular coupling, differentiation of neuron progenitor cells and neurites density. The results of this study indicate that glyphosate or AMPA are unlikely to present toxicity towards the blood-brain barrier. Minimal effects on single parameters were observed with glyphosate or AMPA, but were comparable with effects of the amino acid glycine.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because the glyphosate used was not sufficiently characterized and no positive controls were used in any of the assays conducted.

Assessment and conclusion by RMS:

Reliability criteria for *in vitro* toxicology studies

Publication: Martinez *et al.,* 2019	Criteria met? Y/N/?	Comments
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines	N	
Study performed according to GLP	N	
Study completely described and conducted following scientifically acceptable standards	Y	
Test substance		
Test material (Glyphosate) is sufficiently documented and reported (i.e. purity, source, content, storage conditions)	Y	Purity of glyphosate and AMPA not reported. Source: Sigma-Aldrich, St. Louis, USA.
Only glyphosate acid or one of its salts is the tested substance	N	Also glycine and AMPA tested.
AMPA is the tested substance	Y

Guidelines followed in study	None
Deviations from current test guideline	Not applicable
Previous evaluation	None
GLP/Officially recognised testing facilities	No, not conducted under GLP/Officially recognised testing facilities
Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

The effects of glyphosate oral exposure on brain region monoamine levels in male Wistar rats were examined. Glyphosate-treated rats (35, 75, 150 and 800 mg/kg bw, 6 days), had no visible injury, i.e., no clinical signs of dysfunction were observed. After the last dose of glyphosate, the levels of serotonin (5-HT), dopamine (DA) and norepinephrine (NE) and its metabolites were determined in the brain regions striatum, hippocampus, prefrontal, cortex, hypothalamus and midbrain, by HPLC. Glyphosate caused statistically significant changes in the 5-HT and its metabolite 5-hydroxy-3-indolacetic acid (5-HIAA), DA and its metabolites 3,4-hydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), and NE and its metabolite 3-metoxy-4-hydroxyphenylethyleneglycol (MHPG) levels in a brain regional- and dose-related manner. Moreover, glyphosate, dose-dependently, evoked a statistically significant increase in 5-HT turnover in striatum and hypothalamus and in DA turnover in prefrontal cortex and hippocampus, and a statistically significant decrease in NE turnover in prefrontal cortex and hypothalamus. The present findings indicate that glyphosate significantly altered central nervous system (CNS) monoaminergic neurotransmitters in a brain regional- and dose-related manner.

I. MATERIALS AND METHODS

Chemicals; Glyphosate [N-(phosphonomethyl) glycine], molecular formula $C_3H_8NO_5P$ CAS RN 107-83-6, purity ≥ 98 %, serotonin (5-HT) and its metabolite [5-hydroxy-3-indolacetic acid (5-HIAA)], dopamine (DA) and its metabolites [3,4-hydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA)] and norepinephrine (NE) and its metabolite [3-metoxy-4-hydroxyphenylethyleneglycol (MHPG)] were purchased from Sigma-Aldrich, St Louis, MO, 63103 USA. All other chemicals were of the highest quality grade and obtained from commercial sources.

Animals and experimental design; All experiments using live animals were undertaken in accordance with the ethics requirements and authorized (protocol number 086) by the official ethical committee of our university. Male Wistar rats of 60 days old each weighing 200–210 g (Charles River Inc., Margate, Kent, UK) were used. The animals were individually housed in polycarbonate cages with sawdust bedding and maintained in environmentally controlled rooms (22 ± 2°C and 50 ± 10 % relative humidity) with a 12 h

light/dark cycle (light from 08.00 to 20.00 h). Food (A04 rodent diet, Scientific Animal Food & Engineering, SAFE, Augy, France) and water were available *ad libitum*. Thirty male rats were assigned randomly to five groups of 6 animals each, a control group and four glyphosate treated groups. Animal treated groups received glyphosate orally at the dose of 35, 75, 150 and 800 mg/kg bw [equivalent to 1/160, 1/75, 1/37 and 1/7 of the acute oral rat LD50 ≈ 5.6 g/kg bw] for 6 consecutive days. The doses were chosen taking into account the LD50 oral value as well as the NOAEL (no observed adverse effect level) described in the literature. The glyphosate treated group rats were deprived of food for 6 h before the oral administration of glyphosate, but were allowed water ad libitum. Glyphosate was dissolved in water and was administered orally by gavage in a maximum volume of 2 mL/rat. Control animals received the vehicle (water) on the same schedules. The animal body weights were measured during the study and food and water consumption of each animal was also assessed. The animals received the treatment at the same time each day, specifically between 10:00 and 11.00 a.m. Three hours after the last dose, the animals were sacrificed by decapitation. The brain was removed quickly and hypothalamus, midbrain, hippocampus, striatum and prefrontal cortex tissues rapidly dissected out at 4 °C. Tissues were rapidly weighed and stored at -80 °C until analysis.

Determination of monoamine levels; The five brain regions analysed in the present study were hypothalamus, midbrain, hippocampus, striatum and prefrontal cortex. Following sample collections, 300–800 µL of 0.4 M $HClO_4$ containing 0.1 % (w/v) $Na_2S_2O_5$ was added to the tissues, and the mixture was homogenized (1 min) by sonication (Labsonic U-Braun). The homogenates were centrifuged (RC5C, Sorvall Instruments) at 12,000g for 20 min at 4 °C and aliquots of supernatants were taken for analysis of 5-HT and its metabolite 5-HIAA, DA and its metabolites DOPAC and HVA and NE, using a high performance liquid chromatography (HPLC) technique with electrochemical detection. Also, aliquots of supernatants were taken for analysis of the norepinephrine metabolite MHPG by HPLC with fluorimetric detection. An acid-catalysed procedure was used to hydrolyse MHPG-sulphate in homogenates of brain region tissues. Volumes of 200–300 µL of the supernatants (in 0.4 M $HClO_4$) were treated for 3 min at 100 °C in a water bath. The samples were then cooled and 30 – 45 µL of 2 M NaOH were added (final pH: ca. 1.5) and aliquots were injected into a reverse phase HPLC system. For the analysis of catecholamines NE, DA, DOPAC and HVA, the mobile phase consisted of 0.1 M $Na_2HPO_4 \cdot 2H_2O$, 0.1 M citric acid (pH 3.5), 1.6 mM octane sulphonic acid, 0.9 mM EDTA and 10 % (v/v) methanol. For the analysis of the indolalkylamines 5-HT and 5-HIAA, the mobile phase consisted of 0.1 M $Na_2HPO_4 \cdot 2H_2O$, 0.1 M citric acid (pH 3.5) and 10 % (v/v) methanol. Elution was performed at a flow rate of 1 mL/min and the working electrode potential was set at 0.8 V for catecholamines and 0.7 V for indolalkylamines. The HPLC system consisted of a Shimadzu liquid chromatograph, model LC-9A equipped with a 5 µm particle size C18-Nucleosil reversed phase column (4 mm i.d. × 125 mm) proceeded by a C18 pre-column, an electrochemical detector (Shimadzu, model L-ECD-6A), a sample injector (20 µL valve) and an integrator (Shimadzu, model C-R6A Chromatopac). For the analysis of the norepinephrine metabolite (MHPG), the mobile phase consisted of 0.06 M $Na_2HPO_4 \cdot 2H_2O$, 0.03 M citric acid and 6 % (v/v) methanol. Elution was performed at a flow rate of 1.5 mL/min. The HPLC system consisted of a Shimadzu liquid chromatograph, model LC-10AS, a 25 µm particle size Tracer Extrasil ODS reversed phase column (4 mm i.d. × 125 mm), a fluorescence detector (Shimadzu, model RF-551), a sample injector (20 µL valve) and an integrator (Shimadzu, model C-R6A Chromatopac). Excitation and emission wavelengths of the detector were 275 and 315 nm, respectively. Peak areas from the sample chromatograms were used to quantify the analytes by external standard technique using solutions of catecholamines (NE, DA, DOPAC y HVA), indolalkylamines (5-HT and 5-HIAA) and norepinephrine metabolite (MPHG) reference standards (Sigma Chemical Co., St Louis, MO, USA). For tissue specimens as determined by use of a linear least squares regression procedure, a linear relationship existed in the calibration curve of catecholamines (NE, DA, DOPAC, HVA), indolalkylamines (5-HT, 5-HIAA) and norepinephrine metabolite (MPHG) over the range of 0.002–100 µg/g, which always yielded a correlation coefficient exceeding 0.9998. Overall mean recovery of catecholamines (NE, DA, DOPAC and HVA), indolalkylamines (5-HT and 5-HIAA) and norepinephrine metabolite (MPHG) from tissues was 100 % for every analyte. Within- and between-day variation was < 4 %. Quantification limit (LOQ) was 2 ng/g for NE, DA, DOPAC, 5-HT and 5-HIAA and 10 ng/g for HVA and MPHG in the different tissue matrices. NE, DA and 5-HT turnover were calculated as ratios of metabolites to neurotransmitter.

Data analysis; Statistical analysis of data was performed using GraphPad Prism 6 for Windows. Results

are presented as mean ± S.D. of 6 animals per group. Results significantly different from controls are also presented as percentage change over control. One-way ANOVA was carried out to determine significant dose-dependent effect of glyphosate on 5-HT, DA, NE and metabolite levels and the corresponding turnover values in the brain regions studied, followed by Tukey's post hoc test. Statistical significance was set at $P < 0.05$. ANOVA's F values are presented in the Tables. F distribution was calculated with numerator degrees (DFn) and denominator degrees of freedom (DFd).

II. RESULTS

The glyphosate-treated rats at oral doses of 35, 75, 150 and 800 mg/kg bw/day for 6 days had no visible injury. These doses were selected based on preliminary experiments where the doses and route of administration did not show any adverse effects, abnormal clinical signs as well as changes in body weight, food and water consumption in the animals (see table below).

Table 5.7- 2: Effect of glyphosate on body weight gain and food and water consumption in male rats

Parameter	Animal groups				
	Control	Glyphosate (35 mg/kg bw, 6 days)	Glyphosate (75 mg/kg bw, 6 days)	Glyphosate (150 mg/kg bw, 6 days)	Glyphosate (800 mg/kg bw, 6 days)
Body weight gain (g)	29.17 ± 2.64	27.67 ± 4.23	29.33 ± 3.08	30.00 ± 4.00	27.33 ± 4.50
Food consumption (g)	96.33 ± 7.45	98.00 ± 7.27	95.66 ± 7.39	93.67 ± 9.24	95.50 ± 9.05
Water consumption (mL)	133.83 ± 20.92	131.50 ± 20.12	129.5 ± 21.50	140.50 ± 24.77	151.00 ± 9.19

Results are presented as means ± SD for six rats.
Results are not significantly different from control group.
Continuous probability distribution (F) for all parameters were lower than 1.140 (DFn = 4, DFd = 25).

All the rat groups exposed to glyphosate by oral route did not show statistically difference on weight of tissues (brain regions) or the ratio weight tissue/body weight (%) compared to control group (data not shown). Glyphosate at a dose of 35 mg/kg bw did not affect the 5-HT, DA, NE and metabolite levels in the brain regions studied. In this study, 35 mg/kg bw might be identified as the NOAEL based on neurotransmitter changes in CNS. Glyphosate at doses of 75, 150 and 800 mg/kg bw produced in a dose-dependent manner a significant decrease of 5-HT content respect to control in striatum. Moreover, glyphosate at doses of 150 and 800 mg/kg bw produced a significant decrease of 5-HT content respect to control in hippocampus and prefrontal cortex and only at a dose of 800 mg/kg bw in hypothalamus and midbrain. In addition, the highest dose (800 mg/kg bw) of glyphosate resulted in a significant decrease in the 5-HIAA levels in hippocampus compared to control group. Also, glyphosate at doses of 150 and 800 mg/kg bw significantly increased the turnover (5-HIAA/5-HT) in striatum and hypothalamus compared to control groups (see table below).

Table 5.7- 3: Effect of glyphosate on 5-HT and 5-HIAA levels and turnover (5-HIAA/5-HT) in brain regions of male rats

With respect to DA, DOPAC and HVA levels and turnover in brain regions (see table below), glyphosate at doses of 75, 150 and 800 mg/kg bw produced, in a dose-dependent manner, a statistically significant decrease of DA levels in prefrontal cortex and midbrain compared to control groups. Likewise, glyphosate at the highest dose (800 mg/kg bw) decreased significantly the DA levels in hypothalamus, striatum and hippocampus compared to control group. Moreover, glyphosate at doses of 150 and 800 mg/kg bw decreased significantly the DOPAC metabolite levels in hypothalamus and glyphosate at highest dose only produced a significant decrease of DOPAC levels in hippocampus respect to control group. In addition, the HVA levels significantly decreased after doses of glyphosate 75, 150 and 800 mg/kg bw in hypothalamus, after doses of glyphosate 150 and 800 mg/kg bw in midbrain; and after dose of 800 mg/kg bw in prefrontal cortex respect to control groups. Glyphosate (75, 150 and 800 mg/kg bw) produced a significant increase of the turnover (DOPAC+HVA/DA) in prefrontal cortex respect to control groups. Glyphosate at highest dose only produced a significant increase of the turnover (DOPAC+HVA/DA) in hippocampus (see table below).

In relation to NE and MHPG levels and turnover, glyphosate at doses of 75, 150 and 800 mg/kg bw produced a significant decrease of the NE levels in striatum and midbrain compared to control. Moreover, glyphosate at doses of 150 and 800 mg/kg bw produced a significant decrease of NE levels in hippocampus

and only at a dose of 800 mg/kg bw in prefrontal cortex respect to control groups. Moreover, MHPG levels significantly decreased after doses of glyphosate 150 and 800 mg/kg bw in hippocampus and after dose of glyphosate 800 mg/kg bw in striatum, prefrontal cortex, hypothalamus and midbrain. Glyphosate at dose of 800 mg/kg bw produced a significant decrease of the turnover (MHPG/NE) in prefrontal cortex and hypothalamus compared to control group (see table below).

Table 5.7- 5: Effect of glyphosate on NE and MHPG levels and turnover (MHPG/NE) in brain regions of male rats

Discussion

Pesticides are widely used in agricultural and other settings, resulting in continuing human exposure. The nervous system represents a prime target for both the acute and chronic effects of pesticides. Among them are the organochlorines, pyrethroids, organophosphates, neonicotinoids, herbicides and some novel agents. Acute symptoms can include headache, nausea, dizziness, and sensory paraesthesia. Toxicity often involves neuronal hyper-excitability, and disorders of cognition. Toxicological in vitro and in vivo studies have demonstrated specific neurodegenerative effects from exposure to certain pesticides, and human case reports have suggested a causal relationship between certain pesticide exposures and Parkinson's disease (PD) typically associated with degeneration of the dopaminergic neurons. Evidence is also now accumulating that organophosphate pesticides target serotonin and noradrenergic systems contributing to adverse outcomes related to emotional and social behaviours. Ingestion of the herbicide glyphosate may cause significant toxicity including nausea, vomiting, diarrhea, oral and abdominal pain, renal and hepatic impairment, and pulmonary oedema. Impaired consciousness and seizures have also been reported as sequelae but there are limited data of glyphosate on central nervous system (CNS) toxicity. This study was designed to investigate the effects of glyphosate on CNS monoaminergic neurotransmitter contents (5-HT, DA and NE) in male Wistar rats in order to generate more data on the glyphosate neurotoxicity. The current study showed that exposure to glyphosate, in a region and dose-dependent manner, was accompanied by a significant decrease in the 5-HT, DA and NE contents in the brain regions studied (striatum, hippocampus, prefrontal cortex, hypothalamus, hypothalamus and midbrain), which indicated that glyphosate transfer across the blood-brain barrier, enters the brain, probably accumulates in significant quantity, and exerts neurotoxicity altering the serotonergic, dopaminergic and noradrenergic systems. Researchers have reported similar changes of these brain neurotransmitters after exposure to the insecticide pyrethroid cyfluthrin. It should be noted that the rats treated with glyphosate at dose of 35 mg/kg bw per day did not exhibit any effects on the 5-HT, DA and NE contents in the brain regions studied. In our study, this NOAEL

observed (35 mg/kg bw per day) was lowest to that identified on the maternal and developmental toxicity studies (NOAEL of 50 mg/kg bw per day) and used to establish the ADI. For current regulatory evaluation of risks associated with glyphosate exposure, a NOAEL of 35 mg/kg bw per day could be used instead of a NOAEL of 50 mg/kg bw per day. In this regard, taking into account that glyphosate probably accumulates in the CNS and considering that in the present study the glyphosate exposure was only during only 6 days, further research with a longer period of exposure should be necessary to corroborate the proposed NOAEL of 35 mg/kg bw per day. In the present study, quantitative analysis of 5-HT, DA and NE contents showed that the loss of these neurotransmitters was mainly observed in the striatum [5-HT and NE contents decreased significantly (-49 % and -51 %, respectively) after the highest dose of 800 mg glyphosate/kg bw] and in prefrontal cortex and hippocampus [DA contents decreased significantly (-83 % and -71 %, respectively) after the highest dose of 800 mg glyphosate/kg bw]. Previously, Researchers also showed in rats that glyphosate decreased DA but not 5-HT levels in striatum as well as reduced the locomotor activity suggesting that the decrease in striatal DA levels could also explain a behavioural hypoactivity. Moreover, in our study, glyphosate after the highest dose of 800 mg/kg bw produced a significant increase of the (5-HIAA/5-HT) turnover in striatum (88 %) and of the (DOPAC+HVA/DA) turnover in prefrontal (153 %) and hippocampus (150 %), but a significant decrease of the (NE/MHPG) turnover in prefrontal cortex (-23 %) and hypothalamus (-55 %), critical brain regions that regulate cognitive functions. The cooperation of the hippocampus and the prefrontal cortex is vital in spatial working memory performance and decision making. Disconnection or damage to either of the two brain regions induces impaired cognitive behaviours. Because cognitive functions are quite complex, more details are required for the complete understanding of glyphosate-induced neurotoxicity. It would be of interest to investigate the developmental changes of the hippocampus and prefrontal cortex in prenatal glyphosate.

III. CONCLUSION

In conclusion, the results demonstrate that glyphosate leads to loss of 5-HT, DA and NE levels in the CNS. The neurochemical effects observed in the present study are an important public health concern. Although we have no data on humans, glyphosate could exert its neurotoxicity, notably on monoamine systems, by inducing DNA damage, neuronal inflammation and oxidative stress mechanisms. Further investigation is needed to involve the glyphosate herbicide with neurodegenerative diseases.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Although the study concludes "loss of 5-HT, DA and NE levels in the CNS", no historical controls are available to assess and compare the changes in the treatment-groups to ascertain if the effects are within background or if they are biologically relevant.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because there were no negative or positive historical control data to establish whether changes in the levels of neurotransmitters were biologically meaningful. No concurrent positive control was included to demonstrate assay viability. Also no analytical verification of dose levels are available.

Assessment and conclusion by RMS:

Reliability criteria for *in vivo* toxicology studies

Report title	Specific pesticide-dependent increases in α-synuclein levels in human neuroblastoma (SH-SY5Y) and melanoma (SK-MEL-2) cell lines.
Document No	doi:10.1093/toxsci/kft076 E-ISSN: 1096-0929.
Guidelines followed in study	None
Deviations from current test guideline	Not applicable
Previous evaluation	Yes, evaluated in RAR (2015)
GLP/Officially recognised testing facilities	No, not conducted under GLP/Officially recognised testing facilities
Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

The objective was to precisely assess changes in α-syn levels in human neuroblastoma (SH-SY5Y) and melanoma (SK-MEL-2) cell lines following acute exposure to glyphosate using Western blot and flow cytometry. The study was conducted using an in vitro test system. Glyphosate did not have any impact on the endpoints measured in this study.

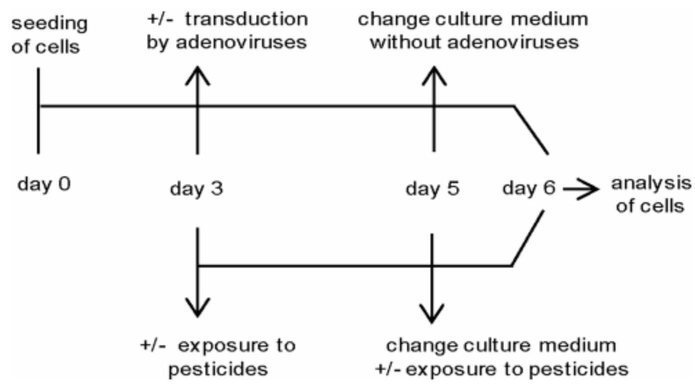
I. MATERIALS AND METHODS

Cell culture: SH-SY5Y (a human dopaminergic neuroblastoma cell line) and SK-MEL-2 (a human cutaneous melanoma cell line) obtained from American Type Culture Collection (ATCC, Rockville, MD) were maintained in Dulbecco's modified Eagle's (DMEM-F12-GlutamaxI) medium containing 10 % fetal bovine serum (Invitrogen), 100 U/mL penicillin, and 100 µg/mL streptomycin in an incubator at 37 °C and 5 % CO2.

Recombinant AdV-mediated overexpression of α-syn. Cell transduction was performed as previously described (see study report). Briefly, a recombinant adenoviral genome containing the full-length complementary DNA encoding human WT and mutant A53T α-syn in frame with a C-terminal myc-His epitope tag was generated by homologous recombination. Cells were infected with α-syn AdV or GFP AdV. On day 2 of infection, the medium was replaced with AdV-free DMEM.

Pesticides exposure: Cells at 70 % confluence were exposed to glyphosate (N-(phosphonomethyl)-glycine) (Sigma-Aldrich). Purity was 99.5 %. Glyphosate was dissolved in ultrapure water. Glyphosate concentrations for cell exposures (at 75 and 50 % viability) were chosen based on the evaluation of toxicity following exposure of the SH-SY5Y cell line (0.005-800 µM) using the 3-(3,4-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. The protocol used for cell exposure and / or transduction with recombinant AdVs is shown in the figure below.

Figure 5.7-1: Experimental protocol of exposure to pesticides and recombinant AdV transduction of SH-SY5Y neuroblastoma and SK-MEL-2 melanoma cell lines.



At approximately 70 % cell confluence (day 3), cells were transduced with recombinant AdVs for protein overexpression (WT α-syn, A53T α-syn, GFP) and/or exposed to pesticides (rotenone, paraquat, maneb, and glyphosate) at concentrations corresponding to the IC50 determined on the SH-SY5Y cell line. For certain experiments, these two steps (pesticides exposure/adenoviral transduction) were combined. After 48 h (day 5), two protocols were followed. When the cells were only transduced with AdV, the culture medium was replaced by fresh AdV-free culture medium. When the cells were exposed to pesticides, the culture medium was replaced by fresh AdV-free culture medium supplemented with pesticides. Experiments were ended 24 h later (day 6), and adherent cells were collected for analyses by flow cytometry or Western blot.

Cell death and viability assays: The MTT assay was performed with the Celltiter96 nonradioactive kit (Promega, France). MTT is metabolically converted into formazan by mitochondrial dehydrogenases of healthy, living cells. Briefly, 5 × 10^4 cells per well were seeded into 96-well plates in duplicate and then treated with different concentrations of glyphosate. Cell death was assessed after 72 h of pesticide exposure. Then, 15 µL of "dye solution" was added to each well, and the plates were incubated at 37 °C, 5 % CO_2, for 4 h. Finally, 100 µL of "solubilization/stop solution" was added. After incubation for 1 h at 37 °C, the optical density of the dissolved formazan grains within the cells was measured spectrophotometrically at 560 nm (BioTek ELx808, France). Results were expressed as percentage of the control. The IC_{50}, half-maximal (50 %) inhibitory concentration, was determined for each pesticide from the graph of cell viability.

Protein extraction and Western blotting: After pesticide exposure, the cells were harvested and lysed in Laemmli buffer and then heated for 10 min at 100 °C. The cell extract was then centrifuged (15,000 × g, 30 min at 4 °C) before being loaded on to 12 % gel for SDS-PAGE. Western blots were performed as previously described (see study report). Blots were hybridized with monoclonal antibodies against β-actin (Abcam, dilution 1:1000) and against α-syn (clone 42, BD Biosciences, dilution 1:2000) overnight at 4 °C. The membranes were then washed and further hybridized with goat anti-mouse immunoglobulin G (IgG) horseradish peroxidase–conjugated antibody (Pierce, dilution 1:1000) for 30 min at room temperature. Protein bands were detected with chemiluminescent reagents (SuperSignal West Dura Extended Duration Substrate Kit, Pierce), then exposed to autoradiographic films or to a CCD camera (Versadoc system 5000, Bio-Rad), and quantified by Quantity One soft- ware (Bio-rad).

Flow cytometry: The cells were harvested by centrifugation at 1000 × g for 5 min at 4 °C. The cell pellets were resuspended in a blocking solution (2 % BSA-PBS) at 4 °C. The cells were simultaneously permeabilized and fixed for 20 min at 4 °C with BD Cytofix/Cytoperm Kit (BD Biosciences). All steps were carried out with permwash solution (BD Permwash Kit). After another centrifugation step, the cell pellets were incubated with α-syn clone 42 antibody in permwash solution for 30 min at 4 °C. They were then rinsed with permwash solution and incubated with goat anti-mouse IgG R-phycoerythrin conjugate (Invitrogen) at 4 °C for 30 min. The specific fluorescence intensities were measured with a BD FACS LSRII analyzer (BD Biosciences). Data were acquired using Diva software (BD Biosciences) and analyzed with FlowJo software (v7.6.5-TreeStar, Ashland, Oregon).

Statistical analysis: The results represent means ± SEM from at least 3 and up to 15 independent

experiments. The effects of glyphosate on cell survival, following exposures of the four cell types (SH-SY5Y ± WT α-syn AdV and ± A53T α-syn AdV and ± GFP AdV) to different concentrations, were determined from an analysis of covariance. The results from Western blot studies were subjected to a Wilcoxon's test. For the flow cytometry studies of AdV-transduced cells, the mean fluorescence intensities of cells exposed or not exposed to glyphosate were compared using Student's test. Then, we realized a Levene's analysis in order to verify the hypothesis of homogeneity of variances. If the hypothesis was not verified, the Welch's analysis was used.

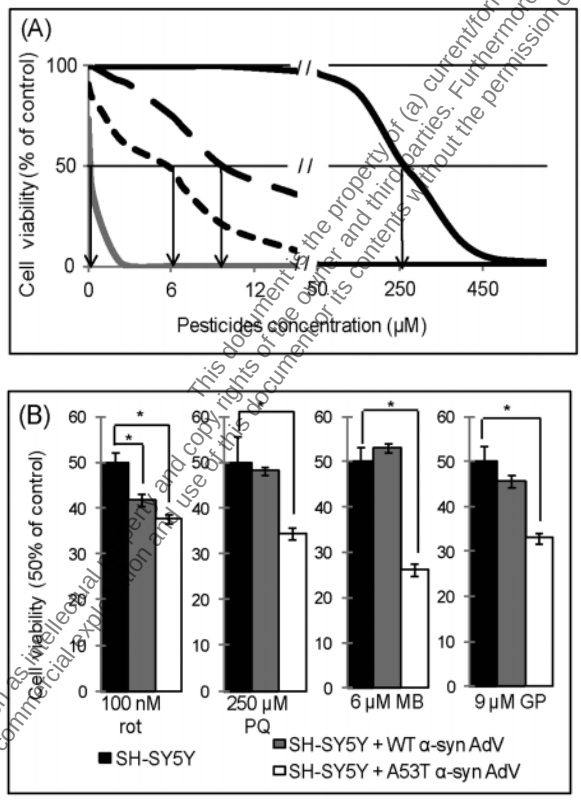
II. RESULTS

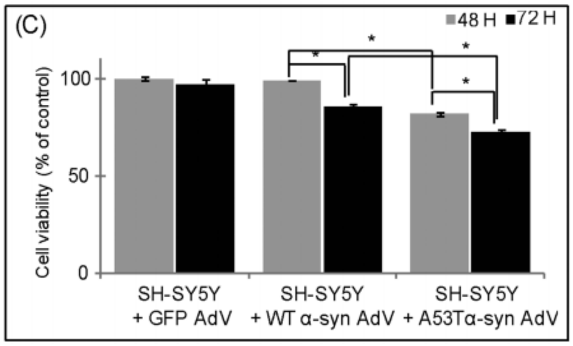
The impact of in vitro exposure to glyphosate on α-syn levels was assessed in two human cell lines of neuronal (SH-SY5Y) or melanocytic (SK-MEL-2) origin. The levels of endogenous α-syn or of recombinant α-syn levels after transduction with recombinant AdVs (WT and A53T α-syn AdV) were analyzed by Western blot and flow cytometry.

Cytotoxicity Associated With Pesticide Exposure and/or Adenoviral Transduction

The SH-SY5Y neuronal cell line was first exposed to various concentrations of glyphosate (0.005-800 µM) for 72 h. The respective cytotoxicity of glyphosate (relative amounts of living and metabolically active cells) was estimated by MTT assay (see figure below). This showed that glyphosate had a distinct effect on the survival of SH-SY5Y cells after 72 h of exposure. The half-maximal (50 %) inhibitory concentrations (IC50) for glyphosate was 9 µM. It was 11 µM for glyphosate for the SK-MEL-2 cell line. The IC50 value, determined after exposure of the SH-SY5Y cell line for 72 h, was chosen for further investigations of the effects on α-syn levels. The same concentration was used in experiments with the SK-MEL-2 melanoma cell line.

Figure 5.7- 2: Effects of pesticides and adenoviral transduction on viability of SH-SY5Y neuroblastoma cells.





(A) Cell viability was assessed using the MTT assay. Data represent mean ± SEM numbers of viable treated cells/numbers of viable untreated cells from three separate experiments (*$p < 0.05$). The p values were determined by Wald's test. The cell viability percentage after 72-h treatment with increasing concentrations (0.005-800 µM) of pesticide was measured: rotenone (grey curve), maneb (dashed black curve), glyphosate (black curve em dash), or paraquat (black solid curve).

(B) Part of the concentration range has been removed to facilitate comparison of the results. We then used the IC_{50} previously determined on SH-SY5Y cells (100 nM and 6, 9, and 250 µM) to quantify the viability of cells transduced with WT or A53T α-syn AdV after pesticide exposure for 72 h in comparison to untransduced SH-SY5Y cells.

(C) The cytotoxicities associated with the recombinant Advs transduction alone, with either the GFP protein, WT or A53T α-syn AdV, were measured at 48 h (grey bars) and 72 h (black bars).

Glyphosate cytotoxicity, following exposure for 72 h of SH-SY5Y cells transduced with recombinant AdVs, was then analyzed using the protocol summarized in Figure 5.7-1. The MTT assay did not reveal a significant decrease in the viability of WT α- syn AdV-transduced cells after exposure to glyphosate [-2 % [$p = 0.6$]) at the previously determined IC50 (see Figure 5.7-2 (B)). Viability was significantly decreased (-17 %) with glyphosate ($p < 0.01$) when the cells were transduced with A53T α-syn AdV. Thus, glyphosate induced a greater reduction of viability in cells transduced with A53T α-syn AdV than in nontransduced SH-SY5Y cells.

It should be noted, however, that viability was also consistently decreased in the absence of pesticide exposure, after transduction with WT α-syn AdV (-14 %)($p < 0.05$) and even more so with A53T α-syn AdV (-38 %)($p < 0.05$) at 72 h, as shown in Figure 5.7-2 (C) representing three different experiments. Viability was already decreased 48 h after transduction with A53T α-syn AdV (-18 %) ($p < 0.05$). Cytotoxicity seemed to be related to α-syn overexpression, as viability was unchanged 48 or 72 h after transduction with the GFP AdV used as a control in these experiments.

Specific Increase of Endogenous α-syn in Human Neuroblastoma and Melanoma Cells Exposed to Pesticides

Both SH-SY5Y neuroblastoma and SK-MEL-2 melanoma cell lines express α-syn. We therefore assessed endogenous α-syn expression using Western blot and flow cytometry and examined the ability of glyphosate exposure to modulate changes in α-syn levels. The Western blot experiments indicated that endogenous α-syn levels (**Error! Reference source not found.** A) were significantly increased by 100 nM rotenone (~1.81×) ($p < 0.001$), whereas no change was observed in the closely related, but nonamyloidogenic, β-synuclein protein **Error! Reference source not found.** C). The impacts of glyphosate on the level of endogenous α-syn in SH-SY5Y neuroblastoma cells was measured in comparison (**Error! Reference source not found.** A). A significant increase in α-syn levels was not observed with glyphosate up to 9 µM ($p = 0.6553$).

Quantification of Recombinant α-Syn Levels by Flow Cytometry Following Pesticide Exposure

We then attempted to quantify the changes in α-syn levels following transduction with AdV designed to overexpress α- syn. Transduction of SH-SY5Y cells with WT or A53T α-syn AdV resulted in similar levels of α-syn expression as measured by flow cytometry. In comparison to the isotype control, a 5.1 % increase

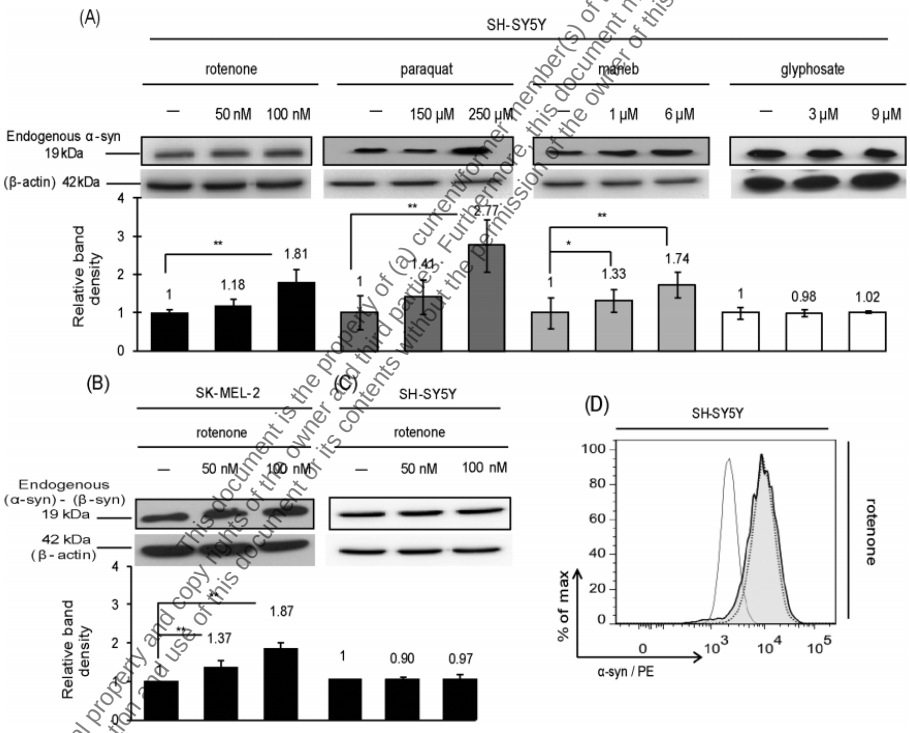
in fluorescence intensity was observed compared with 1.7 % for the endogenous protein. Similar levels of α-syn were produced in α-syn AdV-transduced SK-MEL-2 cells (data not shown). The Western blot revealed that transduction with recombinant α-syn AdV was associated with a predominant band at 22.5 kDa, resulting from the presence of the myc-His tag epitope, in addition to the 19 kDa band representing the endogenous α-syn.

We then confirmed the effects of pesticides on AdV-associated α-syn levels by Western blot. In AdV-transduced SH-SY5Y cells, 1.38- and 1.70-fold increases were observed with WT (left panel) and A53T (right panel) α-syn, respectively, following exposure to 100 nM rotenone ($p < 0.001$).

Pesticide impact was then assessed by flow cytometry after 72-h exposure of SH-SY5Y cells transduced with WT or A53T α-syn AdV to the IC_{50} (determined on the SH-SY5Y cell line) in comparison to a GFP AdV control. The observed increases in α-syn levels were specific, as no change in GFP fluorescence was apparent after exposure to glyphosate (data not shown) of cells transduced with a GFP AdV control.
No increase in α-syn levels was detected after exposure of SH-SY5Y cells transduced with WT or A53T α-syn AdV to glyphosate.

No significant increase in α-syn levels was found after the exposure to glyphosate of SK-MEL-2 cells transduced with WT or A53T α-syn AdV (compared with those transduced with GFP AdV).

Figure 5.7- 3: Characterization of the impact of pesticides on endogenous α-syn levels in SH-SY5Y and SK-MEL-2 cells by Western blot and flow cytometry.



(A) The levels of endogenous α-syn were estimated by Western blot after exposure of SH-SY5Y cells to different pesticides at concentrations corresponding to 25 and 50 % of the IC_{50} (50 and 100 nM rotenone; 150 and 250 µM paraquat; 1 and 6 µM maneb; 3 and 9 µM glyphosate).

(B) Similarly, the levels of endogenous α-syn in SK-MEL-2 cells exposed to 50 and 100 nM rotenone were also assessed.

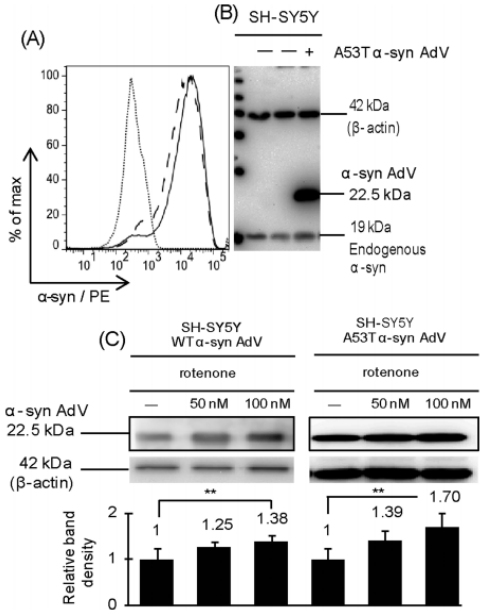
(C) In parallel, we estimated the amounts of β-synuclein in SH-SY5Y cells after rotenone exposure.

(D) β-actin was used as a loading control. Data represent the means ± SEM from four to six independent experiments obtained by Wilcoxon's test (**$p < 0.001$; *$p < 0.05$). The fold increase is indicated above the histogram for each experimental condition. Finally, the fluorescence curves corresponding to the levels of endogenous α-syn (dotted curve) in SH-SY5Y cells observed by

flow cytometry after exposure to 100 nM rotenone (black curve, shaded area) are compared with SH-SY5Y cells immunostained with an isotype control (grey curve)(D).

Data represent the means ± SEM from three independent experiments.

Figure 5.7- 4: Characterization of the impact of pesticides on recombinant α-syn levels in SH-SY5Y cells by Western blot and flow cytometry.



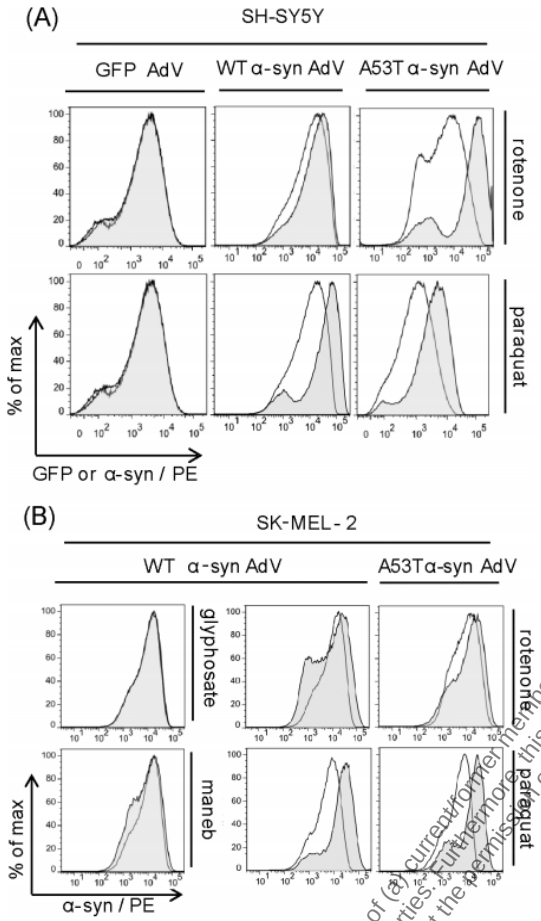
(A)Three days after adenoviral transductions, the cells were permeabilized and immunostained with clone 42 antibody raised against α-syn. The flow cytometry histogram shows the levels of recombinant α-syn in SH-SY5Y cells overexpressing either WT (dashed line) or A53T (solid line) α-syn AdV, in comparison to endogenous α-syn (grey line).

(B) Western blot detection of recombinant α-syn in comparison to endogenous α-syn is shown.

(C) Finally, the levels of recombinant α-syn were quantified in SH-SY5Y cells transduced with either WT or A53T α-syn AdV following rotenone exposure at 50 and 100nM.

Data represent the mean ± SEM α-syn/β-actin ratios from four independent experiments (**$p < 0.001$ obtained by Wilcoxon's test).

Figure 5.7- 5: Characterization of the impact of pesticides on α-syn levels in AdV-transduced SH-SY5Y and SK-MEL-2 cells by flow cytometry.



(A) Fluorescence curves correspond to the α-syn levels following AdV transduction of SH-SY5Y cells by GFP AdV (left column, solid curve not shaded), WT α-syn AdV (center column, solid curve not shaded), and A53T α-syn AdV (right column, solid curve not shaded) alone or following exposure to either 100nM rotenone (upper panel, solid curve, grey shaded) or 250µM paraquat (lower panel, solid curve, grey shaded).

(B) Fluorescence curves correspond to the α-syn levels in SK-MEL-2 after transduction with WT α-syn AdV (left and center column, solid curve not shaded) or A53T α-syn AdV (right column, solid curve not shaded) alone or following exposure to 9µM glyphosate (solid curve, grey shaded), 6µM maneb (solid curve, grey shaded), 100nM rotenone (upper panel, solid curve, grey shaded), or 250µM paraquat (lower panel, solid curve, grey shaded).

Data represent the means ± SEM of 6 to 12 separate experiments for each of the different pesticide exposures.

III. DISCUSSION & CONCLUSION

Overall, the specific effects of the pesticides were quite consistent for both endogenous and AdV-produced α-syn. The mechanisms involved in the pesticide-induced increases were not examined but could reflect a decreased efficiency of the cellular mechanisms involved in the degradation of misfolded proteins such as the proteasome pathway, and/or, for the endogenous protein, increased synthesis of the protein. The changes in protein levels were specific to α-syn, as no changes were observed for a GFP protein encoded by recombinant AdVs or for the endogenous β-synuclein expressed in the SH-SY5Y cell line. β-Synuclein shares a high homology sequence with α-syn but is less prone to aggregation in relation with the absence of 11 amino acids in the central region of the protein.

No effect of the pesticide glyphosate on α-syn levels was detected. Although a case of parkinsonian

syndrome was reported following acute poisoning with glyphosate, it was concluded in a new study that there is little evidence to suggest a causal relationship between glyphosate exposure and noncancer diseases, including PD.

It was found that paraquat, and to a lesser extent rotenone, but not maneb or glyphosate, also increased the α-syn levels in SK-MEL-2 cells, whether produced endogenously or after adenoviral transduction. In summary, we provide an approach based on commonly used methods, which allow the quantification of cellular α-syn levels, and we show here that these levels are greatly increased following exposure to certain pesticides, which have been specifically associated with PD. This experimental strategy could provide useful and readily available information specific to each pesticide so that the neurotoxic potential of the chemical can be assessed prior to large scale use in the field. On this basis, further studies are now focusing on the development of analytical methods in microplate format, which would be more convenient for large scale screening. To what extent such in vitro observations reflect specific events involved in the molecular pathogenesis of human α-syn associated diseases remains to be determined.

1. Assessment and conclusion

Assessment and conclusion by applicant:

The objective was to precisely assess changes in α-syn levels in human neuroblastoma (SH-SY5Y) and melanoma (SK-MEL-2) cell lines following acute exposure to glyphosate using Western blot and flow cytometry. The study was conducted using an *in vitro* test system. Glyphosate did not have any impact on the endpoints measured in this study. This is not a guideline study, nor did this study evaluate an endpoint used in risk assessment. Therefore, this study in not usable for quantitative human health risk assessment or hazard assessment.

This publication is considered reliable with restrictions (no positive control was included and only 2 test concentrations were used) but is not relevant for the risk assessment of glyphosate.

Assessment and conclusion by RMS:

Reliability criteria for *in vitro* toxicology studies

Publication: Chorfa *et al.*, 2013	Criteria met? Y/N/?	Comments
Guideline-specific		
Study in accordance to valid internationally accepted testing guidelines	N	
Study performed according to GLP	N	
Study completely described and conducted following scientifically acceptable standards	Y	
Test substance		
Test material (Glyphosate) is sufficiently documented and reported (i.e. purity, source, content, storage conditions)	Y	Purity of 99.5 %. Source: Sigma-Aldrich.
Only glyphosate acid or one of its salts is the tested substance	N	Also other pesticides tested (rotenone, paraquat, maneb).
AMPA is the tested substance	N	
Study		

Test system clearly and completely described	Y	Human neuroblastoma (SH-SY5Y) and melanoma (SK-MEL-2) cell lines.
Test conditions clearly and completely described	Y	
Metabolic activation system clearly and completely described	NA	
Test concentrations in physiologically acceptable range (< 1 mM)	Y	0, 3, and 9 µM.
Cytotoxicity tests reported	Y	
Positive and negative controls	N	No positive controls used.
Complete reporting of effects observed	Y	
Statistical methods described	Y	
Historical negative and positive control data reported	N	
Dose-effect relationship reported	Y	
Overall assessment		
Reliable without restrictions		
Reliable with restrictions	X	
Reliability not assignable		
Not reliable		
This publication is considered not relevant for the risk assessment of glyphosate because it is not a guideline study, nor did this study evaluate an endpoint used in risk assessment. It is reliable with restrictions because no positive control was included and only 2 test concentrations were used.		

CA 5.8 Toxicity studies of metabolites

CA 5.8.1 Toxicity studies of metabolites

Studies with AMPA

The metabolite aminomethyl phosphonic acid (AMPA) was investigated for metabolism/excretion, acute and subchronic toxicity, mutagenicity and teratogenicity. Overall the present studies show that AMPA has a lower toxicity than the parent compound glyphosate and is devoid of any mutagenic or teratogenic potential.

Absorption, Distribution, Metabolism and Excretion
A metabolism and excretion study in rats shows that AMPA is moderately absorbed from the gastrointestinal tract and excretion is rapidly and nearly complete. Main excretion route is *via* faeces (74 %). Approximately 20 % of the material is absorbed and most of that amount is rapidly excreted unchanged in the urine (13 % within 12h). Of the material absorbed, very small amounts are catabolized as evidenced by the facts that less than 0.1 % of the dose is expired in air and tissue residues are less than 10 ppb (Colvin, Moran & Miller, 1973, CA 5.8.1/001).

Acute toxicity
A total of five acute oral toxicity studies and two acute dermal toxicity studies are available. From the acute oral studies an oral LD_{50} of > 5000 mg/kg bw both in rats and mice was derived ([redacted] 1996, CA 5.8.1/002; [redacted], 1993, CA 5.8.1/003; [redacted], 1991, CA 5.8.1/004, [redacted] 1988, CA 5.8.1/005). Diarrhoea and general clinical signs of toxicity were observed at dose levels of 5000 mg/kg bw. An even higher LD50 was obtained one study in rats (LD50 of > 8300 mg/kg bw) based on mortality occurring in 1/5 rats at 6310 mg/kg bw, 2/5 at 7940 mg/kg bw and 4/5 at 10000 mg/kg bw ([redacted], 1973; CA 5.8.1/006). However, this study is considered to provide only supportive information as the reporting was very brief.

The dermal LD_{50} was found to be >2000 mg/kg bw for rats ([redacted], 2002, CA 5.8.1/007; [redacted], 1993, CA 5.8.1/008).

Studies assessing the skin and eye irritation of AMPA are available ([redacted], 1973, CA 5.8.1/009 and 010). No skin irritation potential was found, but a slight irritating effect in the eye comprising slight to moderate erythema was observed. However, it can be concluded that the test substance is not corrosive to the eye as all observations were reversible within 120 h. Since experimental procedures are described very briefly and no individual animal data are given, the study is considered as supportive only.

In two Magnusson and Kligman Maximisation Tests, no sensitising effects of AMPA were observed ([redacted], 2002, CA 5.8.1/011; [redacted], 1993, CA 5.8.1/012).

Short-term toxicity
The short-term toxicity of AMPA was investigated in rats and dogs.
In rats, a NOAEL of 400 mg/kg bw/day was derived from a 90-day study ([redacted], 1979, CA 5.8.1/017) based on decreased body weight gain/food consumption, gastrointestinal clinical signs and urogenital lesions (epithelial hyperplasia of bladder and renal pelvis) and concomitant increase in lactic dehydrogenase activity in blood at 1200 mg/kg bw/day. However, in a 13-week study in rats, no adverse effects were observed up to a dose of 1000 mg/kg bw/day, although lactic dehydrogenase activity was not determined in this study ([redacted], 1993, CA 5.8.1/016). In other rat studies of shorter duration, except for slight to moderate decreases in body weight gain in male rats when compared with control and a very slight decrease in food consumption at 4000 mg/kg bw in a 14-day dose range finding study (no histopathology findings) and a slight increase in kidney weights in male rats at 350 and 1000 mg/kg bw/day in a 4-week study no further adverse effects were detected ([redacted], 1978, CA 5.8.1/013; [redacted], 1993, CA 5.8.1/014).

In dogs, the most sensitive NOAEL was obtained from a 1-month study. Based on haemotology findings indicative for mild to moderate anaemia, a NOAEL of 300 mg/kg bw/day in males and 100 mg/kg bw/day in females was obtained ([redacted] 1991, CA 5.8.1/015). No further adverse effects were observed. In a 90-day study in dogs, no treatment related effects were observed up to a nominal highest dose of 300 mg/kg bw/day (263 mg/kg bw/day after adjustment for purity) neither in males nor females ([redacted], 1991, CA 5.8.1/018).

Genotoxicity
AMPA was tested negative for bacterial mutagenicity in four Ames tests and for mammalian cells mutagenicity in one Mouse lymphoma assay ([redacted], 1996, CA 5.8.1/019; [redacted] 1993, CA 5.8.1/020; [redacted], 1988, CA 5.8.1/021 and [redacted], 1980, CA 5.8.1/022; [redacted] 1993, CA 5.8.1/023). Further, in two *in vitro* UDS assays, AMPA did not induce unscheduled DNA synthesis in primary rat hepatocytes ([redacted], 2002, CA 5.8.1/024; [redacted], 1991, CA 5.8.1/025). However, both tests were considered to provide only supportive information, as the UDS assay is no longer a standard method described by current guidelines for this endpoint.

The clastogenic/aneugenic activity of AMPA was investigated in two *in vivo* micronucleus tests in mice. Both tests were negative for micronuclei after single administration of 5000 mg/kg bw or at doses of up to 1000 mg/kg bw, respectively ([redacted], 1993, CA 5.8.1/026; [redacted], 1993, CA 5.8.1/027).
In order to comply with the current OECD testing guidelines a set of 3 *in vitro* genotoxicity studies conducted according to the most recent guidance document requirements is currently being performed with AMPA (Ames test, HPRT test, micronucleus test in human lymphocytes).

However, the overall weight of evidence based on available data are that metabolites of glyphosate are non-genotoxic.

Developmental toxicity

Three developmental toxicity studies in rats are available.
The most sensitive NOAEL for maternal toxicity was 150 mg/kg bw/day based on clinical signs, decrease of bw gain and food consumption at 400 and 1000 mg/kg bw/day. Further, the NOAEL for developmental toxicity was 400 mg/kg bw/day based on decreased fetal weight ([redacted], 1991, CA 5.8.1/030). In the two other developmental studies, there was no evidence of toxicity in either the dam or embryo-fetal development at any of the dose levels applied (up to 1000 mg/kg bw/day) ([redacted], 1992, CA 5.8.1/028; [redacted], 1991, CA 5.8.1/029). No teratogenic effects were observed in any of the three studies.

Literature evaluation

In addition to studies commissioned by representatives of the Glyphosate Renewal Group, several publications identified from the open literature have been submitted.
One publication is available addressing the effects of AMPA (and further glyphosate, it´s metabolite methylphosphonic acid and some impurities) on apoptosis induction in human peripheral blood mononuclear cells (PBMCs) (Kwiatkowska *et al*, 2020, CA 5.8.1/031). All substances changed PBMCs membrane permeability, activated caspase-8, -9, -3 and caused chromatin condensation, which showed that they were capable of inducing apoptosis both via extrinsic and particularly intrinsic pathway at high concentrations only. Generally the study demonstrated that there were no differences between apoptotic changes induced by glyphosate, its metabolites or impurities, and observed changes were provoked by high concentrations of investigated compounds. Since clear changes were only seen at high concentrations, a low apoptotic potential of these compounds was concluded.

This publication was considered relevant for the risk assessment of AMPA but reliable with restrictions because no proper cytotoxicity tests were performed, no positive controls were used and the concentration range at which most of the effects were observed is beyond the acceptable physiological range (> 1 mM).

Mañas F. *et al.* (2020, CA 5.4/012) reported that AMPA did not have an effect on oxidative stress parameters in liver, kidney, lung and heart in a Comet assay in Balb C mice after 14-day exposure to AMPA via drinking water. A statistically significant increase in DNA damage parameters was observed for AMPA in blood and liver. Nevertheless, the increase of tail intensity was rather low (1.23- and 1.65-fold in blood and liver). No positive or historical control data were provided for further evaluation. In addition, no information on animals (clinical signs, systemic toxicity) was provided. No histopathology of investigated tissues was performed and therefore no final conclusion on cytotoxicity in the respective tissues is possible, which may have an impact on and explain the outcome of the comet assay.

No induction of double strand breaks was observed in the experiments from Suárez-Larios *et al.* (2017, CA 5.4/009).

Roustan *et al.* (2014) reported that AMPA did result in increased ROS level in CHO-K1 cells. Nevertheless, due the reporting of the results (only one of four tested concentrations of AMPA reported; no standard deviation provided) and the lack of statistical evaluation a final conclusion on the ROS induction by AMPA is not possible. With regards to micronucleus induction a statistical significant increase of cells with micronuclei was observed after treatment with AMPA at concentrations as low as 0.01 ~~m~~µg/mL (equivalent to a high physiological dose of about 60 µM). However, when tested in combination with other pesticides including glyphosate no induction of cells with micronuclei was observed at concentrations from 5 to 100 µg/mL. Taking into account the available in vivo micronuclei tests yielding negative results, a clastogenic potential of AMPA is unlikely.

Nota bene: In autumn of 2019 NGOs and media published accusations against the German based contract research organization "[redacted]" on animal welfare and GLP. In the frame of this glyphosate renewal dossier GRG is submitting 24 studies performed during the years 1995 – 2010 at [redacted]. All these studies were conducted during the validity periods of GLP certificates routinely renewed and re-confirming the GLP-standard every three years. Studies performed at this laboratory are clearly indicated in the overview table (Table 5.8.1-1) as well as in the respective study header. Due to the large number of corroborative studies available within the Glyphosate Renewal Group,

the overall endpoint conclusion of glyphosate is not reliant on the results of the studies performed at [redacted].

1. Information on the study

Data point:	CA 5.8.1/001
Report author	[redacted]
Report year	1973
Report title	Final Report on CP 67573 RESIDUE AND METABOLISM Part 11: The Metabolism of Aminomethylphosphonic Acid-^{14}C (CP 50435-^{14}C) in the Laboratory Rat

Report No	303
Document No	NA
Guidelines followed in study	None stated
Deviations from current test guideline	Yes, reporting deficiencies (no batch or purity of test material, only one dose, only 5 days)
Previous evaluation	Not accepted in RAR (2015)
GLP/Officially recognised testing facilities	No, study conducted prior to GLP
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary

Executive summary

These studies were initiated to investigate the metabolic fate of aminomethylphosphonic acid-^{14}C ([^{14}C]-AMPA), in the rat following a single oral dose to rats.

Male Wistar rats received a single dose of approximately 6.7 mg [^{14}C]-AMPA/kg bw by oral gavage and were sacrificed 120 hours (5 days) after dosing. During this period, urine, faeces and expired gases were collected at 12 or 24 hour intervals and assayed for radioactivity. At sacrifice, blood and selected tissues were examined for radioactive residues.

74 % of the applied dose was detected in faeces and 20 % in urine with less than 0.1 % expired as $^{14}CO_2$ 120 h after application. Therefore, the recovery of administered radioactivity in excreta exceeded 90 %. Approximately 0.06 % of the original dose was recovered from the carcass at 120 hours post-administration, but liver, kidney and muscle exhibited residues of only 6, 6 and 3 ppb, respectively.

Chromatographic and spectral data have demonstrated that orally administered [C^{14}]-AMPA is excreted unchanged in the urine.

I. MATERIALS AND METHODS

A. MATERIALS

1. Radiolabelled test material: Aminomethylphosphonic acid-^{14}C

Identification:	Aminomethylphosphonic acid-^{14}C (CP 50435-^{14}C) (AMPA-^{14}C)
Position of radiolabel:	Not stated
Lot/Batch #:	Not reported
Purity:	Not reported
Specific activity:	8.9 mCi/mmol
Stability of test compound:	Not reported

2. Test animals:

Species:	Rat
Strain:	Wistar

Source:	[redacted]
Age:	Not stated, but about 6 to 8 weeks considering the body weight
Sex:	Male
Weight at dosing:	Approximately 150 g
Acclimation period:	Not reported
Diet/Food:	*ad libitum,* fasted 4 hours prior to dose
Water:	*ad libitum*
Housing:	Individually in Roth metabolism cages
Environmental conditions:	Temperature: not reported Humidity: not reported Air changes: not reported

B. STUDY DESIGN

Animal assignment and treatment

Male rats were fasted for four hours, before application of an aqueous solution containing approximately 1 mg of [^{14}C]-AMPA (corresponding to a dose of 6.7 mg/kg bw) by gavage. Urine, faeces and the 1N NaOH used to trap the expired gases were collected after 12, 24, 48, 72, 96 and 120 hours. At termination a heparinised blood sample was taken by cardiac puncture under light ether anaesthesia. The animal was sacrificed by continued ether anaesthesia and the following tissues removed: liver, kidney, spleen, heart, brain, testes, fat, muscle and the gastrointestinal tract (GIT) from the oesophagus to the rectum including the caecum.

Measurement of radioactivity in excreta and expired gases

One ml of the NaOH trapping solution was diluted with 2 mL water, and 15 mL phosphor solution (Insta-Gel-Packard Instrument Co., Downers Grove, Ill.) added and the sample analysed for $^{14}CO_2$ by liquid scintillation counting.

Urine was analysed for ^{14}C-activity by diluting 0.1 mL and 0.2 mL aliquots with 4 mL 0.1M NH_4HCO_3. 15 mL phosphor solution was added and the mixture shaken vigorously and chilled to form a gel. The samples were then analysed by liquid scintillation counting.

Faeces was homogenised in 30 % aqueous isopropyl alcohol. The faeces homogenate was lyophilized and 100 mg aliquots submitted for combustion. The trapped ^{14}C-activity was analysed by liquid scintillation counting.

Measurement of radioactivity in tissues

The collected tissue samples were weighed, frozen and lyophilized. The lyophilized samples were weighed, aliquoted and submitted for combustion and subsequent liquid scintillation counting.

Isolation of AMPA-^{14}C from rat urine

A cation-exchange column was prepared by pouring aqueous slurry of AG-50W-X8 (H^+ form; 200/400 m). The resin bed was washed with distilled water until the eluate was colourless. A 12 or 24 hour urine sample which had been diluted to 25-35 mL with distilled water was loaded onto this cation exchanger. The column was then eluted with 1500 mL distilled water and 20 mL fractions were collected. The eluent fractions

which contained radioactivity were pooled and loaded onto an anion-exchanger of AG-1-x8 (HCO_3^- form, 200/400 m). The resin was prepared from the Cl^- form by passing 1M NH_4 hCO$_3$ (2L 1M NH_4 hCO3/1b resin) through the resin. The resin was then washed with water until the eluate was neutral. An amount of resin equivalent to 20 g dry weight was slurried with water and poured into a glass column forming a resin bed. The sample was then applied in a volume of 200 mL. The column was eluted with 200 mL distilled water, followed by 300 mL 0.2N NH_4HCO_3. Fractions of 5 or 10 mL were collected.

The eluent fractions from the anion exchanger which contained radioactivity were pooled and reduced to 1 – 1.5 mL and loaded onto a Bio-Gel P-2 column for gel-filtration chromatography. The gel was prepared by suspension in 0.5N acetic acid, deaerator with a water aspirator and pouring the slurry into a column to form a bed of 1 x 108 cm. After the sample was charged onto the column, the sample flask was rinsed with 1 - 2 mL distilled water which was added to the column. The column was then eluted with 200 mL 0.5N acetic acid and 1 - 2 mL fractions collected.

Authentic standards of radiolabelled AMPA added to urine from untreated rats were eluted quantitatively from the cation exchange resin. Those fractions containing ^{14}C-activity were then pooled, reduced in volume and chromatographed on an anion exchanger and subsequently on a gel filtration column. Typically, overall recoveries of ^{14}C-activity from [^{14}C]-AMPA enriched rat urine were approximately 70 % of initial ^{14}C-activity. Urine from rats orally administered [^{14}C]-AMPA which was chromatographed in the same way resulted in approximately 60 % recovery of the initial ^{14}C-activity present in the crude urine.

Thin layer chromatography (TLC)

The Bio-Gel fractions which contained radioactivity were pooled reduced to small volume and an aliquot applied to a 20 x 20 cm thin-layer chromatography (TLC) plate with a 250 µ layer of microcrystalline cellulose. The plates were developed first in a phenol-water system of the following composition:

90 % Phenol (Fisher Certified)	84 mL	
Distilled Water		16 mL
Glacial Acetic Acid		1 mL
EDTA		37.2 mg

After the plates were air-dried, they were rotated 90° and developed in a modified semi-stench solvent system of the following composition:

EDTA		1.2 g
17N NH_4OH		100 mL
Distilled Water		475 mL
l-Propanol		350 mL
2-Propanol		75 mL
l-Butanol		75 mL
Iso-Butyric Acid	2500 mL	

Colorimetric visualization of the TLC plates was accomplished by spraying with or with a modified Hanes reagent. ^{14}C-activity on the TLC plates was detected by means of the Beta Camera, Model 6000. A permanent copy of the Beta Camera CRT image was reproduced using a Polaroid Pack Camera.

Nuclear Magnetic Resonance (^{1}H-NMR) of the isolated fractions

The samples were lyophilized and exchanged twice with 99.8 % deuterium oxide (D_2O). The sample was then dissolved in 0.1 mL 100 % D_2O. Immediately before running the spectra, the samples were dissolved in 10 µl 100 % D_2O and the solution filtered through a Flath-Ludin syringe filter directly into a capillary tube. An additional 5 µL D_2O was used to rinse the vial and was also filtered directly into the capillary tube. The capillary was inserted into a teflon chuck which was then placed in a 7 inch NMR tube (Wilmad, No.

529-PP).

High resolution proton spectra (60 mHz) were run on a Varian T-60 and/or a JEOL JNM C-60-HL spectrometer. The latter was equipped with a JNM-AS-1 resolution stabilizer, JRA-1 spectrum accumulator, Monsanto 100-A frequency counter, an external Hewlett Packard Model 200 CD wide range audio oscillator, a Hewlett Packard Model 5245L electronic counter, a hetero spin decoupler (JNM-5D-HC) and an RF oscillator adapter (JNM-OA-1). All ^{1}H-NMR spectra were calibrated using HOD as the internal reference and were decoupled using the hetero spin decoupler (JNM-5D-HC) and an RF oscillator adapter (JNM-OA-1).

Gas-Liquid Chromatography (GLC) of the isolated fractions

Following NMR analysis the samples were derivatized using trifluoroacetic acid, trifluoroacetic anhydride, diazobutane and acetic acid in benzene and examined by GLC on a Perkin-Elmer Model 900 which is a dual column instrument equipped with thermal conductivity (TC), flame ionization (FID) and phosphorus specific (FPD) detectors. The samples were analysed on a glass column packed with 1 – 5 % OV-17 on Chromosorb W-HP (80/100 m) programed from l20 – 240 °C at 10 °C/min.

Mass Spectrometry of the isolated fractions

The final analysis of the purified fractions was performed by coupled gas chromatography and mass spectrometry. A PE-900 GLC was coupled through a Rieman separator to a Perkin-Elmer Model 270 mass spectrometer (MS) operating at 70 ev in the GLC mode. A Honeywell 2106 Visicorder was employed to focus the instrument and record the mass spectra. The PE-270 MS was interfaced through a Hall probe to a Varian SS-100MS data system.

II. RESULTS AND DISCUSSION

A. DISTRIBUTION OF RADIOACTIVITY FOLLOWING ORAL ADMINISTRATION OF [^{14}C]-AMPA

The major route of excretion of orally administered [^{14}C]-AMPA is via the faeces. More than 50 % of the administered dose was excreted in the faeces within 24 hours and a total of 74 % within 120 hours.

13 % of the dose was recovered from the urine within 12 hours after administration, 4.5 % was detected urine collected 12 - 24 hours after application and less than 3 % was detected in urine collected from 24 - 120 hours. Thus, most of the absorbed material was excreted within 24 hours.

Very little of the absorbed material was catabolised. Less than 0.1 % of the administered ^{14}C-activity was recovered in expired air.

Table 5.8.1-2: Distribution of ^{14}C-activity in male rats orally administered [^{14}C]-AMPA

Time (Hour)	Percent dose recovered[1]					
	Urine	Faeces	CO_2	Washes[2]	Tissues	Cumulative
12	13.04	5.86	0.06			18.95
24	4.50	47.24	0.01			70.70
48	1.52	19.30	0.00			91.52
72	0.66	0.91	0.00			93.09
96	0.23	0.12	0.00			93.44
120	0.05	0.06	0.00			93.55
Total	**20.00**	**73.49**	**0.06**	**0.13**	**0.06**	**93.74**

[1]Dose was 6.7 mg/kg body weight
[2]Consists of 0.1M NH_4HCO_3 washes of cage and urine-faeces separator

Approximately 0.06 % of the administered ^{14}C-activity could be accounted for in the carcass 120 hours following a single oral dose. Of that ^{14}C-activity the muscle, due to its large relative mass, i.e., 38 % of the total live weight, accounted for approximately one-third of the ^{14}C-activity. However, the concentration calculated on the basis of AMPA-^{14}C equivalents was only 3 ppb in fresh tissue. In addition, the liver and kidney were only 6 ppb.

Table 5.8.1-3: Radioactivity in tissues 120 h after single oral dose of 6.7 mg [^{14}C]-AMPA/kg bw (in µg/g fresh tissue)

Tissue	% Dose	[^{14}C]-AMPA equivalents (µg/g Fresh tissue)
Liver	0.01	0.006
Kidney	<0.01	0.006
Muscle	0.02	0.003
Fat	0.01	0.004
Gut	0.02	0.008
Spleen	<0.01	0.004
Heart	<0.01	0.004
Brain	<0.01	0.001
Testes	<0.01	0.003
Blood	<0.01	0.003

B. CHARACTERIZATION OF THE EXCRETED RADIOACTIVITY.

The purification and spectral methods employed were defined on a urine sample from an untreated control rat. The urine was spiked with approximately 500 µg [^{14}C]-AMPA. The TLC screening procedure is capable of separating the following compounds: glyphosate, AMPA, N-methylaminomethylphosphonic acid, glycine, sarcosine, methylphosphonic acid and hydroxymethylphosphonic acid.

Recovery of ^{14}C-activity from [^{14}C]-AMPA enriched rat urine was approximately 70 % of initial ^{14}C-activity. Urine from rats orally administered [^{14}C]-AMPA which was chromatographed in the same way resulted in approximately 60 % recovery of the initial ^{14}C-activity present in the crude urine.

The purified urine samples were analysed by ^{1}H-NMR after being exchanged with D_2O. The sample isolated from the urine of rats administered [^{14}C]-AMPA exhibited the characteristic doublet due to the methylene protons, although it was not as well defined as in the sample enriched with [^{14}C]-AMPA. However, the chemical shifts for the methylene protons are consistent with those determined for authentic standards, and the ^{31}P-decoupled spectrum shows a clear enhancement in the intensity of the response.

The samples which had been analysed by ^{1}H-NMR were exchanged with water and derivatised for GLC/MS analysis. The mass spectrum of the Di-n-butyl-*N*-trifluoromethyl derivative of the sample isolated from urine enriched with [^{14}C]-AMPA yielded the same basic fragmentation pattern as the spectrum of the standard AMPA-Di-n-butyl-TFA.

Beside the peak of AMPA-Di-n-butyl-TFA additional peaks were observed in urine (P+2) spiked with [^{14}C]-AMPA contributing significantly to fragments containing the ^{14}C-enriched methylene group. In the sample in which [^{14}C]-AMPA was added to and isolated from an untreated urine sample, there are four fragments showing a significant P+2 peak.

The mass spectra of the sample isolated from rat urine have the same characteristic fragmentation pattern as the standard AMPA. The relative intensities of some of the lower mass fragments vary from the standard, but these are not as significant in identification as the higher mass fragments which agree well with the standard.

III. CONCLUSIONS

Orally administered AMPA is only moderately absorbed from the gut of the rat after single application of 6.7 mg/kg bw. Consequently, the faeces represent the major route of excretion of ingested AMPA. Approximately 20 % of the material is absorbed and most of that amount is rapidly excreted unchanged in the urine. Of the material absorbed, very small amounts are catabolized as evidenced by the facts that less than 0.1 % of the dose is expired in air and tissue residues are less than 10 ppb.

The absorption of [^{14}C]-AMPA from the gut appears to be slightly more rapid than glyphosate since the log unexcreted dose (i.e., body load) versus time plot of AMPA shows only a small distributive phase. However, the biological half-life of [^{14}C]-AMPA of 10-11 hours is of approximately the same magnitude as that of glyphosate which was 8-9 hours. But unlike glyphosate, [^{14}C]-AMPA did not show a redistribution phase at 48-96 hours which plateaued the excretion curve followed by resumption of first-order elimination. Rather at approximately 72 hours the elimination curve simply plateaued as if approaching an asymptote.

3. Assessment and conclusion

<u>Assessment and conclusion by applicant</u>:

The excreta from male rats orally administered [^{14}C]-AMPA were collected at various intervals through 120 hours post-administration and analysed for ^{14}C-activity.

It was found that a total of approximately 74 % of the dose appeared in the faeces and ca 20 % in the urine with less than 0.1 % expired in air. These figures suggest only limited absorption from the gastrointestinal tract. Elimination is rapid and nearly complete. More than 50 % was excreted in the faeces during the first 24 hours following dosing. About 13 % of the administered dose was found in the urine within the first 12 hours already. Approximately 0.06 % of the total dose only was recovered from the carcass at 120 hours post dose. Liver, kidney and muscle exhibited residues of 6, 6 and 3 ppb, respectively. Chromatographic and spectral data demonstrated that the orally administered AMPA was excreted unchanged in the urine. There was no indication of further metabolism.

The report does not contain any information on the limits of detection or limits of quantitation.

The reporting in this study is very brief and can be considered to be poor and therefore, it is not acceptable based on current regulatory standards.

<u>Assessment and conclusion by RMS</u>:

Acute oral toxicity

1. Information on the study

Data point	CA 5.8.1/002
Report author	[redacted]

Report year	1996
Report title	AMPA: Acute Oral Toxicity Study in Mice
Report No	[redacted] 96-0075
Document No	NA
Guidelines followed in study	OECD 401 (1987); US EPA FIFRA Guidelines Subdivision F (1994); Japan MAFF Guidelines 59 NohSan No. 4200 (1985)
Deviations from current test guideline	The study was conducted according to OECD 401 however the deviation was identified according to OECD 420 adopted in 2001 to replace OECD 401. Clinical signs of toxicity were measured 1 hour after initial dosing, not 30 minutes after initial dosing as recommended by OECD 420.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive Summary

AMPA was evaluated for its acute oral toxicity potential in male and female mice when administered as a gavage dose at a level of 5000 mg/kg bw. No mortality occurred during the 14-day observation period and no clinical signs were observed at necropsy following the observation period. There was no effect on body weight gain. The gross necropsy conducted at termination of the study demonstrated no observable abnormalities. The acute oral LD_{50} was determined to be;

LD_{50}, oral, male and female mouse > 5000 mg/kg bw

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: AMPA

Identification: AMPA

Description: White powder

Lot/Batch #: 20080801

Purity: 99.33 %

Stability of test compound: Stable for 1 year at room temperature

2. Vehicle and/ or positive control: 1 % carboxymethylcellulose

3. Test animals:

Species: ICR mice

Strain / Stock: Crj:CD-1

Source: [redacted]

Age:	5 weeks
Sex:	Male and female
Weight at dosing:	30.5 – 34.6 g for males; 22.9 – 24.8 g for females
Acclimation period:	7 days
Diet/Food:	Certified pellet diet MF (Oriental Yeast Co., Ltd., Azusawa, Itabashi-ku, Tokyo), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Groups of 5 animals/sex/cage were housed in aluminium cages with wire-mesh floors
Environmental conditions:	Temperature: 22 ± 3°C Rel. humidity: 55 ± 15 % 12-hour light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 17 September 1996 to 8 October 1996

Animal assignment and treatment

Based on the results of a preliminary dose-range finding study, 5000 mg/kg bw/day was selected as the dose level for this study.

Table 5.8.1-4: AMPA: Acute Oral Toxicity Study in Mice ([redacted], 1996): animal distribution

	Dose (mg/kg bw/day)	Number of Animals Per Group	
		Males	Females
Test Group	5000	5	5

Animals were fasted for about 3 hours before and 3 hours after administration. The dosing volume was 20 mL/kg bw. Observations for clinical signs of toxicity were made 1, 3, and 6 hours after administration and then once daily thereafter until termination of the observation period. Individual body weights were recorded just prior to dosing, as well as 7 and 14 days after administration. On Day 14 after dosing, all animals were sacrificed under ether anaesthesia and subjected to necropsy.

II. RESULTS AND DISCUSSION

A. MORTALITY
There were no mortalities during the study.

B. CLINICAL OBSERVATIONS
No clinical signs were observed during the study.

C. BODY WEIGHT
Body weight gain was unaffected by the administration of the test substance.

D. NECROPSY
The gross necropsy conducted at termination of the study demonstrated no observable abnormalities.

III. CONCLUSIONS

The oral LD_{50} of the test material (AMPA) in mice was estimated to be greater than 5000 mg/kg bw.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In a GLP study conducted in accordance with OECD 401 guidelines (1987), the acute oral LD_{50} for AMPA was determined to be greater than 5000 mg/kg bw in male and female mice. The study is considered reliable because of its adherence to current study guidelines.

Assessment and conclusion by RMS:

2. Full summary

Executive Summary

The acute oral toxicity of glyphosate's metabolite AMPA was investigated in male and female rats (5 animals/sex/group) of the Sprague-Dawley strain. The test substance, suspended in 0.5 % carboxymethylcellulose, was administered by oral gavage to each animal at a dosage of 5000 mg/kg bw and a constant dose volume of 10 mL/kg bw. Mortality, body weight and clinical signs were recorded during the subsequent 14 days. All animals were subjected to a gross necropsy at the end of the study.

Clinical signs noticed were piloerection, diarrhea, subdued behavior, hunched appearance, and soiled anal and perigenital areas. Changes of body weight were in the normal range. No Mortality occurred. No abnormal necropsy findings were noted.

The acute oral LD_{50} was calculated to be;

LD_{50}, oral, female and male rat > 5000 mg/kg bw

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Glyphosate metabolite
Identification:	AMPA
Description:	White powder
Lot/Batch #:	286-JRJ-73-4

Water:	Tap water, *ad libitum*
Housing:	5 animals/sex/cage in Polypropylene cages with mesh floors suspended over absorbent paper lined trays
Environmental conditions:	Temperature: 18 °C - 21 °C Humidity: 39 % (Average) Air changes: 15 – 20 times per hour 12-hour light/dark cycle (light during 07:00 – 19:00)

B. STUDY DESIGN AND METHODS

In life dates:

01/04/1992 to 15/04/1992 (experimental phase)
Finalisation date: 28/01/1993.

Animal assignment and treatment:

Rats were housed by sex (5 males and 5 females) and starved the night prior to dosing.

The test material was suspended in 0.5 % CMC at concentration of 500 mg/mL and administered by a single oral gavage at dose level of 5000 mg/kg bw with an application volume of 10 mL/kg bw. After dosing, the animals were starved for a further 4 hours.

All animals were observed for clinical signs of toxicity at several time points on the day of administration and at least once a day, thereafter for a period of 14 days. Body weights were recorded prior to administration, day seven and prior to sacrifice on day 14.

At study termination all animals were sacrificed by carbon dioxide asphyxiation followed by a gross necropsy examination.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred during the 14-days observation period after administration.

The oral LD_{50} is above 5000 mg/kg bw for male and female rats.

B. CLINICAL OBSERVATIONS

Clinical signs observed, were piloerection, diarrhea, subdued behavior, hunched appearance, and soiled anal and perigenital areas. These observations appeared at 4 hours post dosing the first time. Females recovered after day 1, while piloerection in males lasted until day 4 of the study. All clinical signs are listed in table below.

Table 5.8.1-5: AMPA: Acute oral toxicity (limit) test in rats ([redacted], 1993): Clinical observations

Dose group		5000 mg/kg bw									
Sex		Males						Females			
Time after treatment		1 min - 2 h	4 h	1 d	2 d	3 d	4 – 14 d	1 min – 2 h	4 h	1 d	2 – 14 d
Total animals examined	n	5	5	5	5	5	5	5	5	5	5
Clinical sign	n	0	5	5	3	2	0	0	5	5	0

Diarrhea			5	5					5		
Hunched appearance				1	1					3	
Soiled anal and perigenital areas				3						3	
Subdued behaviour									5		

C. BODY WEIGHT

Weight gain of all animals was within the normal range. Individual body weights are depicted in the table below.

Table 5.8.1-6: AMPA: Acute oral toxicity (limit) test in rats ([redacted], 1993): Body weights

Dose group		5000 mg/kg bw	
Sex		Males	Females
Body weight (g)			
Day 0	Mean	168	148
	± SD	5	12

Day 7	Mean	216	180
	± SD	12	12
Day 14	Mean	256	199
	± SD	18	10
Body weight gain	Mean	88	51
	± SD	18	7

D. NECROPSY

No abnormal necropsy findings were noticed.

III. CONCLUSIONS

The oral LD_{50} of the test material (AMPA) in rats was estimated to be greater than 5000 mg/kg bw.

3. Assessment and conclusion

Assessment and conclusion by applicant:

As no mortality occurred during the study period, the oral LD_{50} of glyphosate metabolite AMPA in rats is greater than 5000 mg/kg bw. No deviations from the current test guideline were identified, therefore the study is considered acceptable.

Water:	Water acidified with hydrochloric acid to pH 2.5, *ad libitum*
Housing:	2-3/sex/cage in macrolone cages Type III (42x26x15 cm) with pinewood sawdust bedding
Environmental conditions:	Temperature: 21 ± 3 °C Humidity: 55 ± 15 % (Average) Air changes: 6 times per hour 12-hour light/dark cycle (light during 06:00 – 18:00)

B. STUDY DESIGN AND METHODS

In life dates:

04/07/1991 to 18/07/1991 (experimental phase).
Finalisation date 14/10/1991.

Animal assignment and treatment

Rats were housed by sex (5 males and 5 females) and fasted 18 hours prior to dosing with the test material. The substance was suspended in 1 % CMC and administered by a single oral gavage at a dose level of 5000 mg/kg bw with an application volume of 20 mL/kg bw. After dosing, the animals were fasted for a further 3 hours. A control group was included in the study. The animals of this group received the vehicle only under the same conditions and dose volume as the test group.

All animals were observed for clinical signs of toxicity at several time points on the day of administration and at least once a day, thereafter for a period of 14 days. Body weights were recorded prior to administration, day seven and prior to sacrifice on day 14.

At study termination all animals were sacrificed by carbon dioxide asphyxiation followed by a gross necropsy examination.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality occurred during the 14-days observation period after administration.

The oral LD_{50} is above 5000 mg/kg bw for male and female rats.

B. CLINICAL OBSERVATIONS

Clinical signs observed in the control group included piloerection and pinched abdomen.
The animals of the test group showed the same signs and diarrhea in addition. The observations in the test group had resolved on day 2 while observations in the test group persisted until day 3 of the study. All clinical signs are listed in the following table.

Table 5.8.1-7: Assessment of acute oral toxicity of (N-methyl-N-phosphonomethyl)glycine to rats ([redacted], 1992): Clinical observations

Dose group (mg/kg bw)		0					5000										
Time after treatment		1 h	3 h	5 h	1 d	2 – 14 d	1 h	3 h	5 h	1 d	2 d	3 d	4 d	5 d	6 d	7 d	8 – 14 d
Total animals examined	n	10	10	10	10	10	10	10	10	10	10	10	10	10	10	10	10
Clinical sign	n	10	10	10	3	0	10	10	10	10	9	0	2	1	0	1	0

Pinched abdomen		1M/2F					10	5M/2F	1M								
Diarrhea											4M						

M = males; F = females

C. BODY WEIGHT

Weight gain of all animals was within the normal range. Individual body weights are depicted in the following table.

Table 5.8.1-8: Assessment of acute oral toxicity of (N-methyl-N-phosphonomethyl)glycine to rats ([redacted], 1991): Body weights

Dose group (mg/kg bw)		0	5000	0	5000
Sex		Males		Females	
Body weight (g)					
Day 0	Mean	143	153	150	153
	± SD	2	2	2	2
Day 7	Mean	200	197	187	186
	± SD	4	10	4	4
Day 14	Mean	251	248	207	206
	± SD	4	9	4	5

D. NECROPSY

No abnormal necropsy findings were noticed.

III. CONCLUSIONS

The oral LD_{50} of the test material (N-methyl-N-phosphonomethyl)glycine in rats was estimated to be greater than 5000 mg/kg bw.

3. Assessment and conclusion

Assessment and conclusion by applicant:

As no mortality occurred during the study period, the oral LD_{50} of the test material was estimated to be greater than 5000 mg/kg bw. A control group was used in this study, deviating from the current test guideline. However, this is not interfering with the obtained results and the study is considered acceptable.

Assessment and conclusion by RMS:

Report year	1988
Report title	Aminomethyl Phosphonic Acid: Acute Oral Toxicity to the Rat
Report No	[redacted]/P/2266
Document No	NA
Guidelines followed in study	No guideline specified in the report
Deviations from current test guideline	None
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised	Yes

testing facilities	
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

Aminomethyl phosphonic acid was evaluated for its acute oral toxicity potential in male and female rats when administered as a gavage dose at a level of 5000 mg/kg bw. No mortality occurred during the 14-day observation period. Slight clinical signs of toxicity were observed following dosing but were resolved by Day 4. All animals exhibited a decrease in body weight due to the pre-dose fast; however, body weights normalized by Day 6. Decreased body weights were again observed on Days 6 and 8 for one male, as well as on Days 8 through 15 for one male and three females. The gross necropsy conducted at termination of the study demonstrated no observable abnormalities. The acute oral LD_{50} was determined to be;

LD_{50}, oral, male and female rat > 5000 mg/kg bw

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Aminomethyl phosphonic acid

Stability of test compound:	Not reported
2. Vehicle and/ or positive control:	0.5 % (w/v) aqueous polysorbate 80
3. Test animals:	
Species:	Wistar-derived albino rats
Strain / Stock:	Alpk:APfSD
Source:	[redacted]
Age:	8 - 9 weeks
Sex:	Male and female
Weight at dosing:	280 - 312 for males; 204 - 214 g for females
Acclimation period:	Maximum of 6 days
Diet/Food:	Porton Combined Diet, Special Diets Services Ltd, *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	A maximum 5 animals/sex/cage were housed in suspended cages with stainless steel mesh floor and back
Environmental conditions:	Temperature: 15 – 24 °C Rel. humidity: 50 ± 10 % Air changes: 20 – 30 air changes per hour 12-hour light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: Not reported

Animal assignment and treatment

Based on the results of a preliminary dose-range finding study, 5000 mg/kg bw/day was selected as the dose level for this study.

Table 5.8.1-9: Aminomethyl Phosphonic Acid: Acute Oral Toxicity to the Rat ([redacted], 1998): animal distribution

	Dose (mg/kg bw/day)	Number of Animals Per Group	
		Males	Females
Test Group	5000	5	5

Animals were fasted overnight for a period of up to 24 hours prior to dosing. One female was accidentally killed on Day 1 and was therefore substituted with another animal that was dosed one day later. The dosing volume was 10 mL/kg bw. Observations for clinical signs of toxicity were made once 30 and 90 minutes after dosing and again between 4 and 6 hours after dosing. Individual body weights were recorded one the day prior to dosing, the day of dosing and on Days 3, 5 or 6, 8, and 15. At the end of the study, all animals were sacrificed via inhalation of halothane BP and examined for gross abnormalities.

II. RESULTS AND DISCUSSION

A. MORTALITY

There were no mortalities during the study.

B. CLINICAL OBSERVATIONS

Slight signs of clinical toxicity were observed in all animals; however, all animals recovered by Day 3 or 4.

Table 5.8.1-10: Aminomethyl Phosphonic Acid: Acute Oral Toxicity to the Rat ([redacted], 1998): clinical signs of toxicity

	From Days 1 through 15	
	Males	Females
Diarrhea	2/5	1/6
Signs of diarrhea	4/5	2/6
Chromodacryorrhea	2/5	2/6
Piloerection	1/5	1/6
Stains around nose	2/5	4/6
Signs of urinary incontinence	1/5	5/6
Ungroomed	5/5	4/6
Reduced splay reflex	0/5	2/6

C. BODY WEIGHT

All animals exhibited decreased body weights due to the pre-dosing fast; however, all weights were

normalized by Day 6. After Day 6, one male lost weight between Days 6 and 8. Three females and one male also lost weight between Days 8 through 15.

Table 5.8.1-11: Aminomethyl Phosphonic Acid: Acute Oral Toxicity to the Rat ([redacted], 1998): body weight (mean ± standard deviation)

	From Days 1 through 15	
	Males	**Females**
Pre-dosing	293.2 ± 12.1	207.7 ± 3.7
Day 1	263.6 ± 12.3	186.8 ± 2.7
Day 3	285.4 ± 9.4	209.6 ± 3.8
Day 5	n/a	217.0 ± 0.0
Day 6	311.0 ± 9.7	223.0 ± 4.0
Day 8	325.0 ± 51.6	248.2 ± 27.4
Day 15	364.0 ± 12.7	245.0 ± 7.1

n/a: not applicable

D. NECROPSY

The gross necropsy conducted at termination of the study demonstrated no observable abnormalities.

III. CONCLUSIONS

The oral LD_{50} of aminomethyl phosphonic acid in rats was estimated to be greater than 5000 mg/kg bw.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In a GLP study conducted in a similar to OECD 420, the acute oral LD_{50} for aminomethyl phosphonic acid was determined to be greater than 5000 mg/kg bw in male and female rats. The study is considered reliable because of its adherence to current study guidelines.

Assessment and conclusion by RMS:

2. Full summary

Executive summary

The acute oral toxicity of glyphosate's metabolite CP 50435 was investigated in male and female rats (5 animals/group). The test substance, suspended in corn oil, was administered by a single oral gavage to each animal at a dosage of 5010 mg/kg bw, 6310 mg/kg bw, 7940 mg/kg bw and 10000 mg/kg bw. Mortality and clinical signs were recorded during the subsequent 7 days. All animals were subjected to a gross necropsy at the end of the study.

Clinical signs noticed were reduced appetite, reduced activity, increasing weakness, slight diarrhoea and collapse. Mortality occurred in 1/5 rats at 6310 mg/kg bw, 2/5 rats at 7940 mg/kg bw and 4/5 rats at 10000 mg/kg bw. No abnormal necropsy findings were noted in animals that survived until the end of the study period.

The acute oral LD_{50} was calculated to be;

LD_{50}, oral, female and male rat 8300 mg/kg bw (CI: 7300 mg/kg bw – 9460 mg/kg bw)

I. MATERIALS AND METHODS

Housing:	Not specified

Environmental conditions: Temperature: Not specified
Humidity: Not specified

B. STUDY DESIGN AND METHODS

In life dates:
Not specified.
Finalisation date 07/03/1973

Animal assignment and treatment

The test substance was suspended in corn oil and administered by a single oral gavage to 5 rats (mixed gender) per dose group at a dose level of 5010 mg/kg bw, 6310 mg/kg bw, 7940 mg/kg bw and 10000 mg/kg bw.

All animals were observed for clinical signs of toxicity for a period of 7 days.

At study termination all animals were sacrificed and subjected to a gross necropsy examination.

II. RESULTS AND DISCUSSION

A. MORTALITY

No mortality was observed in lowest dose group (5010 mg/kg bw). Mortality occurred in 1/5 rats at 6310 mg/kg bw, 2/5 at 7940 mg/kg bw and 4/5 at 10000 mg/kg bw (see table below).
The oral LD_{50} is 8300 mg/kg bw for male and female rats (CI: 7300 mg/kg bw – 9460 mg/kg bw).

Table 5.8.1-12: Toxicological investigation of: CP 50435 – Lot: XHD-16 ([redacted], 1973): Mortality for all dose groups

Dose level (mg/kg bw)	Animal No.		No. of deaths/No. of animals examined (Day of death)	
	Males	Females	Males	Females
5.010	2, 4	1, 3, 5	-	-
6.310	6, 8, 10	7, 9	-	1/2([a])
7.940	12, 14	11, 13, 15	1/2([a])	1/3([a])
10.000	16, 18, 20	17, 19	3/3([a])	1/2([a])

- = No death
[a] Day of death not mentioned in the study report

B. CLINICAL OBSERVATIONS

Clinical signs observed included reduced appetite, reduced activity on days 1 to 3 after treatment. Furthermore, increased weakness, slight diarrhea and collapse were observed.

C. BODY WEIGHT

Body weight was not measured after treatment.

D. NECROPSY

Animals that died during the study showed slight liver discoloration and acute gastrointestinal

inflammation. Animals that were sacrificed at the end of the study period did reveal abnormal necropsy findings.

III. CONCLUSIONS

The oral LD_{50} of the test material in rats was estimated to be 8300 mg/kg bw with a lower and upper limit of 7300 to 9460 mg/kg.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Based on mortality data, the LD_{50} was estimated to be 8300 mg/kg bw. However due to the very brief reporting of the experimental design and results, the study was considered as supplementary.

Assessment and conclusion by RMS:

Acute dermal toxicity

#: Following the feedback from the Assessment Group Glyphosate in March 2020, the Notifier is aware of concerns regarding work conducted at this specific contract laboratory ([redacted]). For the sake of completeness, this study is included in the dossier submission since it was part of the data package of previous EU evaluation processes.

2. Full summary

Executive Summary

Aminomethyl phosphonic acid (AMPA) was evaluated for its acute dermal toxicity potential in male and female rats when administered at a dose level of 2000 mg/kg bw. No mortality occurred during the observation period and no clinical signs were observed at necropsy following the observation period. With regard to skin reactions, no erythema or oedema were observed during the study. There was no effect on

body weight gain. The gross necropsy conducted at termination of the study demonstrated no observable abnormalities. The acute dermal LD_{50} was determined to be;

LD_{50}, dermal, male and female rats > 2000 mg/kg bw

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Aminomethyl phosphonic acid (AMPA)
Identification:	AMPA
Description:	White powder
Lot/Batch #:	FA005563
Purity:	98.0 %
Stability of test compound:	Stable until December 21st, 2004
2. Vehicle and/ or positive control:	0.5 % aqueous hydroxypropylmethyl cellulose gel
3. Test animals:	
Species:	Rat
Strain / Stock:	CD® / Crl: CD®
Source:	[redacted]
Age:	20 – 22 days
Sex:	Male and female
Weight at dosing:	214 - 238 g for males; 213 - 223 g for females
Acclimation period:	At least 5 days
Diet/Food:	ssniff® R/M-H V1530 (sniff Spezialdiäten GmbH, D59494 Soet); food was discontinued approximately 16 hours before administration
Water:	Tap water, *ad libitum*
Housing:	Individually housed in Makrolon cages
Environmental conditions:	Temperature: 22 ± 3°C Rel. humidity: 55 ± 15 % 12-hour light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 21 October 2002 to 1 November 2002

Animal assignment and treatment

The test substance was suspended to the appropriate concentration (i.e., 2000 mg/kg bw) in 0.5 % aqueous hydroxypropylmethyl cellulose gel was use applied once for 24 hours on shaved intact dorsal skin of rats.

Table 5.8.1-13: Acute Toxicity Study of AMPA (Aminomethyl Phosphonic Acid) in CD Rats by Dermal Administration – Limit Test ([redacted], 2002): animal distribution

	Dose (mg/kg bw/day)	Number of Animals Per Group	
		Males	Females
Test Group	2000	5	5

The test material was applied to the skin using gauze. The gauze was covered with an occlusive dressing. The exposure time was 24 hours. At the end of the exposure period, possible residual substance was removed. Observations for mortality were made daily. Observations for clinical signs of toxicity were made before and immediately after application. Additional observations were mad 5, 15, 30, and 60 minutes after application, as well as 3, 6, and 24 hours after application. Surviving animals were observed for a total of 14 days. During the two-week follow up period, changes in skin and fur, eyes and mucous membranes, and the respiratory, circulatory, autonomic and central nervous system and somatomotorical activity and behaviour pattern were observed at least once a day until all symptom subsided, thereafter each working day. Attention was given to possible tremor, convulsions, salivation, diarrhoea, lethargy, sleep and coma. Skin was observed for signs of erythema and oedema. Individual body weights were recorded prior to dosing and in weekly intervals thereafter. At the end of the study, all surviving animals were sacrificed, dissected, and inspected macroscopically. Gross pathological changes were recorded.

II. RESULTS AND DISCUSSION

A. MORTALITY

There were no mortalities during the study.

B. CLINICAL OBSERVATIONS

No clinical signs were observed during the study. No influence on animal behaviour were noted. No skin reactions were observed.

C. BODY WEIGHT

Body weight gain was unaffected by the administration of the test substance.

D. NECROPSY

The gross necropsy conducted at termination of the study demonstrated no observable abnormalities.

III. CONCLUSIONS

The dermal LD_{50} of the test material (AMPA) in rats was estimated to be greater than 2000 mg/kg bw.

2. Assessment and conclusion

Assessment and conclusion by applicant:

In a GLP study conducted in accordance with OECD 402 guidelines (1987), the acute dermal LD_{50} for AMPA was determined to be greater than 2000 mg/kg bw in male and female rats. The study is considered reliable because of its adherence to current study guidelines.

Report No	Y-73-19 (Bayer)
Document No	NA
Guidelines followed in study	None followed
Deviations from current test guideline (OECD 404, 2002)	Exposure period was 24 hours not the recommended 4 hours; experimental procedures are only briefly described
Previous evaluation	Not accepted in RAR (2015)
GLP/Officially recognised testing facilities	No, conducted prior to GLP
Acceptability/Reliability	Supportive
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary

Aminomethyl phosphonic acid (AMPA) was tested for its dermal irritating potential. In an *in vivo* study, the 0.5 grams of the test material was applied as a finely ground powder moistened with water to the intact skin of male and female rabbits. The exposure period was 24 hours. The average maximum score was 0.0

out of a possible 8 during the seven-day observation period. Thus, indicating no skin irritating potential.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Aminomethyl phosphonic acid (AMPA)	
Identification:	Not reported	
Description:	Not reported	
Lot/Batch #:	XHD - 16

	Light/dark cycle not reported	

B. STUDY DESIGN AND METHODS

In life dates: Not reported

Animal assignment and treatment:
Animal assignment was not reported in the study report.

The test material (0.5 grams) was applied to intact rabbit skin as a finely ground powder moistened with water. The exposure period was 24 hours.

II. RESULTS AND DISCUSSION

A. MORTALITY
Mortality was not reported.

B. CLINICAL OBSERVATIONS
Clinical signs of toxicity were not reported.

C. BODY WEIGHT
Body weights were not reported.

D. NECROPSY
A necropsy performance was not reported.

E. SKIN REACTIONS
No skin reactions were observed after 24 hours of exposure during the 7-day observation period.

III. CONCLUSIONS

Based on the EU classification criteria, AMPA is not to be classified for skin irritation.

2. Assessment and conclusion

Assessment and conclusion by applicant:

The study is considered supplementary information only as just basic information is given and no individual skin scores are provided. The treatment period was 24 hours instead of 4 hours according to the most recent guideline. Therefore, the result can be considered as worst case. Based on the results of the study, no skin reactions were observed after 24 hours of exposure during the 7-day observation period. Therefore, the test material is not considered to be irritating to the skin.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.8.1/010

Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary
Executive summary

In an eye irritation study, three albino rabbits were treated with glyphosate's metabolite. Therefore, the test substance was instilled into the conjunctival sac of all animals.

Following treatment, eye irritation examined at 1, 24, 48, 72, 120, and 168 hours.

Application of the test substance into the rabbit eye resulted in effects on the conjunctivae (slight to moderate erythema), which all resolved within 120 hours. The individual mean irritation scores could not be calculated as no individual irritation scores were given in the study report.

Body weight at dosing:	Not specified
Acclimation period:	Not specified
Diet/Food:	Not specified
Water:	Not specified
Housing:	Not specified
Environmental conditions:	Not specified

B. STUDY DESIGN AND METHODS

In life dates: Not specified
Finalisation date: 07/03/1973

Animal assignment and treatment

An amount of 100 mg of the test substance was placed into the conjunctival sac of one eye of each animal.

At 1, 24, 48, 72, 120, and 168 hours all eyes were examined for signs of irritation.

II. RESULTS AND DISCUSSION

A. MORTALITY
No mortality occurred.

B. CLINICAL OBSERVATIONS
No clinical signs of systemic toxicity were observed during the study.

C. EYE OBSERVATIONS

Signs of oedema, erythema and discharge were seen in all animals. However, all observations had resolved until 120 hours after treatment (see below).

Table 5.8.1-15: Eye irritation in rabbits after application of 'CP 50435' – Lot: XHD-16 ([redacted] 1973): Eye irritation observations

Animal number		10 min	1 h	24 h	48 h	72 h	120 h	168 h
Cornea	1-3	-	-	-	-	-	-	-
Iris	1-3	-	-	-	-	-	-	-
Conjunctiva Redness	1-3	Slight erythema	Slight erythema	Slight to moderate erythema	Slight to moderate erythema	Slight erythema in one instance	-	-
Conjunctiva Chemosis	1-3	Very slight oedema	Very slight oedema	No oedema	No oedema	No oedema	-	-
Conjunctiva Discharge	1-3	Copius discharge	Copius discharge	Moderate discharge containing whitish exudate	No discharge	No discharge	-	-

III. CONCLUSIONS

Effects on the conjunctiva were observed in all animals. These effects had resolved until 120 hours in all animals. The compound was classified as a slight eye irritant in male and female rabbits.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The classification criteria laid down in the CLP regulation (EC No. 1272/2008) could not be applied to classify the test substance, based on the given study report as there were no individual values given. However, it can be concluded that the test substance is not corrosive as all observations on the eye were reversible within 120 hours after test item application. Detailed reporting of individual animal data is missing, therefore the study is considered as supplementary.

Assessment and conclusion by RMS:

Skin sensitisation

#: Following the feedback from the Assessment Group Glyphosate in March 2020, the Notifier is aware of concerns regarding work conducted at this specific contract laboratory ([redacted]). For the sake of completeness, this study is included in the dossier submission since it was part of the data package of previous EU evaluation processes.

2. Full summary

Aminomethyl phosphonic acid (AMPA) was tested for its sensitising effect on the skin of the guinea pig in the Maximisation Test. The test-substance concentrations for the main test were selected based on the results of the pre-test. The intradermal induction was performed with a 5 % dilution of the test item in a*qua ad iniectabilia*. The epidermal induction was conducted under occlusion with the test item at 50 % one week after the intradermal induction. Two weeks after induction the animals were challenged by epidermal application of the test item at 50 % under occlusive dressing.

The study was performed using one control group consisting of 5 animals, and one test group consisting of 10 animals. None of the animals exhibited a positive skin reaction after the challenge treatment.

II. MATERIALS AND METHODS

Housing:	Housed in pairs in Makrolon cages
Environmental conditions:	Temperature: 22 ± 3°C Humidity: 55 ± 15 % Air changes: not reported 12 hours light/dark cycle

B: Study design and methods

In life dates: 21 October 2002 to 26 November 2002

Animal assignment and treatment

AMPA was tested for its sensitising effect on the skin of the guinea pig using the Maximisation test according to Magnusson and Kligman. Male Dunkin Hartley guinea pigs with body weights ranging from 252 to 307 g were used. The test substance concentrations for the main study were selected based on the results of the pre-testing. The main study was performed in 10 test animals.

Table 5.8.1-16: Examination of AMPA (Aminomethyl Phosphonic Acid) in the Skin Sensitation Test in Guinea Pigs According to Magnusson and Kligman (Maximisation Test) ([redacted], 2002): animal distribution

	Number of Animals Per Group
Pretest	
Intradermal Pretest	2
Epidermal Pretest	6
Main Study	
Negative Control Group	5
Test Group	10
Positive Control Group	20

The induction phase consisted of 3 injections to the intra-scapular region beginning at the cranial and ending at the caudal limits. Two of the injections consisted of 0.1 mL Freund's Complete Adjuvant (FCA) (diluted 1:1 with 0.9 % sodium chloride; 0.1 mL of the test material suspended in *aqua ad iniectabilia*; and 0.1 mL of a mixture of the test material and FCA (1:1). The third injection consisted of a final concentration of the test substance that was equal to that in the second injection. Six days after the injection phase, the application area was shaved and exposed skin was coated with 0.5 mL sodium lauryl sulfate 10 % in Vaseline in order to induce local irritation. On Day 7, an epidermal application was made and the test material was topically applied at a concentration of 50 % to the same shoulder area and covered with an occlusive dressing, which was left in place for 48 hours.

Two weeks after the topical indication, test and control animals were challenged with an occlusive patch

containing the test material at a concentration of 50 %.

For control animals, topical applications used the same procedures as those noted for test animals except that the vehicle (i.e., *aqua ad iniectabilia*) alone was applied. During the challenge phase, the left flank of vehicle control animals was treated with the test material and the right flank was treated with vehicle. Positive control animals were treated with 2 % (w/v) benzocaine solution intracutaneously during the intradermal stage of induction. A 5 % (w/v) benzocaine solution was topically applied during the epidermal stage of induction and during the challenge.

Skin reactions were evaluated at 25 and 28 hours during the intradermal stage of induction and again at 49 and 72 hours during the epidermal stage of induction. Mortality and clinical signs of toxicity were observed daily during the observation period. Body weights were measured at the start of the study and at study termination. Body weights were statistically analysed suing the Student's t-test ($p \leq 0.01$).

Any animal showing erythema at the site of challenge was considered to have shown a positive response.

II. RESULTS

A. MORTALITY

One control animal died during the study.

B. CLINICAL OBSERVATIONS

No clinical signs, other than skin reactions induced by treatment, were noted.

C. BODY WEIGHT

Body weights were considered acceptable.

D. NECROPSY

A necropsy was not performed.

E. SKIN REACTIONS

No skin reactions were observed 24 or 48 h after the challenge treatment with AMPA in the control or test group.

Table 5.8.1-17: Examination of AMPA (Aminomethyl Phosphonic Acid) in the Skin Sensitation Test in Guinea Pigs According to Magnusson and Kligman (Maximisation Test) ([redacted], 2002): number of animals with positive signs following challenge

	Challenge at 25 %	
	24 hours	48 hours
Test group	0/10	0/10
Negative control group	0/5	0/5
Positive control group	20/20	20/20

III. STUDY CONCLUSION

Based on the results of the study, AMPA is not considered a skin sensitiser.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In a study conducted in accordance with OECD 406 guidelines, AMPA is not considered a skin sensitiser based on the results of a guinea pig maximisation test. The study is considered reliable because of its adherence to current study guidelines.

Assessment and conclusion by RMS:

1. Information on the study

2. Full summary

Executive summary

Aminomethyl phosphonic acid (AMPA) was tested for its sensitizing effect on the skin of the guinea pig in the Maximisation Test. The test-substance concentrations for the main test were selected based on the results of the pre-test. The intradermal induction was performed with a 10 % concentration of the test item in 0.5 % carboxymethylcellulose (CMC). The epidermal induction was conducted under occlusion with the test item at 25 % in 0.5 % CMC one week after the intradermal induction. Two weeks after induction the animals were challenged by epidermal application of the test item at 25 % in 0.5 % CMC.

The study was performed using one control group consisting of 20 animals, and one test group consisting of 20 animals. The sensitivity of the strain used was assessed at 6 monthly intervals using a known skin sensitizer e.g. 2,4-dinitro-chlorobenzene. None of the animals in the control and test group exhibited a positive skin reaction after the challenge treatment. Animals treated with the positive control exhibited a skin sensitizing reaction in all animals. Therefore, there is no evidence from the test results that AMPA is a skin sensitizer in guinea pigs.

B. STUDY DESIGN AND METHODS

In life dates: 1 April 1992 through 1 May 1992

Animal assignment and treatment

AMPA was tested for its sensitising effect on the skin of the guinea pig using the Maximisation test according to Magnusson and Kligman. Female Dunkin Hartley guinea pigs with body weights ranging from 379 to 484 grams were used. The test substance concentrations for the main study were selected based on the results of the pre-testing. The main study was performed in 20 test animals.

Table 5.8.1-18: AMPA: Magnusson-Kligman Maximisation Test in Guinea Pigs ([redacted], 1993): Animal distribution

	Number of Animals Per Group
Pretest	
Intradermal Pretest	2

Epidermal Pretest	2
Main Study	
Negative Control Group	20
Test Group	20
Challenge Dose Ranging Group	4

The induction phase consisted of 6 injections consisting of two lines of three injections on each side of and parallel to the mid-line. The injections consisted of 0.1 mL Freund's Complete Adjuvant (FCA) (anterior injection), 0.1 mL test material (middle injection), and 0.1 mL of 50:50 emulsion of test material in Freund's Complete Adjuvant (posterior injection). The test material was injected at a concentration of 10 % w/v in CMC. The concentration of AMPA in Freund's Complete Adjuvant was also 10 %. Six days after the injection phase, the application area was shaved and exposed skin was wetted with 10 % aqueous sodium lauryl sulfate in order to induce local irritation. On Day 7, an epidermal application was made and the test material was topically applied at a concentration of 25 % w/v in CMC to the same pre-treated area and covered with an occlusive dressing, which was left in place for 48 hours.

Two weeks after the topical induction, test and control animals were challenged with an occlusive patch containing the test material at a concentration of 25 % w/v in CMC and with vehicle (i.e., CMC). Patches were held in place for 24 hours using the same method as topical induction.

The 4 animals intended for the dose ranging for challenge were each administered 0.1 mL intradermal injection of Freund's Complete Adjuvant on either side of the mid-line of the shaved scapular region. During the challenge period, these animals remained untreated.

For the control group, animals were treated similarly to test animals but were administered CMC instead of the test material.

According to the study report, the sensitivity of this strain of guinea pig to a known sensitizer, 2,4-dinitrochlorobenzed, is checked at 6 month intervals. The most recent positive control test was completed on 23 December 1991, in which 67 % of the test group reacted positively.

Body weights were measured at the start of the study and at study termination. Clinical signs of toxicity also were recorded

Any animal showing erythema at the site of challenge was considered to have shown a positive response.

II. RESULTS AND DISCUSSION

A. MORTALITY

One control animal died during the study.

B. CLINICAL OBSERVATIONS

Clinical signs of toxicity were limited to pale extremities.

C. BODY WEIGHT

Body weights were considered acceptable.

D. NECROPSY

A necropsy was not performed.

E. SKIN REACTIONS

No skin reactions were observed 24 or 48 h after the challenge treatment with AMPA in the control or test group.

Table 5.8.1 19: AMPA: Magnusson-Kligman Maximisation Test in Guinea Pigs ([redacted], 1993): Number of animals with positive signs following challenge

	Challenge at 25 %	
	24 hours	**48 hours**
Test Group	0/20	0/20
Negative Control Group	0/20	0/20
Challenge Dose Ranging Group	0/4	0/4

III. CONCLUSIONS

There is no evidence from the test results that AMPA is a skin sensitiser in guinea pigs. AMPA is classified as a weak sensitiser according to the Magnusson-Kligman classification.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In a study conducted in accordance with OECD 406 guidelines, AMPA is not considered a skin sensitiser based on the results of a guinea pig maximisation test. The study is considered reliable because of its adherence to current study guidelines.

Assessment and conclusion by RMS:

Short-term toxicity

1. Information on the study

Data point	CA 5.8.1/013
Report author	[redacted]
Report year	1978
Report title	Fourteen Day Rat Feeding
Report No	401-026
Document No	NA
Guidelines followed in study	No guideline followed.
Deviations from current test guideline (OECD 407, 2008)	No guidelines exist for 14 day feeding studies. When compared with OECD 407 (28 day oral toxicity) there was an absence of details for housing conditions and the certificates of analysis were not presented. In addition, stability and the certificate of analysis for the test substance

	were not identified. Only 5 animals per sex / group were employed. Oestrus cycle of females was not determined at necropsy. Haematology and clinical chemistry were not investigated. Full detailed gross necropsies and histopathology were not performed.
Previous evaluation	Not accepted in RAR (2015)
GLP/Officially recognised testing facilities	No formal claim of compliance with GLP or specific guidelines since the study was performed pre-GLP.
Acceptability/Reliability	Supportive
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary

Executive summary

In a 14 day dietary study in Charles River CD rats, the test material (CP 50435) was administered at dosage levels of 1000, 2000 and 4000 mg/kg bw/day. Five male and 5 female rats were used at each dose level and also in the control group. Rats were observed twice daily for overt signs of toxicity or mortality. Detailed observations were recorded weekly. Individual body weights and food consumption were recorded weekly.

Red coloured material in the urine was noted for 1 male rat at the 4000 mg/kg bw/day dosage level. No other changes were seen in general behaviour and appearance.

Male rats at the 4000 mg/kg bw/day dosage level showed slight to moderate decreases in body weight gain when compared with control and other treated rats. Food consumption was very slightly decreased for rats at the 4000 mg/kg bw/day dosage level.

None of the rats died during the study.

No gross lesions considered to be related to compound intake were seen at necropsy.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	"CP 50435; Aminomethyl Phosphonic Acid; Notebook Page 1219342-B; 99.9 % assay 7/7/77"
Description:	White granular material with a few yellowish crystalline chunks
Lot/Batch #:	Not specified
Purity:	99.9 %
Stability of test compound:	Not reported

2. Vehicle and/ or positive control: Purina® Laboratory Chow® / none

3. Test animals:

Species:	Rat
Strain:	Charles River CD®
Source:	[redacted]
Age:	Not specified.

Sex:	Male and female	
Weight at dosing:	♂ 90 – 113 g; ♀ 85 – 98 g	
Acclimation period:	Not specified.	
Diet/Food:	Purina® Laboratory Chow®, *ad libitum*	
Water:	Tap water, *ad libitum*	
Housing:	Individual housing in hanging wire-mesh cages	
Environmental conditions:	Temperature:	Not reported
	Humidity:	Not reported
	Air changes:	Not reported
	Light cycle:	Not reported

B. STUDY DESIGN AND METHODS

In life dates: 1977-11-25 (start of dosing) to 1977-12-09 (terminal necropsies)

Animal assignment and treatment

The test material (CP 50435) was administered in the diet at varying concentrations to provide dosage levels of 1000, 2000 and 4000 mg/kg bw/day. Five male and 5 female rats were used at each dose level and also in a control group. Control rats received the basal diet, Purina® Laboratory Chow® on the same regimen as treated rats.

Table 5.8.1-19: Fourteen Day Rat Feeding Study [redacted]-77-309 ([redacted], 1978): Study design

Test group	Dose Group [mg AMPA/kg bw/day]	Number of Rats	
		Males	Females
Control	0	5	5
Low	1000	5	5
Intermediate	2000	5	5
High	4000	5	5

The compound was ground in a mortar with pestle prior to weighing. The appropriate amount of compound was then mixed with a small amount of basal diet in a Hobart food mixer. This premix was mixed with the total amount of diet in a twin shell blender (with an intensifier bar). The diets were mixed weekly.

Diet Samples

A sample of the compound of approx. 42.5 g (equivalent to 1.5 ounce) was taken at the start of the study and at the end of the study. Weekly samples of control feed and each treatment diet were taken on day 1 of feeding. Additional containers with feed from each diet level were placed in an empty cage at the beginning of each feeding week and sampled at the end of the week. The diet samples were immediately frozen for shipping to the sponsor after termination of the study.

Mortality

The animals were observed twice daily for mortality and signs of overt toxicity.

Clinical observations

Detailed observations of each rat were recorded weekly.

Body weight

Individual body weights were recorded weekly.

Food consumption

Individual food consumption was recorded weekly.

II. RESULTS AND DISCUSSION

A. GENERAL BEHAVIOUR, APPEARANCE AND SURVIVAL

Red coloured material in the urine was noted for 1 male rat at the 4000 mg/kg bw/day dosage level. No other changes were seen in general behaviour and appearance. No rats died during the study.

B. BODY WEIGHT

Male rats at the 4000 mg/kg bw/day dosage level showed slight to moderate decreases in body weight gain when compared with control and other treated rats. Changes in body weight were similar for control and treated female rats. Group mean body weights at study initiation and termination are presented below (see table below).

Table 5.8.1 21: Fourteen Day Rat Feeding Study [redacted]-77-309 ([redacted], 1978): Intergroup comparison of group mean body weights and body weight gain

Dosage Group [mg/kg bw/day]	Mean body weight [g]		
	Week 0	Week 2	Percentage Increase [%]
	Males		
0 (control)	99	193	94.9
1000	101	203	101.0
2000	103	193	87.4
4000	105	183	74.3
	Females		
0 (control)	94	152	61.7
1000	92	149	62.0
2000	95	156	64.2
4000	91	143	57.1

C. FOOD CONSUMPTION

Food consumption was very slightly decreased for rats at the 4000 mg/kg bw/day dosage level. Group mean food and compound consumptions for the study are presented below:

Table 5.8.1-20: Fourteen Day Rat Feeding Study [redacted]-77-309 ([redacted], 1978): Intergroup comparison of mean food consumption and test substance intake

Dosage Group [mg/kg bw/day]	Average Food Consumption [g/rat/day]		Compound Consumption [mg/kg bw/day]	
Males	**Week 1**	**Week 2**	**Week 1**	**Week 2**
0 (control)	19.7	23.4	-	-
1000	20.6	24.2	1068	1090
2000	20.1	24.2	2195	2232
4000	18.5	21.1	4152	4337
Females				
0 (control)	16.4	19.1	-	-
1000	16.9	19.2	1063	1059
2000	17.4	19.0	2139	1990
4000	15.6	17.9	4070	4303

D. NECROPSY FINDINGS

Raised, opaque corneal foci were seen in one male rat of the Low dose group and hydrometra was observed in the uterus of one female rats of the Intermediate group. Both findings were considered to be of no toxicological relevance.
There were no other treatment-related gross pathological findings.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this 14 day dietary study in Charles River CD rats, the test material AMPA was administered at dosage levels of 1000, 2000 and 4000 mg/kg bw/day.

The study was not conducted according to any guideline or in compliance with GLP (pre-GLP). Therefore, the major deviations listed above are from the current version of OECD 407 (2008): no haematology, no clinical chemistry, no full detailed gross necropsies and histopathology.

Apart from these major deviations, the study was well conducted and can provide supplemental information for the assessment of the metabolites of glyphosate. The study is therefore considered to be only supplementary.

Dosing CD rats with AMPA via the diet did not produce any changes in general behaviour or appearance. Slight to moderate decrease in body weight gain was observed in males at 4000 mg/kg bw/day. Food consumption was very slightly decreased in male and female rats at the 4000 mg/kg bw/day dose level. One male rat at the high dose showed red coloured material in the urine.

No gross lesions considered to be compound related were observed. Due to the absence of relevant examinations such as haematology, clinical chemistry or histopathology, no reliable NOAEL could be derived from this study.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/014

Report author	[redacted]
Report year	1993
Report title	4 Week Dose Range Finding Study in Rats with Administration by Gavage
Report No	7803
Document No	148-GLY
Guidelines followed in study	No guideline followed.
Deviations from current test guideline	This study was essentially a dose range-finding study for which there are no guidelines. Haematology and clinical biochemistry parameters were not measured or evaluated. General gross pathology of organs and tissues was not performed - only selected organs and tissues were weighed, fixed or examined as detailed below. Histopathology was only performed on urinary bladder, mandibular salivary gland, sublingual salivary gland and parotid salivary gland.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

Groups of 5 male and 5 female Sprague-Dawley rats were dosed orally via a steel dosing cannula with AMPA (aminomethylphosphonic acid) at dose levels of 0, 10, 100, 350 or 1000 mg/kg bw/day.
After 4 weeks of dosing all surviving animals were killed, subjected to necropsy and had selected organs weighed.
All animals underwent histological examinations of the urinary bladder, mandibular salivary gland, sublingual salivary gland and parotid salivary gland.
The results are summarised as follows:

Mortality: There were no premature decedents.
Clinical Signs: There were no clinical signs.
Body Weight: There were no notable intergroup differences.
Food Consumption: There were no notable intergroup differences.
Water Consumption: There were no notable intergroup differences.
Organ weights: There was a slight equivocal increase in kidney weight at 350 and 1000 mg/kg bw/day in males.
Necropsy Findings: There were no notable intergroup differences.
Histological Findings: There were no notable intergroup differences.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification: AMPA (Aminomethylphosphonic acid)
Description: White Powder

Lot/Batch #:	286-JRJ-73-4
Purity:	99.2 %
Stability of test compound:	The test substance is stable at least 3 years from the date of analysis at ambient temperature in the dark.
2. Vehicle and/ or positive control:	0.5 % Carboxymethylcellulose (CMC) in distilled water / none
3. Test animals:	
Species:	Rat
Strain:	Sprague-Dawley
Source:	[redacted]
Age:	Approx. 4 weeks
Sex:	Male and female
Weight at dosing:	♂ 209 – 230 g; ♀ 156 – 162 g
Acclimation period:	16 days
Diet/Food:	SQC Expanded Maintenance Diet No. 1 Rat and Mouse (pelleted), *ad libitum,*
Water:	Tap water, *ad libitum*
Housing:	2 of one sex or 1 animal/cage in polypropylene cages with stainless steel wire grid tops and bottoms (420 × 270 × 200 mm).

B. STUDY DESIGN AND METHODS

In life dates: 1992-02-20 (start of dosing) to 1992-03-19 (terminal necropsies)

Animal assignment and treatment

In a 4 week dose range finding study groups of 5 Sprague-Dawley rats per sex received daily doses of 0, 10, 100, 350 or 1000 mg/kg bw/day, orally via steel dosing cannula, at a dose volume of 10 mL/kg bw for 28 consecutive days. The dose formulations were prepared fresh daily using 0.5 % carboxymethylcellulose (CMC) in distilled water as vehicle. Samples of formulations for all dosing groups (including Control) were analysed during Weeks 1 and 4 of dosing for the concentration of test item in the suspension. In addition, data demonstrating 24 hour stability of dosing suspensions were generated during the study.

Table 5.8.1-21: 4 Week Dose Range Finding Study in Rats with Administration by Gavage ([redacted], 1993): Study design

Test group	Dose Group [mg AMPA/kg bw/day]	Animal Numbers	
		Males	Females
Control	0	1 – 5	26 – 30
Low	10	6 – 10	31 – 35
Intermediate I	100	11 – 15	36 – 40
Intermediate II	350	16 – 20	41 – 45
High	1000	21 – 25	46 – 50

Mortality
All animals were checked for viability/mortality early each morning and as late as possible each day.

Clinical observations
All animals were examined for signs of reaction to treatment each day. All animals received a detailed clinical examination once each week.

Body weight
The body weight of each animal was recorded on three occasions over a 10 day pre-trial period and daily from the start of treatment until the end of the study.

Food consumption
The quantity of food consumed by each cage of animals was recorded on three occasions over a 10 day pre-trial period and twice each week from the start of treatment until the end of the study.

Water consumption
Water consumption was monitored by visual inspection throughout the treatment period.

Terminal studies
After 28 consecutive days of treatment, all surviving animals were killed by carbon dioxide asphyxiation followed by exsanguination. Gross dissection and necropsy were performed under the supervision of a pathologist.

The following organs were weighed and fixed: Liver, heart, kidneys, lung, spleen, testes, ovaries, mandibular salivary gland, sublingual salivary gland and parotid salivary gland.

The following organs were fixed and examined histologically: Urinary bladder, mandibular salivary gland, sublingual salivary gland and parotid salivary gland.

The following organs were fixed: Abnormal tissue and ears.

The above tissues were fixed in 10 % neutral buffered formalin. Lungs were fixed in their entirety by perfusion with 10 % neutral buffered formalin.
Ears were fixed for identification purposes.

Histological evaluation of the urinary bladder, mandibular salivary gland, sublingual salivary gland and parotid salivary gland was performed for all animals.

Carcasses of all animals were discarded immediately following necropsy and placing of all tissues in fixative as identified above.

Statistics
Organ weight and body weight data were statistically analysed for homogeneity of variance using the F-max test. If group variances appeared homogeneous a parametric ANOVA was used and pairwise comparisons made via Student's t-test using Fisher's F-protected LSD. If variances were heterogeneous log or square root transformations were used in an attempt to stabilise the variances. If variances were still heterogeneous, a non-parametric test such as a Kruskal-Wallis ANOVA was used and pairwise comparisons made via Dunn Z test where considered appropriate.

Organ weights were also analysed conditional on body weight (i.e. analysis of covariance).

Histological data were analysed using Fisher's Exact Probability test.

II. RESULTS AND DISCUSSION

A. MORTALITY
There were no premature decedents.

B. CLINICAL OBSERVATIONS
There were no clinical signs observed throughout the dose groups in either sex.

C. BODY WEIGHT
There were no notable intergroup differences in male animals.

A slight reduction in overall group mean body weight gain (13 %) was noted in High dose females (see table below), however, due to the small magnitude of difference and lack of statistical significance at any time point, this reduction was considered not to be related to treatment with AMPA.

Table 5.8.1-22: 4 Week Dose Range Finding Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of group mean body weights and body weight gain

Time point	Mean body weight or body weight gain [g]		
	Initial body weight	Final body weight	Total weight gain Day 0 – 28
Dose [mg/kg bw/day]	**Males**		
0	215	406	191
10	220	399	179 (94 % of Control)
100	209	420	211 (110 % of Control)
350	230	420	190 (99 % of Control)
1000	220	414	194 (102 % of Control)
	Females		
0	162	254	92
10	159	258	99 (108 % of Control)
100	156	244	88 (96 % of Control)
350	162	257	95 (103 % of Control)
1000	160	240	80 (87 % of Control)

D. FOOD CONSUMPTION
There were no notable intergroup differences for food consumption in either sex.

E. WATER CONSUMPTION
There were no notable intergroup differences for water consumption in either sex.

F. TERMINAL STUDIES

Organ weights
In males, absolute organ weights showed no notable intergroup differences.
Following covariance analysis a slight increase in kidney weight was observed for the Intermediate II and High dose groups (7 %, $p<0.05$ and 8 %, $p<0.05$, respectively). In addition, a slight increase in liver weight (10 %, $p<0.05$) was noted in the Intermediate II dose group, however, due to an absence of similar effect observed in the High dose group, this increase was considered not to be related to treatment with AMPA.

In females, there were no notable intergroup differences.

Table 5.8.1-23: 4 Week Dose Range Finding Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of selected relative mean organ weights (mean ± SE)

Organ [g]	Dose Groups [mg AMPA/kg bw/day]									
	Males					Females				
	0	10	100	350	1000	0	10	100	350	1000
Kidney (covariance analysis)	3.16 ± 0.06	3.26 ± 0.06	3.01 ± 0.06	**3.37* ± 0.06**	**3.40* ± 0.06**	2.03 ± 0.09	2.13 ± 0.09	2.16 ± 0.09	2.12 ± 0.09	2.19 ± 0.09
Liver (covariance analysis)	17.67 ± 0.54	18.91 ± 0.54	17.18 ± 0.54	**19.44* ± 0.54**	18.06 ± 0.53	10.78 ± 0.39	11.10 ± 0.40	10.98 ± 0.40	10.41 ± 0.40	9.88 ± 0.40

*: Statistically significant from controls, p<0.05

Gross pathology
Enlargement of the submandibular lymph node was seen in all dose groups (including Controls) except for male animals in the Intermediate II dose group. The incidence varied and despite being highest in the High dose females (5 / 5 compared with 1/5 in the Control) this finding was considered not to be related to treatment with AMPA.
There were no other notable intergroup differences.

Table 5.8.1-24: 4 Week Dose Range Finding Study in Rats with Administration by Gavage ([redacted], 1993): Summary of necropsy findings

Finding	Dose Groups [mg AMPA/kg bw/day]									
	Males					Females				
	0	10	100	350	1000	0	10	100	350	1000
Submandibular salivary lymph node: enlarged	3 / 5	1 / 5	2 / 5	0 / 5	1 / 5	1 / 5	3 / 5	3 / 5	3 / 5	5 / 5

Histopathology
In males, very mild reduced serous secretion in the mandibular salivary gland was noted in 1 / 5 animals in the High dose group. The change was seen as reduced eosinophilic droplets in the epithelial cells of the serous duct acini. The finding was confirmed by staining with the PAS-Alcian blue method for mucopolysaccharides. This very mild reduced serous secretion does not resemble salivary gland changes seen in long-term studies with Glyphosate (parent compound of AMPA) and was considered not to be related to treatment with AMPA.

In females, no histological changes were seen.

Table 5.8.1-25: 4 Week Dose Range Finding Study in Rats with Administration by Gavage ([redacted], 1993): Summary of histological findings

Finding	Dose Groups [mg AMPA/kg bw/day]									
	Males					Females				
	0	10	100	350	1000	0	10	100	350	1000
Salivary gland: Mandibular: reduced serous secretion	0 / 5	0 / 5	0 / 5	0 / 5	1 / 5	0 / 5	0 / 5	0 / 5	0 / 5	0 / 5

III. CONCLUSIONS

Dosing of Sprague-Dawley rats orally by gavage for 4 weeks with AMPA did not produce in-life signs of

toxicity. Organ weight analysis revealed a slight equivocal increase in kidney weight after covariance analysis at 350 and 1000 mg/kg bw/day in males. There were no toxicologically significant effects seen at 10 or 100 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this 4 week dose range finding study groups of 5 Sprague-Dawley rats per sex received daily doses of AMPA at 0, 10, 100, 350 or 1000 mg/kg bw/day by gavage for 28 consecutive days.
The study was conducted in compliance with GLP regulations. Deviations could not be applied as no guideline was followed.
However, the study was well conducted, in compliance with GLP and thus, can provide useful information for the assessment of the metabolites of glyphosate. The study is therefore considered valid.

Dosing of Sprague-Dawley rats orally by gavage for 4 weeks with AMPA did not produce in-life signs of toxicity. Organ weight analysis revealed a slight equivocal increase in kidney weight after covariance analysis at 350 and 1000 mg/kg bw/day in males.

There were no toxicologically significant effects seen at 10 or 100 mg/kg bw/day. Based on the slightly higher kidney weight in male rats, the NOAEL for AMPA can be set at 100 mg/kg bw/day in this dose range finding study.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.8.1/015
Report author	[redacted]
Report year	1991
Report title	One Month Study of AMPA Administered by Capsule to Beagle Dogs
Report No	[redacted]-11127
Document No	NA
Guidelines followed in study	US EPA Pesticide Assessment Guidelines, Subdivision F, FIFRA, Hazard Evaluation: Human and Domestic Animals, Section 82-1 and also the OECD Toxicity Test Guidelines (ISBN 92-64-12221-4, Section 409; 1981)
Deviations from current test guideline (OECD 409, 1998)	Ophthalmology not performed. Urinalysis not investigated. The following organ weights were not determined: Gall bladder, epididymides, ovaries, uterus and thymus. No histopathological examination of relevant tissues performed (all gross lesions, liver with gall bladder, kidneys, adrenals, testes, epididymides, ovaries, uterus, thyroid (with parathyroids), thymus, spleen, brain, heart, pituitary, eyes, oesophagus, salivary glands, stomach, small and large intestines, pancreas, trachea and lungs, aorta, accessory sex organs, female mammary gland, prostate, lymph nodes, peripheral nerve and bone marrow).
Previous evaluation	Not accepted in RAR (2015)
GLP/Officially recognised	Yes

Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary
Executive summary

AMPA was administered by capsule to groups of 2 beagle dogs/sex at dosages of 0, 10, 30, 100, 300 or 1000 mg/kg bw/day. Clinical observations were performed at least weekly with additional clinical signs documented by exception. Body weights and food consumption were determined weekly. Clinicopathologic examinations including haematology and clinical blood chemistry were performed at termination (1 month). All survivors were sacrificed at termination and given a complete necropsy (including weighing of selected organs). No tissues were retained.
Haematological changes at 100 mg/kg bw/day included decreased RBC counts, increased reticulocyte counts, decreased haemoglobin and decreased haematocrit in both sexes. Haematologic changes at 300 mg/kg bw/day included decreased reticulocyte counts, haematocrit and haemoglobin in females. These changes were indicative of a mild to moderate anaemia which was of undetermined aetiology.
No other signs of toxicity were observed in this study.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	AMPA (Aminomethylphosphonic acid) / EHL Substance Identification Code: T900031
Description:	White powder
Lot/Batch #:	HET-9001-1463T
Purity:	94.38 %
Stability of test compound:	Not reported.
2. Vehicle and/or positive control:	Empty gelatine capsule / none
3. Test animals:	
Species:	Dog
Strain:	Beagle
Source:	[redacted]
Age:	Approx. 6 months
Sex:	Male and female
Weight at dosing:	♂ 7.3 – 9.8 kg; ♀ 5.9 – 8.4 kg
Acclimation period:	41 days
Diet/Food:	Purina Mills Certified Canine Diet Meal #5007 (offered 1 – 2 hours each day)
Water:	Tap water, *ad libitum*
Housing:	Individual housing in stainless steel cages

Environmental conditions:	Temperature:	Not reported
	Humidity:	Not reported
	Air changes:	Not reported
	Light cycle:	Not reported

B. STUDY DESIGN AND METHODS

In life dates: 1990-04-04 (start of dosing) to 1990-05-03 (terminal necropsies)

Animal Assignment and Treatment:

AMPA was administered to groups of 2 beagle dogs/sex at dosages of 0, 10, 30, 100, 300 or 1000 mg/kg bw/day.

Neat test material was put into gelatine capsules and administered orally.

Table 5.8.1-5.8.1-26: One Month Study of AMPA Administered by Capsule to Beagle Dogs ([redacted], 1991): Study design

Group Number	Dose Group [mg AMPA/kg bw/day]	Number of Animals	
		Males	Females
1	0	2	2
2	10	2	2
3	30	2	2
4	100	2	2
5	300	2	2
6	1000	2	2

No analysis was performed to verify identity, purity or stability or otherwise characterise the test material.

In-life Observations

Checks for mortality, moribundity and noteworthy signs of toxicity were performed twice daily (AM and PM; documented by exception). Detailed observations for signs of toxicity were performed once weekly.

Body Weight

Body weights were recorded prior to randomisation and once weekly thereafter.

Food Consumption

Food consumption was analysed on a weekly basis by extrapolation from four or five-day determination of actual food consumption each week.

Ophthalmoscopic Examination

Not performed.

Clinical Pathology

At termination, all animals had blood samples collected from the jugular vein for haematology and blood chemistry determinations.

Haematology

The following parameters were evaluated: Total erythrocyte count, total leukocyte count, platelet count, haematocrit, haemoglobin, mean corpuscular volume, mean corpuscular haemoglobin, mean corpuscular haemoglobin concentration and activated partial thromboplastin time (APTT).

For leukocyte differential, blood smears were prepared on glass slides, stained with Wright's stain, and examined microscopically.

For reticulocyte count, a portion of the EDTA-treated blood sample was mixed with vital stain (methylene blue) and a slide was prepared and examined microscopically.

Blood Chemistry
The following parameters were evaluated: Albumin, total protein, blood urea nitrogen, total bilirubin, direct bilirubin, glucose, glutamic pyruvic transaminase, alkaline phosphatase, glutamic oxaloacetic transaminase, gamma glutamyl transpeptidase, creatinine, cholesterol, calcium, phosphorus, chloride, sodium, potassium and globulin.

Gross Pathology
All animals were subjected to an external and internal examination. Internal cavities were opened and the organs were examined in situ and then removed. Hollow organs were opened and examined.

Organ Weights
The following organs were weighed: Adrenals, brain, heart, kidneys, liver, spleen, testes and thyroids.
No tissues were retained or fixed.

Statistics
Because there were only two animals of each sex in each treatment group, statistical analysis often could not be performed or was inappropriate. When it was, the following statistical procedures were used to detect statistically significant differences between treated animals and their respective controls:

Dunnett's Multiple Comparison Test (two-tailed): In-life body weights, cumulative body weight changes, food consumption and APTT.

EHL decision tree analysis: Haematology data, clinical chemistry data, terminal body weights, absolute organ weights and organ/body weight ratios were evaluated by decision-tree statistical analyses which, depending on the results of tests for normality and homogeneity of variances, chose either parametric or nonparametric routines to detect differences and analyse for trend.

II. RESULTS AND DISCUSSION

A. MORTALITY
There were no unscheduled deaths in this study.

B. CLINICAL OBSERVATIONS
Diarrhoea was observed in both males and one female at 100 mg/kg bw/day (total of 18 incidents) and emesis was observed in both females and one male at 1000 mg/kg bw/day (total of 4 incidents).

C. BODY WEIGHT
There were no effects on body weight.

D. FOOD CONSUMPTION
There were no effects on food consumption.

E. CLINICAL PATHOLOGY

Haematology
Haematologic changes at 1000 mg/kg bw/day included decreased red blood cell counts, increased reticulocytes, decreased haemoglobin and decreased haematocrit in both sexes. Haematologic changes at 300 mg/kg bw/day included decreased reticulocyte counts, haematocrit and haemoglobin in females.
Statistically significant decreases in APTT in females at all dose levels were minor in magnitude and were not considered toxicologically significant.

Table 5.8.1-5.8.1-27: One Month Study of AMPA Administered by Capsule to Beagle Dogs ([redacted], 1991): Intergroup comparisons of selected group mean haematology parameters

Dose Group [mg/kg bw/day]	Group Mean Haematology Parameters

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

Blood chemistry

There were no effects on blood chemistry parameters.

G. GROSS PATHOLOGY

There were no effects on organ weights and there were no necropsy observations which were considered related to administration of the test material.

3. Assessment and conclusion

Assessment and conclusion by applicant:

AMPA was administered orally (via capsule) to groups of 2 beagle dogs/sex at dosages of 0, 10, 30, 100, 300 or 1000 mg/kg bw/day for a period of one month.
The study was conducted according to OECD 408 (1981) and in compliance with GLP. However, there were major deviations to current standards: no ophthalmology, no urinalysis, no histopathology.
Apart from these major deviations, the study was well conducted and can provide supplemental information for the assessment of the metabolites of glyphosate. The study is therefore considered to be only supplementary.
There were no mortalities or treatment related effects upon clinical observations, body weight, food

consumption, blood chemistry, organ weights or necropsy in either sex.
At 1000 mg/kg bw/day decreased erythrocyte counts, increased reticulocyte counts and decreased haematocrit was observed in both sexes.
At 300 mg/kg bw/day decreased reticulocyte counts, haematocrit and haemoglobin was observed in females. These changes were indicative of mild to moderate anaemia of undetermined aetiology.
No other signs of toxicity were observed in this study.
Under the conditions of this study, the No-Observed-Adverse-Effect-Level (NOAEL) was considered to be 300 mg/kg bw/day in male and 100 mg/kg bw/day in female Beagle dogs, respectively.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/016
Report author	[redacted]
Report year	1993
Report title	13 Week Toxicity Study in Rats with Administration by Gavage
Report No	7866
Document No	152-GLY
Guidelines followed in study	US EPA Pesticide Assessment Guidelines Subdivision, FIFRA, 82-1, in general accordance with OECD 408 (1981)
Deviations from current test guideline (OECD 408, 2018)	Functional observation and/or sensor reactivity assessments were not performed. Platelet count not included within haematology parameters. Total cholesterol, HDL, LDL and urea were not evaluated as part of clinical chemistry parameters. In addition, only 2 liver enzymes (AST and ALT) were measured. T4, T3 and TSH were not measured. Vaginal smears for oestrus cycle determination of females not performed at necropsy.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

Groups of 10 male and 10 female Sprague-Dawley rats were dosed orally each day for 13 weeks with AMPA (aminomethylphosphonic acid) at dose levels of 0, 10, 100 or 1000 mg/kg bw/day via a steel dosing cannula.

Blood samples were taken from all animals during Week 13 for investigations of haematology and clinical chemistry parameters. An ophthalmoscopic examination was undertaken on all animals during pre-trial and on all Control and High dose animals during Week 12.
On completion of 13 weeks dosing all surviving animals were killed and necropsied. Premature decedents were also necropsied. Histological examination was carried out on a full list of organs from all Control and

High dose animals and all premature decedents. In addition, histological examination was carried out on the kidneys, liver, lungs, submaxillary salivary gland, sublingual salivary gland and parotid salivary gland of all other animals.

There were 4 premature deaths (one intermediate dose male, one low dose female and two intermediate dose females). None of these deaths were due to administration of AMPA.

Clinical Signs:	There were no notable clinical signs.
Body Weight:	There were no notable intergroup differences.
Food Consumption:	There were no notable intergroup differences.
Water Consumption:	There were no notable intergroup differences.
Haematology:	There were no notable intergroup differences.
Clinical Chemistry:	There were no notable intergroup differences.
Organ weights:	There were no notable intergroup differences.
Necropsy Findings:	There were no necropsy findings which were considered to be due to treatment with AMPA.
Histological Findings:	There were no histological findings which were considered to be due to treatment with AMPA.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	AMPA (aminomethylphosphonic acid)
Description:	White Powder
Lot/Batch #:	286-JRJ-73-4
Purity:	99.2 %
Stability of test compound:	The test substance is stable at least 3 years from the date of analysis at ambient temperature in the dark.

2. Vehicle and/or positive control: 0.5 % Carboxymethylcellulose (CMC) in distilled water / none

3. Test animals:

Species:	Rat
Strain:	Sprague-Dawley
Source:	[redacted]
Age:	approx. 4 weeks
Sex:	Male and female
Weight at dosing:	♂ 144 – 168 g; ♀ 106 – 129 g
Acclimation period:	13 days
Diet/Food:	Rat and Mouse (modified) No. 1 Diet SQC (pelleted), *ad libitum,* (except for laboratory investigation sampling during Week 13 where animals were deprived of food overnight)
Water:	Tap water, *ad libitum*
Housing:	2 of one sex per cage in polypropylene cages with stainless steel wire grid tops and bottoms (420 × 270 × 200 mm).

Environmental conditions: Temperature: 20 °C
Humidity: 50 ± 15 %
Air changes: 15 – 20 / hour
12 hours light / dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 1992-04-16 (start of dosing) to 1992-07-17 (terminal necropsies)

Animal assignment and treatment:
In a 13 week oral toxicity study groups of 10 Sprague-Dawley rats per sex received daily doses of 0, 10, 100 or 1000 mg/kg bw/day, via gavage, at a dose volume of 10 mL/kg bw. The dose formulations were prepared fresh daily using 0.5 % carboxymethylcellulose (CMC) in distilled water as vehicle. Samples of formulations for all dosing groups (including Control) were analysed during Weeks 1, 6 and 13 of dosing for the concentration of test item in the suspension.

Table 5.8.1-28: 13 Week Toxicity Study in Rats with Administration by Gavage ([redacted], 1993): Study design

Test group	Dose Group [mg AMPA/kg bw/day]	Animal Numbers	
		Males	Females
Control	0	1 – 10	41 – 50
Low	10	11 – 20	51 – 60
Intermediate	100	21 – 30	61 – 70
High	1000	31 – 40	71 – 80

Mortality
All animals were checked for viability/mortality early each morning an as late as possible each day.

Clinical observations
All animals were examined for signs of reaction to treatment each day. All animals received a detailed clinical examination once each week.

Body weight
The body weight of each animal was recorded once each week before treatment and weekly from the start of treatment until the end of the study.

Food consumption
The quantity of food consumed by each cage of animals was recorded once each week before treatment and weekly from the start of treatment until the end of the study.

Water consumption
Water consumption was monitored by visual inspection throughout the treatment period.

Ophthalmoscopic examination
The eyes of all animals from all dose groups were examined during pretrial and of all Control and High dose animals during Week 12 of dosing. Ophthalmoscopic examinations of the anterior, lenticular and fundic areas were evaluated.

Haematology and clinical chemistry
Samples for laboratory investigation were taken from all animals during Week 13 of dosing after overnight deprivation of food. Samples for haematology were measured on whole blood taken into tubes containing EDTA. Samples for clinical chemistry were measured from plasma of whole blood taken into heparin. The

following haematological parameters were measured: Haemoglobin (Hb), red blood cell count, haematocrits, white blood cell count, clotting time, mean cell volume (MCV), mean cell haemoglobin (MCH), mean cell haemoglobin concentration (MCHC), neutrophils, lymphocytes, monocytes, eosinophils, basophils and large unstained cells.

For clinical chemistry analysis the following parameters were measured: blood urea nitrogen, glucose, aspartate aminotransferase (AST), alanine aminotransferase (ALT), sodium, potassium, chloride, total protein, albumin, albumin/globulin ratio, creatinine, calcium, phosphate and total bilirubin.

Terminal studies

After 13 weeks of consecutive treatment, all surviving animals were killed by carbon dioxide asphyxiation followed by exsanguination. Gross dissection and necropsy were performed under the supervision of a pathologist.

The following organs were weighed, fixed and examined histologically: Liver, heart, kidneys, lung, spleen, adrenal glands, thymus, testes, ovaries, prostate, uterus, brain, submaxillary (mandibular) salivary gland, sublingual salivary gland, parotid salivary gland and pituitary.

The following organs were fixed and examined histologically: Seminal vesicles, vagina, cervix uteri, spinal cord, thigh muscle, pancreas, submandibular lymph node, skin and mammary gland, urinary bladder, eyes, optic nerves, tongue, aortic arch, mesenteric lymph node, thyroids, parathyroids, trachea, oesophagus, stomach, duodenum, jejunum, ileum, caecum, colon, sciatic nerve, sternum and rib and any abnormal tissue.

The following organs were fixed: Rectum, smooth muscle (large intestine), nasal cavity and ears.

The above tissues were fixed in 10 % neutral buffered formalin. Lungs were fixed in their entirety by perfusion with 10 % buffered formalin. Testes were weighed with epididymides. Submaxillary and sublingual salivary glands were weighed together. Contracted bladders were distended with fixative with the epithelial surface examined after fixation. Optic nerves and eyes were fixed in Davidson's fluid. Thyroids (with parathyroids) were weighed after fixation. Ears were fixed for identification purposes.

Histological evaluation was performed on all animals from the Control and High dose groups in addition to any premature decedents. In addition, kidneys, livers, lungs, submaxillary salivary glands, sublingual salivary glands and parotid salivary glands were examined from the Low and Intermediate dose groups.

The stomach and intestines were opened at necropsy and the mucosal surface examined. Carcasses of all animals were discarded immediately following necropsy and placing of all tissues in fixative as identified above.

Statistics

Body weight, haematology, clinical chemistry and organ weight data were statistically analysed for homogeneity of variance using the F-max test. If group variances appeared homogeneous a parametric ANOVA was used and pairwise comparisons made via Student's t-test using Fisher's F-protected LSD. If variances were heterogeneous log or square root transformations were used in an attempt to stabilise the variances. If variances were still heterogeneous a non-parametric test such as a Kruskal-Wallis ANOVA was used.

Organ weights were also analysed conditional on body weight (i.e. analysis of covariance).

Histological data were analysed using Fisher's Exact Probability test.

II. RESULTS AND DISCUSSION

A. MORTALITY

There were 4 premature decedents (one Intermediate dose male, one Low dose female and 2 Intermediate dose females). Three of these animals were killed due to eye damage which occurred during the Week 13 orbital sinus bleed and one animal died during the bleed. None of the deaths were due to treatment with AMPA.

B. CLINICAL OBSERVATIONS

There were no notable clinical signs in either sex.

C. BODY WEIGHT

There were no notable intergroup differences in male animals.

A slight reduction was noted in the overall group mean body weight gain (16 %) of Low dose females (see table below). Comparison with Controls did not reveal any statistical significance at any time interval. Due to the lack of any effects observed in the Intermediate or High dose group females, this reduction was considered not to be related to treatment with AMPA.

Table 5.8.1-29: 13 Week Toxicity Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of group mean body weights and body weight gain

	Mean body weight or body weight gain [g]		
Time point	**Initial body weight**	**Final body weight**	**Total weight gain Time 0 – Week 13**
Dose [mg/kg bw/day]	**Males**		
0	159	512	353
10	157	495	338 (96 % of Control)
100	153	488	335 (95 % of Control)
1000	155	500	345 (98 % of Control)
	Females		
0	115	308	193
10	118	281	163 (84 % of Control)
100	118	297	179 (93 % of Control)
1000	116	298	182 (94 % of Control)

D. FOOD CONSUMPTION

There were no notable intergroup differences for food consumption in either sex.

E. WATER CONSUMPTION

There were no notable intergroup differences for water consumption in either sex.

E. OPHTHALMOSCOPY

All animals examined were considered normal.

G. HAEMATOLOGY AND CLINICAL CHEMISTRY

Haematology

In males, MCH was slightly increased in the Intermediate dose group (5 %, $p<0.05$). Due to the small magnitude of difference and absence of any effects observed in the High dose group, this change was considered not to be treatment-related.

In females, MCV was slightly reduced in the Low and Intermediate dose groups (both 3 %, $p<0.05$). However, due to the small magnitude of difference and absence of effects observed in the High dose group or in males, these changes were considered not to be related to treatment. In addition, Neutrophils were

increased (66 %, p<0.01) in Low dose group females, however, due the absence of any effects observed in the Intermediate or High dose groups this change was considered not to be related to treatment.

Table 5.8.1-30: 13 Week Toxicity Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of selected group mean haematology parameters (mean ± SD)

Parameter	Dose Groups [mg AMPA/kg bw/day]							
	Males				Females			
	0	10	100	1000	0	10	100	1000
MCH [pg]	17.5 ± 0.9	17.4 ± 0.4	**18.3* ± 0.6**	17.6 ± 1.5	19.2 ± 0.8	18.4 ± 0.5	18.6 ± 0.5	18.8 ± 0.5
MCV [fL]	49.0 ± 2.5	48.8 ± 1.3	50.4 ± 1.6	49.4 ± 3.7	52.3 ± 1.6	**50.7* ± 1.0**	50.9* ± 1.1	51.9 ± 1.8
Neutrophils [× 10^9/L]	2.23 ± 1.00	2.78 ± 1.50	2.25 ± 0.98	3.17 ± 1.39	0.98 ± 0.38	**1.63** ± 0.42**	1.06 ± 0.49	0.87 ± 0.35

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

Clinical chemistry

There were no notable intergroup differences in males.

In females, ALT was increased in the Intermediate dose group (45 %, p<0.05). Due to an absence of any effect observed in the High dose group this increase was considered not to be treatment-related.

Table 5.8.1-31: 13 Week Toxicity Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of selected group mean clinical chemistry parameters (mean ± SD)

Parameter	Dose Groups [mg AMPA/kg bw/day]							
	Males				Females			
	0	10	100	1000	0	10	100	1000
ALT [iu/L]	46 ± 10	50 ± 7	53 ± 27	38 ± 4	31 ± 6	35 ± 7	**45* ± 18**	30 ± 11

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

H. TERMINAL STUDIES

Organ weights

In males, thyroid weight was decreased in the Low dose group after correction for final body weight (13 %, p<0.01). Due to an absence of effects observed in the Intermediate or High dose groups, this decrease was considered not to be related to treatment.

In females, ovary weight was reduced in Low and Intermediate dose groups when expressed as an absolute value (14 %, p<0.05 and 17 %, p<0.05, respectively) and after correction for final body weight (14 %, p<0.05 and 17 %, p<0.05, respectively). Uterus weight was increased in Low and Intermediate dose groups when expressed as an absolute value (31 %, p<0.05 and 36 %, p<0.05, respectively) and after correction for final body weight (42 %, p<0.05 and 40 %, p<0.01, respectively). Due to an absence of any effect in the High dose group the above findings were considered not to be related to treatment. Thyroid weight was reduced in the Low dose group when expressed as an absolute value (19 %, p<0.05). Since this change was not seen after correction for final body weight and due to the lack of effect in the Intermediate or High dose groups, this reduction is considered to be due to chance. Brain weight was slightly reduced (4 %, p<0.05) and heart weight was increased (18 %, p<0.05) in the High dose group after correction for final body weight. The increase in heart weight was considered to be associated with one animal with myocardial hypertrophy which showed a marked increase in heart weight.

Table 5.8.1-32: 13 Week Toxicity Study in Rats with Administration by Gavage ([redacted], 1993): Intergroup comparison of selected absolute and relative mean organ weights

Organ/Tissue [g]	Dose Groups [mg AMPA/kg bw/day]

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

Gross pathology
There were no necropsy findings which were considered to be due to treatment with AMPA. All findings were typical of background pathology for this age and strain of rat. For some animals lesions associated with the right eye were noted, however, these were considered to be due to the blood sampling process.

Histopathology
There were no histopathological findings related to treatment. Those findings reported were typical of background pathology for rats of this age and strain.

III. CONCLUSIONS

There were no findings considered to be related to treatment with AMPA.
Brain weight was slightly reduced and heart weight increased in females receiving 1000 mg/kg bw/day. Due to the lack of any correlating findings, these changes were considered not to be reproducible.
In conclusion, dosing of Sprague-Dawley rats orally by gavage for 13 weeks with AMPA produced no effects at 10, 100 or 1000 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this study groups of 10 male and 10 female Sprague-Dawley rats were dosed orally for 13 weeks with AMPA at dose levels of 0, 10, 100 or 1000 mg/kg bw/day via gavage. The study was conducted according to OECD 408 (1981) and in compliance with GLP (no attest of the competent authority was provided). Deviations from the current version of OECD 408 (2018) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 408.
However, the study was well conducted, in compliance with GLP and OECD 408 (1981) and thus, can provide useful information for the assessment of the metabolites of glyphosate. The study is therefore considered valid.
There were no findings considered to be related to treatment with AMPA. Brain weight was slightly

reduced and heart weight increased in females receiving 1000 mg/kg bw/day. Due to the lack of any correlating findings, these changes were considered not to be reproducible. In conclusion, dosing of Sprague-Dawley rats orally by gavage for 13 weeks with AMPA produced no effects at 10, 100 or 1000 mg/kg bw/day. Thus, under the conditions of this study the NOAEL can be set at 1000 mg/kg bw/day.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/017
Report author	[redacted]
Report year	1979
Report title	90-Day Subacute Rat Toxicity Study
Report No	401-050
Document No	M-644184-01-1
Guidelines followed in study	No guideline followed but similar to OECD 408.
Deviations from current test guideline (OECD 408, 2018)	Ophthalmoscopy not performed. Functional observation and/or sensor reactivity assessments were not performed. Blood clotting time/potential not included within haematology parameters. Sodium, potassium, HDL, LDL, urea and creatinine were not evaluated as part of clinical chemistry parameters. T4, T3 and TSH were not measured. Vaginal smears for oestrus cycle determination of females not performed at necropsy. Adrenals, epididymides, prostate + seminal vesicles, uterus, thymus, spleen, thyroid and pituitary were not weighed at necropsy. Aorta, cervix, vagina, epididymides, seminal vesicles, coagulation glands, mammary gland and skin were not preserved / fixed. In addition, only one lymph node (mesenteric) was sampled and fixed. Histological assessment of the testes may not be as detailed as current guideline. Identification of the test chemical was limited.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	No formal claim of compliance with GLP or specific guidelines since the study was performed pre-GLP.
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

The test material (CP 50435) was administered in the diet to Charles River CD® weanling rats at dosage levels of 400, 1200 or 4800 mg/kg bw/day for 90 days. Each dosage level was fed to a group of 20 male and 20 female rats. The control group, containing a like number of rats, was fed only the basal laboratory diet. Water and respective diets were available *ad libitum*. The rats were observed twice daily for mortality and signs of overt toxicity. Detailed observations, individual body weights and food consumption were recorded weekly. Haematological and biochemical determinations and urinalyses were conducted at 45 and 88 days of study on 10 rats from each sex and group. Baseline values of the clinical laboratory tests were

obtained from 10 male and 10 female weanling rats sacrificed for this purpose.

No changes considered to be related to the compound were seen in general behaviour, appearance, haematological determinations and urinalyses. A moribund male rat in the control group was sacrificed in week 12. Nine rats from the control and treated groups died following the collection of blood at 45 and 88 days. The male rats at the 4800 mg/kg bw/day dosage level consumed less food and gained less body weight than the control. The difference in mean body weight between the control rats and male and female rats at the 4800 mg/kg bw/day dosage level reached statistical significance.

The lactic dehydrogenase activity (LDH) of the blood from rats at the 4800 mg/kg bw/day dosage level was higher than that of the control rats. For male rats at the 4800 mg/kg bw/day dosage level, the mean LDH activity was 48 and 145 % greater than the control value at 45 and 88 days, respectively. Similarily for the female rats at the 4800 mg/kg bw/day dosage level, the mean LDH activity was 29 and 171 % greater than the control values at 45 and 88 days, respectively.

All rats which died or were sacrificed in extremis during the course of study or which were sacrificed at scheduled termination were necropsied. A full set of tissues as specified in the protocol was examined microscopically from the control and 4800 mg/kg bw/day groups. Liver, kidneys, heart, urinary bladder and gross lesions were examined microscopically in rats from the 400 and 1200 mg/kg bw/day groups. No compound related gross pathologic lesions were observed at necropsy in any rats from the test compound (CP 50435) treated groups. Statistical variations, of undetermined biological significance, occurred in male and female group mean weights of kidneys, gonads, heart and brain at one or more dosage levels.

Microscopic changes which were considered compound related were limited to the urinary tract of rats from the 4800 and 1200 mg/kg bw/day dose groups. Several rats from the 1200 mg/kg bw/day groups and most rats from the 4800 mg/kg bw/day groups had hyperplasia of the urinary bladder epithelium. Very slight to slight hyperplasia of the epithelium of the kidney pelvis in several rats from the 4800 mg/kg bw/day group also was considered to be compound-related. No compound related urinary tract lesions were observed at the 400 mg/kg bw/day level.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	CP 50435 (Aminomethylphosphonic acid)
Description:	Grainy white crystalline powder/material
Lot/Batch #:	XHI 45 and XHI-136
Purity:	99.96 % (Lot No. XHI-136)
Stability of test compound:	Unknown
2. Vehicle and/ or positive control:	Purina® Laboratory Chow® / none
3. Test animals:	
Species:	Rat
Strain:	Charles River CD®
Source:	[redacted]
Age:	Approx. 4 weeks
Sex:	Male and female
Weight at dosing:	♂ 70 – 93 g; ♀ 67 – 90 g

Acclimation period:	7 days	
Diet/Food:	Purina® Laboratory Chow®, *ad libitum* (except during laboratory investigations for Day 45 and 88)	
Water:	Tap water, *ad libitum* (except during laboratory investigations for Day 45 and 88)	
Housing:	Individual housing in hanging wire-mesh cages	
Environmental conditions:	Temperature:	Not reported
	Humidity:	Not reported
	Air changes:	Not reported
	Light cycle:	12 hours light / 12 hours dark

B. STUDY DESIGN AND METHODS

In life dates: 1978-06-27 (start of dosing) to 1978-09-26 (terminal necropsies)

Animal assignment and treatment:
The test material (CP 50435) was fed in the diet at varying concentrations (based upon changes in body weight and food consumption) to provide the dosage levels indicated below:

Table 5.8.1-33: 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Treatment Groups

Test group	Dose Group [mg AMPA/kg bw/day]	Number of Rats	
		Males	Females
Control	0	20	20
Low	400	20	20
Intermediate	1200	20	20
High	4800	20	20

The test compound was added to ground Purina® Laboratory Chow® on a weight-to-weight basis. The appropriate amount of the test compound for each dosage level was ground with a portion of the basal diet using a mortar and pestle. This premix was combined with the remaining portion of the basal diet in a twin-shell blender. Initially, as indicated in the protocol, 6000 g of the test diet were prepared weekly and unused diets were discarded at the end of each week. Because of the shortage of test material the total amount of test diets prepared was reduced at week 10. Also, because of the shortage of test material the food consumption periods were adjusted as follows: On day 7 of study week 11, the weight of the food container and remaining food was recorded for each rat and containers and food returned to the animal cage. On day 1 of week 12, the food jars for the male rats were weighed and fresh diets were administered to them. On day 2 of week 12, the food jars for the female rats were weighed and fresh diets administered to them. Because of this, the food consumption data for week 12 was summarised in 2 parts. For the food consumption calculations of the periods ending on day 1 of week 12 for the male treatment groups and on day 2 of week 12 for the female treatment groups the body weights recorded on day 7 of week 11 were used.

Diet Samples
Samples of stored test materials were taken at the beginning of the study and at monthly intervals. Weekly samples of the control feed and each treatment diet was taken on day 1 of feeding. Additional containers of the diets were placed in empty cages at the beginning of each feeding week and sampled at the end of the week. All diet samples were frozen immediately after collection. The samples were shipped to the sponsor at monthly intervals.

Mortality
The animals were observed twice a day 7 days a week for mortality and signs of overt toxicity.

Clinical observations
Detailed observations of each rat were recorded weekly.

Body weight
Individual body weights were recorded weekly.

Food consumption
Individual food consumption was recorded weekly.

Haematology and clinical chemistry and urinalysis
10 male and 10 female rats from each dose level were selected for clinical laboratory investigations at 45 and 88 days of study. The baseline data of the clinical laboratory tests were obtained from 10 male and 10 female weanling rats similarly selected and sacrificed for this purpose. Blood samples were obtained by the orbital sinus technique from fasted rats. The urine was collected while the rats were fasting.

Haematology parameters included: Haematocrit value, haemoglobin concentration, erythrocyte count, leucocyte count (total and differential), platelet count and reticulocyte count.

Biochemistry parameters included: Fasting blood glucose, blood urea nitrogen, total cholesterol, total protein, albumin, globulin (calculated), direct and total bilirubin, serum alkaline phosphatase (SAP), serum lactic dehydrogenase (LDH), serum glutamic oxalacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT).

Urinalysis included description of colour and appearance, determination of volume, specific gravity and pH, qualitative tests for glucose, protein, ketones, bilirubin, urobilinogen and microscopic examination of sediment.

Terminal studies
At completion of the compound feeding period, all surviving rats were sacrificed by carbon dioxide asphyxiation and necropsied. At necropsy, examination was made of the external body surface and orifices and the rat was opened. Contents of the cranium, thorax and abdomen were examined *in situ*, removed, and again examined. Representative tissues of organs from each rat were collected and fixed in buffered neutral 10 % formalin. Rats which died or were sacrificed in extremis during the course of the study were necropsied as above.

The liver, kidneys, testes, heart and brain from each rats sacrificed at termination were weighed at necropsy and ovaries were weighed after fixation.

Haematoxylin and eosin stained paraffin sections of the following tissues from all rats from the control and 4800 mg/kg bw/day groups were prepared by standard histologic methods and examined microscopically: Brain, spinal cord, peripheral nerve (sciatic), eye (optic nerve), pituitary, thyroid (parathyroid), adrenals, trachea, lung/bronchi, heart, spleen, lymph node (mesenteric), thymus, sternum (bone marrow), salivary gland (submandibular), oesophagus, stomach, small intestine (duodenum, jejunum, ileum), large intestine (colon, caecum), pancreas, liver, kidneys, urinary bladder, testes/ovaries, prostate/uterus, skeletal muscle and any tissues with gross lesions.

Haematoxylin and eosin stained paraffin sections of kidneys, liver, heart, urinary bladder and tissues with gross lesions were prepared and examined from all rats from the 400 and 1200 mg/kg bw/day feeding groups.

Statistics

All statistical analyses compared the treatment groups with the control group, by sex.
Body weights (week 13), food consumption (week 13) haematological, biochemical and urinalysis parameters (days 45 and 88) and absolute and relative organ weights (terminal), were compared by analysis of variance (one-way classification), Bartlett's test for homogeneity of variances and the appropriate t-test (for unequal variances) as described by Steel and Torrie using Dunnett's multiple comparison tables to judge significance of differences.

II. RESULTS AND DISCUSSION

A. GENERAL BEHAVIOUR, APPEARANCE AND SURVIVAL

One male and five female rats at the 4800 mg/kg/day dosage level were found dead on day 45 following the collection of blood. Similarly, one female in the control group and two female rats in the 1200 mg/kg bw/day group were found dead after the collection of blood on study day 88. In addition, one male rat in the control group was sacrificed in week 12. Previous observation included soft stools, distended abdomen and morbidity. Survival after 90 days of study was a follows:

Table 5.8.1-5.8.1-34 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Intergroup comparison of group survival

Dose Level [mg/kg bw/day]	Surviving Males / No. Initiated	Surviving Females / No. Initiated
0 (control)	19/20	19/20
400	20/20	20/20
1200	20/20	18/20
4800	19/20	15/20

B. BODY WEIGHT

For both male and female rats at the 4800 mg/kg bw/day dosage level and male rats at the 1200 mg/kg bw/day dosage level, the differences in body weight from that of the control were statistically significant at 13 weeks (see table below).

Table 5.8.1-35: 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Intergroup comparison of group mean body weights and body weight gain

Dosage Group [mg/kg bw/day]	Mean body weight or body weight gain [g]		
	Initial body weight	Final body weight	Total weight change [%] Time 0 – Week 13
	Males		
0 (control)	82	480	485
400	80	480	500
1200	80	**453***	466
4800	81	**346****	327
	Females		
0 (control)	79	264	234
400	76	266	250
1200	79	274	246
4800	79	**252****	219

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

C. FOOD CONSUMPTION

Treated male rats consumed less food than the control, although when compared with control this was not shown to be statistically significant.
In increasing dosage levels the compound consumption based on food consumption for the male rats was 406, 1230 and 4989 mg/kg bw/day and for the female rats was 388, 1161 and 4625 mg/kg bw/day, respectively.

Table 5.8.1-36 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Intergroup Comparison Group Average Food Consumption

Dosage Group	Average Food Consumption [g/rat/day]	
Dose [mg/kg bw/day]	**Males**	**Females**
0 (control)	25.5	17.9
400	25.1 (-1.6)	17.8 (-0.6)
1200	25.2 (-1.2)	19.2 (7.3)
4800	23.5 (-7.8)	18.3 (2.2)

(): % difference from Control

D. CLINICAL LABORATORY TESTS

Haematology
No changes considered to be related to the compound intake were seen in the haematological determinations. For as few specific determinations there were statistically significant differences between the control and some of the treated groups. Since the individual values for the rats were within the range usually observed for Charles River rats at the test laboratory, the differences were regarded as not biologically significant.

Biochemistry
For the control and treated groups the mean values for the lactic dehydrogenase activity was greater at 45 and 88 days than for the control baseline period and the lactic dehydrogenase activities for the rats at the 4800 mg/kg bw/day dosage level were considerably greater than for the other groups.

At both 45 and 88 days the activity for the male rats at the 4800 mg/kg bw/day dosage level was greater than the range of values usually observed for Charles River rats. The differences between the mean values for these male rats and the control rats were statistically significant and the effect may be regarded as dose related. Similarly, for the male rats at the 1200 mg/kg bw/day dosage level after 88 days the increase in lactic dehydrogenase activity may be dose related. By contrast, for the other groups of rats the activities were within the expected range of values.

For the female rats the assessment is complicated by the 25 % decrease in lactic dehydrogenase activity of the control for the determinations at 45 and 88 days. This brings into question the biological significance of the differences between the female control and the female rats at 400 and 1200 mg/kg bw/day for the 88 days determination, especially since the values were within normal limits. At the 4800 mg/kg bw/day dosage level the values were definitely greater than the usual range values. Although the magnitude of the effect at 88 days appeared exaggerated by the lower control values the increase in lactic dehydrogenase activity was real and may be regarded as dose related.

Five male and four female rats at the 4800 mg/kg bw/day dosage level provided blood samples at both 45 and 88 days. For all but one female rat the values at 88 days were greater than those at 45 days.
For a few other specific determinations there were statistically significant differences between the control and some of the treated rats. Since the individual values for the rats were within the range usually observed for Charles River rats at the testing laboratory the differences were not regarded as biologically significant.

Table 5.8.1-37: 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Intergroup comparison of selected group mean biochemistry parameters

Parameter	Group Mean Lactic Dehydrogenase Activity [B-B units/mL]							
	Male [mg/kg bw/day]				Female [mg/kg bw/day]			
	0	400	1200	4800	0	400	1200	4800
LDH (Baseline)	1645	-	-	-	1361	-	-	-

Urinalysis
No changes considered to be related to the compound intake were seen in the urinalysis.

E. TERMINAL STUDIES

Organ weights
Statistically significant variances in group mean organ weights of liver, kidneys, testes / ovaries, heart and brain were noted for males and females. In the absence of compound related morphologic parenchymal changes in these organs, the biological significance of these statistical variations was undetermined.

Table 5.8.1-38: 90-Day Subacute Rat Toxicity Study ([redacted]-78-174) ([redacted], 1979): Intergroup comparison of selected absolute and relative group mean organ weights

Gross pathology
No gross pathologic lesions which were considered related to test material (CP 50435) feeding were observed at necropsy in any rats from the experimental groups. Gross pathologic lesions which were seen in these rats were those which commonly occur in untreated rats of this strain and age and were not considered significant with respect to the outcome of the study.

Histopathology
Microscopic pathologic lesions which were considered related to feeding of the test material (CP 50435)

were limited to the urinary tract of rats from the 1200 and 4800 mg/kg bw/day feeding groups. Several rats from the 1200 mg/kg bw/day feeding groups and most rats from the 4800 mg/kg bw/day group had hyperplasia of the urinary bladder epithelium. Urinary bladders of rats from the 400 mg/kg bw/day group were comparable to those of control group rats. The compound related urinary bladder hyperplasia was more marked in males than in females and in males it was occasionally accompanied by an acute inflammatory infiltrate in the mucosa and submucosa. The lesion, when present, was fairly uniform over most of the circumference of the urinary bladder and did not show papillarity.

Epithelial hyperplasia was noted in the pelvis of the kidney of a few rats in the 4800 mg/kg bw/day group. The hyperplasia had a slight papillarity and was not uniform over the entire epithelial surface. Some hyperplastic epithelial cells contained a hyaline like cytoplasmic inclusion. This lesion was considered compound related. Several other kidneys had areas of pelvic epithelium which appeared to be hyperplastic, but in these the tissue was cut such that the possibility of a tangential section of epithelium could not be eliminated.

Other microscopic findings in these rats were lesions principally of an inflammatory nature, which are commonly seen in untreated rats of this age and strain. Other microscopic lesions in the kidneys from control and experimental group animals were those of an inflammatory nature and were considered early lesions of chronic nephritis, a common spontaneous disease of laboratory rats. These inflammatory lesions were much more common in males than in females. Chronic nephritis had a greater incidence and severity in males. The fresh haemorrhage noted in the lungs of many rats from the control and 4800 mg/kg bw/day group was considered agonal due to death by carbon dioxide asphyxiation. Other lung lesions were those of a minor inflammatory or degenerative nature which are commonly seen in rats and were not considered significant with respect to treatment. Ample areas of bronchi were present for examination in sections from all rats in the control and 4800 mg/kg bw/day groups. Myocarditis noted in the heart of numerous rats from the control and treated groups was characterised by small focal accumulations of mononuclear inflammatory cells scattered throughout the myocardium. This is a common finding in rats. Changes noted in the hearts of these rats were generally quite minimal and considered typical of the degree of myocarditis ordinarily noted in rats of this age. Prostate glands of a number of rats from the control and experimental groups had slight to moderate inflammatory changes in the interstitium and within prostate follicles. This lesion is a common finding in male rats. Small focal haemorrhages observed in the thymus of many control and experimental group rats were fresh with intact red blood cells present and were considered agonal. Mild subacute inflammatory changes in the parenchyma and portal areas were seen in the livers of numerous rats from control and experimental groups. These lesions are common findings in rats. A number of rats in the control and experimental groups also had very slight extramedullary haematopoiesis in their livers. The hepatocellular vacuolation noted in livers, primarily of male rats, in the experimental and control groups were characterised by the presence of a single large vacuole which was usually not spherical but had a smooth irregular outline. Many of these vacuoles appeared to contain aluminous fluid. Their incidence was somewhat greater in the control males. They were not characteristic of the vacuoles of fatty degeneration and were not considered biologically significant in this study.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study was not conducted according to any guideline or in compliance with GLP (pre-GLP), but following a study design similar to OECD 408. Therefore, the deviations listed above are from the current version of OECD 408 (2018).
However, the study was well conducted and thus, can provide useful information for the assessment of the metabolites of glyphosate. The study is therefore considered valid.
No changes considered to be related to the compound were seen in general behaviour, appearance, haematological determinations or urinalysis.
Male rats at the 4800 mg/kg bw/day group consumed less food and gained less body weight than the control. At week 13, the difference in mean body weight gain between control rats and male and female rats at the 4800 mg/kg bw/day dosage level was statistically significant ($p<0.01$).
Lactic dehydrogenase activity (LDH) for rats at 4800 mg/kg bw/day was greater than controls. In males at 4800 mg/kg bw/day mean LDH activity was 48 and 145 % greater than controls at 45 and 88 days, respectively. In females at 4800 mg/kg bw/day mean LDH activity was 29 and 171 % greater than control values at 45 and 88 days, respectively.
No compound related gross pathologic lesions were observed at necropsy in any rats from the test compound (CP 50435) treated groups.
Statistical variations of undetermined biological significance occurred in group mean weights of kidneys, gonads, heart and brain at several dosage levels in both sexes. Most statistically significant alterations in organ weights occurred in the high dose groups, though.
Microscopic changes which were considered compound related were limited to the urinary tract of rats from the 4800 and 1200 mg/kg bw/day dose groups where hyperplasia of the urinary bladder epithelium was observed. Additionally, very slight epithelial hyperplasia was noted in the bladders of several rats from the 1200 mg/kg bw/day. Very slight to slight hyperplasia of the epithelium of the kidney pelvis in several rats from the 4800 mg/kg bw/day dose group was also considered compound related.
No compound related urinary tract lesions were observed at the 400 mg/kg bw/day level in either sex.
Based on the incidence of microscopic changes in the mid and high dose groups (urothelial hyperplasia of the urinary bladder), the NOAEL equalled 400 mg/kg bw/day under the conditions of this 90-days oral study with AMPA (CP 50435).

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.8.1/018
Report author	[redacted]
Report year	1991

Report title	90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA
Report No	[redacted]-50173
Document No	M-645465-01-1
Guidelines followed in study	US EPA Pesticide Assessment Guidelines, Subdivision F, FIFRA, Hazard Evaluation: Human and Domestic Animals, Section 82-1 and also the OECD Toxicity Test Guidelines (ISBN 92-64-12221-4, Section 409; 1981)
Deviations from current test guideline (OECD 409, 1998)	Gall bladder, uterus, thymus, spleen and heart not weighed at necropsy.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

The toxicological potential of AMPA was evaluated in this 90-day sub-chronic toxicity study in outbred beagles. Dosage levels of 10, 30, 100 and 300 mg/kg bw/day were selected for the study.

The test material was administered in capsule form as a single daily dose for 91 or 92 consecutive days. A concurrent control group received empty capsules on a comparable regimen. Each dose group consisted of five males and five females. All animals were observed twice daily for mortality and moribundity. Clinical examinations were performed daily prior to dosing and one hour following dosing. Individual body weights were recorded weekly. Food consumption was recorded daily and reported weekly. Clinical pathologic evaluations were conducted once prior to study initiation and during the 6th and 13th weeks of dosing (weeks 5 and 12). Ocular examinations were conducted prior to study initiation and during the 13th week of dosing. Complete necropsies were performed on all dogs at study termination. Selected organs were weighed and selected organs were examined microscopically.

Test article administration had no adverse effects at any dose level on survival, general clinical condition or behaviour, body weight, food consumption, clinical pathology parameters or organ weight values.
No treatment related lesions were observed neither at the ocular examinations nor following gross and microscopic examinations of selected tissues.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	AMPA (Aminomethylphosphonic acid)
Description:	White solid (powder)
Lot/Batch #:	PIT-9008-2407-T
Purity:	87.8 %
Stability of test compound:	August 1993 (Estimated Expiry). Confirmatory analysis performed by Sponsor from samples of test material at the beginning and end of the study.

2. Vehicle and/ or positive control:	Empty gelatine capsule / none
3. Test animals:	
Species:	Dog
Strain:	Outbred Beagle
Source:	[redacted]
Age:	Approx. 6 months
Sex:	Male and female
Weight at dosing:	♂ 8123 – 11929 g; ♀ 6753 – 10788 g
Acclimation period:	2 weeks
Diet/Food:	Purina® Certified Canine Chow® #5007 (offered 1 – 2 hours each day)
Water:	Tap water, *ad libitum*
Housing:	Individual housing in stainless steel cages
Environmental conditions:	Temperature: 19 – 24 °C (67 – 75 °F) Humidity: 30 – 76 % Air changes: 10 – 15 / hour 12 hours light / dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 1990-09-05 (start of dosing) to 1990-12-06 (terminal necropsies)

Animal Assignment and Treatment:
In a 90-day oral (capsule) toxicity study groups of 5 outbred beagle dogs per sex received daily doses of 0, 10, 30, 100 or 300 mg/kg bw/day, at approximately the same time each day for 91 or 92 consecutive days. Capsules were administered following the 1 – 2 hours feeding period.

Table 5.8.1-5.8.1-40 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Study design

Group Number	Dose level [mg AMPA/kg bw/day]	Dose level corrected for purity [mg/kg bw/day]	Number of Animals	
			Males	Females
1	0	0	5	5
2	10	8.8	5	5
3	30	26.3	5	5
4	100	87.8	5	5
5	300	263	5	5

The appropriate amount of test material was weighed into tared size gelatine capsules. A sufficient number of capsules were weighed for each entire week of dosing and stored. Individual dosages were adjusted weekly, based on the most recent body weight. One empty gelatine capsule was dispensed daily for each control animal.
Analysis of the test material was conducted by the Sponsor prior to the beginning and at the conclusion of the study. It was demonstrated that AMPA was stable throughout the course of the study. Results were provided by the Sponsor and presented in a separate report (Monsanto Study ML-90-369).

Mortality
All animals were observed twice daily, once each morning and once in the afternoon for mortality and moribundity.

Clinical Observations
All animals were observed daily prior to dosing and one hour following dosing for overt signs of toxicity. Only significant findings were recorded at these observations.

Body Weight
Body weights were recorded weekly for study weeks -1 – 13. Terminal body weights were recorded for each animal on the day of study termination.

Food Consumption
Individual food consumption was recorded daily and the weekly averages reported for the corresponding body weight intervals. Food intake was calculated as mg/kg bw/day.

Ophthalmoscopic Examination
Ocular examinations were conducted prior to study initiation and during the 13th week of dosing. All examinations were conducted using a hand-held slit lamp and an indirect ophthalmoscope, preceded by mydriasis with 1 % topical tropicamide hydrochloride.

Clinical Pathology
Clinical pathology parameters (haematology, serum chemistry and urinalysis) were measured on all dogs once prior to study initiation and during the 6th and 13th week of dosing (study weeks 5 and 12, respectively). Collection of blood and urine samples was conducted prior to feeding and test item administration. Blood samples were taken from the jugular vein. Urine was collected using a catheter except for the following instances where urine for re-evaluation was collected using metabolism cages (15 – 16 hours collection) for male numbers 775 and 793 in the 300 mg/kg bw/day group (weeks 5 and 12, respectively) and female number 817 in the 10 mg/kg bw/day group (week 5). Values for these animals were reported but excluded from group mean calculations.

Haematology
The following parameters were evaluated: Total leukocyte count (white cell), erythrocyte count (red blood cells), haemoglobin, haematocrit, mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC), platelet count (Platelet), prothrombin time, activated partial thromboplastin time (APTT), differential white (WBC) count (percent and absolute) for neutrophils (segmented and unsegmented), lymphocytes, monocytes, eosinophils and basophils.

Serum Chemistry
The following parameters were evaluated: Glucose, blood urea nitrogen, creatinine, sodium, potassium, serum aspartate aminotransferase (AST), chloride, calcium, globulin, albumin/globulin ratio, serum alanine aminotransferase (ALT), serum alkaline phosphatase (ALK), total bilirubin (Total Bili), total cholesterol (Cholesterol), total protein, albumin and gamma glutamyltransferase (GGT).

Urinalysis
The following parameters were evaluated: Volume, colour, appearance, specific gravity, pH, protein, glucose, ketones, bilirubin, occult blood, nitrites, leukocytes and microscopy of sediment.

Terminal Studies
Macroscopic and Microscopic Examination
At study termination, all dogs were anaesthetised by intravenous injection of sodium phenobarbital followed by exsanguination. A complete necropsy was conducted on all animals. Necropsy included, but was not limited to, examination of the external surface, all orifices, the cranial cavity, the external and cut surfaces of the brain and spinal cord, and the thoracic, abdominal and pelvic cavities including viscera.

Bone marrow smears were taken at necropsy.
The following organs and tissues were collected and placed in 10 % neutral buffered formalin: Adrenals, aorta, bone with marrow (sternum), brain (forebrain, mid-brain, hindbrain), eyes with optic nerve, femur (with joint), gall bladder, gastrointestinal tract (oesophagus, stomach, duodenum, jejunum, ileum, caecum, colon, rectum), heart, kidneys, liver (sections of 2 lobes), all gross lesions, lungs (including bronchi), lymph node (mesenteric and suprapharyngeal), ovaries with mesovarium, pancreas, peripheral nerve (sciatic), pituitary, prostate, salivary gland (submaxillary), skeletal muscle (*vastus medialis*), skin with mammary gland, spinal cord (mid-thoracic, cervical and lumbar), spleen, testes with epididymides, thymus, thyroid gland (both lobes with parathyroid gland), trachea, urinary bladder, uterus with vagina.
After fixation and following staining with haematoxylin and eosin, the above tissues were examined microscopically.

Organ Weights
The following organs were weighed from all animals: Adrenals, brain, kidneys, liver, ovaries, testes with epididymides and thyroid gland (with parathyroids).
Statistics
All means were presented with standard deviations, and the number of sampling units used to calculate the means. All statistical tests were performed by a DEC (Digital Equipment Corporation) computer with appropriate programming. Analysis of body weights, body weight changes, food consumption, clinical laboratory values and absolute and relative organ weights were analysed by a one-way analysis of variance followed by Dunnett's Test. All analyses were conducted using two-tailed tests for minimum significance levels of 5 % and 1 % comparing the treatment groups with vehicle control group by sex.

II. RESULTS AND DISCUSSION

A. MORTALITY
All animals survived to scheduled necropsy.

B. CLINICAL OBSERVATIONS
There were no clinical signs in either sex which could be positively attributed to treatment with the test material.
Numerous clinical signs were observed in both sexes at all dose levels, including controls. These consisted primarily of lacrimation, scabbed, reddened and/or swollen ears, soft stool, diarrhoea, salivation and emesis at the daily examinations prior to dosing. In general, these findings occurred at a similar frequency in the control and treated groups and/or in a non-dose-related manner, although occasional disproportionate frequencies occurred.

C. BODY WEIGHT
No treatment related effects were apparent on mean body weights or body weight changes in males and females at dose levels of 10, 30, 100 or 300 mg/kg bw/day.
A mean body weight loss in the 300 mg/kg bw/day female group during weeks 5 – 6 was greater than the loss observed in the control group. However, the severity of loss in females at 300 mg/kg bw/day was due to one female (number 801) and this loss was followed by a substantial body weight gain during weeks 6 – 7. It should be noted that during this time period, red material was found in the faeces of this animal and food intake was notably reduced, for which it was concluded that these effects were transitory and not related to treatment.
The only statistically significant difference in body weight between control and treated groups was an increase in mean body weight gain ($p<0.05$) in females at 300 mg/kg bw/day during weeks 8 – 9 (see **Error! Reference source not found.**e below). No other remarkable differences were observed in body weight data between the control and the 10, 30, 100 and 300 mg/kg bw/day dose groups.

Table 5.8.1-5.8.1-41: 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Intergroup comparison of selected group mean body weights and body weight gain

Dose Group [mg/kg bw/day]	Mean body weight or body weight gain [g]				
	Body weight (Week 0)	Body weight (Week 13)	Body weight gain (week 5 – 6)	Body weight gain (week 6 – 7)	Body weight gain (week 8 – 9)
	Males				
0	9781 ± 1147.8	11849 ± 1200.9	12 ± 214.3	431 ± 95.2	144 ± 232.4

300	8360 ± 1190.8	9759 ± 1401.6	-461 ± 507.7	554 ± 100.8	**291* ± 102.5**

*: Statistically significant from controls, p<0.05

D. FOOD CONSUMPTION

Food consumption was unaffected by treatment at any dose level.

Food consumption values (grams/animal/day and g/kg bw/day) in females at 300 mg/kg bw/day were slightly lower, but not statistically significant, than the control group during weeks 5 – 6. The decreases were due to one female (number 801) in the 300 mg/kg bw/day group, and food consumption in this group during weeks 6 – 7 was comparable to that of the control group. Therefore, the brief reduction in food consumption at this dose level was not considered to be a treatment related effect. A statistically significantly increased (p<0.05) food consumption (g/kg bw/day) was noted in females at 300 mg/kg bw/day during weeks 8 – 9. This was the only statistically significant difference in food consumption between the control and treated groups. All other values in the 10, 30, 100 and 300 mg/kg bw/day groups were comparable with the control group.

Table 5.8.1-5.8.1-42: 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Intergroup comparison of selected food consumption values (means ± SD)

Dose Group [mg/kg bw/day]	Group Mean Food Consumption				
	Food Consumption Week 5 – 6 [mg/dog/day]	Food Consumption Week 5 – 6 [g/kg bw/day]	Food Consumption Week 6 – 7 [mg/dog/day]	Food Consumption Week 6 – 7 [g/kg bw/day]	Food Consumption Week 8 – 9 [g/kg bw/day]
	Males				
0	302 ± 60.2	29 ± 7.0	343 ± 60.2	32 ± 5.7	29 ± 5.7

*: Statistically significant from controls, p<0.05

E. OPHTHALMOSCOPY

No oculopathical lesions indicative of a toxic effect were observed at any dose level.

F. CLINICAL PATHOLOGIC EVALUATION

Haematology

Haematology parameters were unaffected by test article administration in the 10, 30, 100 and 300 mg/kg bw/day group males and females.

Values in the treated groups were generally comparable to those in the control group. The following statistically significant differences were observed.

The mean MCHC value in males at 10 mg/kg bw/day was significantly reduced (p<0.01) at the week 5 evaluation when compared to the control group. Similar decreases were not observed at higher dose levels or in females at any dose level. The mean MCV value in the 10 mg/kg bw/day females was significantly reduced (p<0.05) in week 12 when compared to the control group. However, similar decreases were not observed in females at higher dose levels or in males at any dose level.

At the week 12 evaluation, significant reductions (p<0.05 or p<0.01) were observed in mean red cell count, haemoglobin and haematocrit values for males in the 30 mg/kg bw/day group, in mean haemoglobin and MCH values in the 100 mg/kg bw/day group, and in the mean MCV value in the 10 mg/kg bw/day group females. Similar findings were not observed in male or females at 300 mg/kg bw/day and no relationship to treatment was evident.

Table 5.8.1-5.8.1-43: 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Intergroup comparison of selected group mean haematology parameters (means ± SD)

Dose Group [mg/kg bw/day]	Group Mean Haematology Parameters

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

Serum chemistry
No treatment related effects were apparent on serum chemistry parameters at any dose level.
Mean glucose values were significantly higher ($p<0.05$) in the 30 and 100 mg/kg bw/day group males than in the control group males at week 12. However, this was attributed to a slightly lower control mean (91 mg/dL) at week 12 than in week 5; the means for the 30 and 100 mg/kg bw/day group males were each 101 mg/dL and identical to the week 5 control mean of 101 mg/dL.
All other serum chemistry values in the treated groups were comparable to those in the control group and week 5 and week 12.

Table 5.8.1-5.8.1-44: 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Intergroup comparison of selected group mean serum chemistry parameters

Group Mean Parameter	Dose Groups [mg AMPA/kg bw/day]									
	Males					Females				
	0	10	30	100	300	0	10	30	100	300
Glucose Week 5 [mg/dL]	101 ± 7.7	106 ± 7.2	100 ± 10.0	100 ± 10.5	103 ± 5.8	100 ± 9.0	102 ± 2.7	105 ± 8.5	101 ± 10.9	106 ± 5.0
Glucose Week 12 [mg/dL]	91 ± 4.8	95 ± 4.5	**101* ± 6.1**	**101* ± 6.5**	100 ± 5.2	91 ± 6.0	98 ± 6.8	89 ± 8.0	86 ± 4.2	85 ± 7.9

*: Statistically significant from controls, $p<0.05$; **: Statistically significant from controls, $p<0.01$

Urinalysis
No adverse effects on urinalysis parameters were observed at any dose level. None of the differences between the control and treated groups were statistically significant.

G. PATHOLOGY

Macroscopic Examination
At study termination, no treatment related lesions were noted in the 10, 30, 100 or 300 mg/kg bw/day group males and females.
The lesions observed in the treated groups were commonly observed lesions and either occurred at a similar frequency in the control or occurred infrequently (generally in a single animal).

Microscopic Examination
No microscopic lesions indicative of treatment-related effect were apparent at any dose level.
The lesions observed occurred similarly in the control and treated groups or were limited, in general, to single occurrences.

Organ weights
Test article administration did not adversely affect mean absolute organ weights and organ weights relative to final body weight in males and females at dose levels of 10, 30, 100 or 300 mg/kg bw/day.
The only statistically significant differences between the control and treated groups were low ($p<0.05$ or $p<0.01$) mean absolute and relative liver weights in the 100 mg/kg bw/day group females. Decreased liver weights were not similarly observed in females at the higher dose level of 300 mg/kg bw/day and no relationship to treatment was evident. No other remarkable difference in organ weight data were observed between the control group and the 10, 30, 100 and 300 mg/kg bw/day groups.

Table 5.8.1-5.8.1-45: 90-Day Oral (Capsule) Toxicity Study in Dogs with AMPA ([redacted], 1991): Intergroup comparison of selected absolute and relative (to body weight) mean organ weights

Organ / Tissue	Dose Groups [mg/kg bw/day]									
	Males					Females				
	0	10	30	100	300	0	10	30	100	300
Absolute Liver weight [g]	313.74 ± 47.483	320.22 ± 48.634	314.85 ± 48.712	302.04 ± 24.138	324.36 ± 44.436	294.97 ± 55.697	269.93 ± 26.698	264.46 ± 14.855	**229.85 * ± 27.905**	261.66 ± 34.830
Relative Liver weight [g/100 g]	2.658 ± 0.3631	2.553 ± 0.1949	2.657 ± 0.4170	2.470 ± 0.0920	2.653 ± 0.2288	2.921 ± 0.2044	2.728 ± 0.1532	2.688 ± 0.1518	**2.441* * ± 0.1140**	2.696 ± 0.2353

*: Statistically significant from controls, p<0.05; **: Statistically significant from controls, p<0.01

III. CONCLUSIONS

Administration of the test material AMPA had no adverse effects at any dose level on the survival, the general clinical condition or behaviour of animals, body weight data, food consumption data, haematology parameters, serum chemistry parameters, urinalysis parameters or organ weight values.
No treatment related lesions were observed at the ophthalmologic examination or at the gross and microscopic examinations of selected tissues.

Based on the results of this study, the highest dose level of 300 mg/kg bw/day administered orally to dogs for 91 or 92 consecutive days was considered to be the NOAEL (No Observed Adverse Effect Level).

3. Assessment and conclusion

Assessment and conclusion by applicant:

The test material AMPA was administered orally via capsule to Beagle dogs at dose levels of nominally 0, 10, 30, 100 and 300 mg/kg bw/day. After adjustment for purity (87.8 %) the dose levels were 0, 8.8, 26.3, 87.8 and 263 mg/kg bw/day.
The study was conducted according to OECD 408 (1981) and in compliance with GLP (no attest of the competent authority was provided). Deviations from the current version of OECD 409 (1998) are basically due to the fact that the study was aligned to an older version of the OECD test guideline 409. However, the study was well conducted, in compliance with GLP and OECD 409 (1981) and thus, can provide useful information for the assessment of the metabolites of glyphosate. The study is therefore considered valid.
Administration of the test material AMPA had no adverse effects at any dose level on the survival, the general clinical condition or behaviour of animals, body weight data, food consumption data, haematology parameters, serum chemistry parameters, urinalysis parameters or organ weight values.
No treatment related lesions were observed at the ophthalmologic examination or at the gross and microscopic examinations of selected tissues.
Based on the results of this study, the highest dose level of nominally 300 mg/kg bw/day (263 mg/kg bw/day after adjustment for purity) administered orally to dogs for 91 or 92 consecutive days was considered to be the NOAEL (No Observed Adverse Effect Level).

Assessment and conclusion by RMS:

Genotoxicity - *in vitro*

1. Information on the study

Data point	CA 5.8.1/019
Report author	[redacted]
Report year	1996
Report title	AMPA: Reverse Mutation Test
Report No	IET 96-0076
Document No	NA
Guidelines followed in study	OECD 471 (1983), OECD 472 (1983), U.S. EPA FIFRA Guidelines, Subdivision F, Japanese MAFF (1985)
Deviations from current test guideline (OECD 471, 1997)	Information on historical control data was not reported. 2-Aminoanthracene was used as sole positive control in the presence of metabolic activation. In the repeat-experiment, no parameter was changed. Both experiments were conducted under the same conditions using the pre-incubation method.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

S. typhimurium strains TA 98, TA 100, TA 1535 and TA 1537, and *E. coli* strain WP2 uvrA were exposed to AMPA, metabolite of glyphosate (batch A-960719, purity: 99.33 %) in the presence and absence of metabolic activation (phenobarbital and 5,6 benzoflavone-induced rat liver S9 fraction). Two independent experiments were performed according to the pre-incubation method.

Based on the results of a preliminary range-finding study, in which no cytotoxicity was observed up to 5000 µg/plate, test item concentrations for the reverse mutation assay were selected in the range of 313 – 5000 µg/plate. Solvent (water) and appropriate positive controls were included in all experiments. The bacteria strains were exposed for 48 hours at 37 °C, followed by an inspection of the bacterial background lawn and counting of the revertant colonies for each plate.

Precipitation of the test substance was not reported. In addition, there was no cytotoxicity observed in any test strain up to the highest AMPA concentration, neither in the presence nor absence of S9 mix.

There was no relevant increase in the number of his^+ and trp^+ revertants (exceeding a factor of 2 when compared to solvent controls) observed in any experiment in any strain, neither with nor without metabolic activation.

The number of revertants induced by the solvent control was within expected range for each strain, thus demonstrating an acceptable experimental performance. The positive control compounds induced a marked increase in the number of revertant colonies in all strains, demonstrating the validity of the test system and the functionality of the S9 mix.

Based on the results of the present study and under the conditions of the test, AMPA, metabolite of glyphosate is not mutagenic in the Ames pre-incubation test with and without metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: AMPA

Identification: Not specified

Description: White powder

Lot/Batch #: A-960719

Purity: 99.33 %

Stability of test compound: The test item was stable for 1 year at room temperature. The stability of the test item in solvent was not specified.

Solvent used: Sterile water

2. Control materials:

Negative control: A negative control was not employed in this study.

Solvent control: Sterile water

Solvent/final concentration: 100 µL/plate

Positive controls: Please refer to the table below.

Strain	Metabolic activation	Mutagen	Solvent	Conc. [µg/plate]
S. typhimurium strains				
TA 100	-S9	2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2)	DMSO	0.01
	+S9	2-Aminoanthracene (2-AA)	DMSO	1.0
TA 1535	-S9	Sodium azide (NaN_3)	Water	0.5
	+S9	2-Aminoanthracene (2-AA)	DMSO	2.0
TA 98	-S9	2-(2-furyl)-3-(5-nitro-2-furyl) acrylamide (AF-2)	DMSO	0.1
	+S9	2-Aminoanthracene (2-AA)	DMSO	0.5
TA 1537	-S9	9-Aminoacridine (9-AA)	Water	80.0
	+S9	2-Aminoanthracene (2-AA)	DMSO	2.0
E. coli strain(s)				
WP2 uvrA	-S9	2-(2-furyl)-3-(5-nitro-2-furyl) acrylamide (AF-2)	DMSO	0.01
	+S9	2-Aminoanthracene (2-AA)	DMSO	10.0

3. Metabolic activation:

S9 mix was purchased from [redacted] ([redacted]; Lot no. RAA-350). The homogenate was produced from the livers of male Sprague-Dawley rats. The animals were about 7 weeks old, weighing 203 - 254 g and received intraperitoneal injections of phenobarbital (30 mg/kg bw on Day 1, each 60 mg/kg bw on Days 2, 3 and 4) and 5,6 benzoflavone (80 mg/kg bw on Day 3). The S9 mix was prepared immediately before the experiment by mixing S9 fraction and co-factors.

S9 mix component	Concentration	Unit
Sodium phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADH	4	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	10	% (v/v)

4. Test organisms:

Tester strains				Bacteria batch checked for	
S. typhimurium		*E.coli*			
TA 98	✓	WP2 uvrA	✓	deep rough character (rfa)	✓
TA 100	✓	WP2 uvrA (pKM101)		ampicillin resistance (R factor plasmid)	✓
TA 1535	✓			UV-light sensitivity (absence of uvrB and uvrA genes in *S. typhimurium* and *E. coli* strains, respectively)	✓
TA 1537	✓				
TA 102					
TA 1538				Histidine and tryptophan auxotrophy (automatically via the spontaneous rate)	✓

5. Test concentrations:

3. **Preliminary cytotoxicity assay:**

Pre-incubation assay ± S9 mix:	
Concentrations:	*200, 500, 1000, 2000 and 5000 µg/plate*
Tester strains:	TA 1535, TA 1537, TA 98, TA 100 and WP2 uvrA
Replicates:	*A single plate was used per condition.*

(c) Mutation assays:

Pre-incubation assay ± S9 mix:	
Concentrations:	*313, 625, 1250, 2500 and 5000 µg/plate*
Tester strains:	TA 1535, TA 1537, TA 98, TA 100 and WP2 uvrA
Replicates:	*Triplicates in two independent experiments*

B. STUDY DESIGN AND METHODS

7. Dates of experimental work: 09 Sep – 11 Oct 1996
Finalisation date: 09 Dec 1996

8. Pre-incubation test (PIT):

0.1 mL of test solution, solvent or positive control, 0.1 mL pre-cultured bacterial suspension and 0.5 mL of S9 mix (in tests with metabolic activation) or 0.5 mL of 100 mM sodium phosphate buffer (in tests without metabolic activation) were pre-incubated with shaking for 20 minutes at 37 °C. Afterwards, 2 mL of molten soft agar (supplemented with 0.5 mM L-histidine and 0.5 mM D-biotin or 0.5 mM L-tryptophan) was added to each test tube. The contents were mixed uniformly and overlaid on a minimal glucose agar plate. Each concentration and the controls were tested in triplicates. After an incubation period of 48 h at 37 °C, bacterial background lawn was inspected and the number of bacterial colonies (his^+ or trp^+ revertants) were counted.

9. Cytotoxicity:

Cytotoxicity was investigated in a preliminary dose-range finding study. Toxicity was detected by a

- reduction in the number of revertants
- clearing or diminution of the background lawn (= reduced his^- or trp^- background growth)

and recorded for all test groups both with and without S9 mix in all experiments.

10. Statistics:

Results were judged without statistical analysis.

11. Acceptance criteria:

The test was valid if

- The culture of the tester strains, the solution of the test substance and S9 mix were free from contamination or other bacteria.
- A normal number of spontaneous revertant colonies was observed for the solvent control.
- An at least 3-fold increase above the solvent control in the mean number of revertants was observed in the positive control.

12. Evaluation criteria:

Results were judged positive without statistical analysis when the following criteria were met:

- A two-fold or greater increase above solvent control in the mean number of revertants was observed.
- This increase in the number of revertants was accompanied by a dose-response relationship.
- This increase in the number of revertants was reproducible.

Reproducibility of results was confirmed by two independent experiments.

II. RESULTS AND DISCUSSION

E. ANALYTICAL DETERMINATIONS

Analytical determinations were not performed in the study.

F. CYTOTOXICITY

In the preliminary cytotoxicity test, as well as in the main gene mutation assay, the test substance did not show any cytotoxicity in any strain up to the highest dose of 5000 µg/plate, neither in the presence, nor in the absence of metabolic activation.

G. SOLUBILITY

Precipitation of the test substance was not reported.

H. MUTATION ASSAY

A relevant increase (≥ 2-fold when compared to corresponding solvent controls) in the number of his^+ or trp^+ revertants was not observed in any experiment at any tested concentration neither in the presence nor absence of metabolic activation.

The number of revertants induced by the solvent control was within the expected range for each strain, thus demonstrating an acceptable experimental performance.

The positive control compounds induced a marked increase in the number of revertant colonies in all strains, demonstrating the validity of the test system and the functionality of the S9 mix.

Study conclusion:
According to the results of the present study, the test item is not mutagenic in the Ames pre-incubation test with and without metabolic activation under the experimental conditions of the test.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, AMPA was negative for gene mutation in bacteria (*S. typhimurium* TA 100, TA 98, TA 1535 and TA 1537 and *E. coli* WP2 uvrA) in the Ames pre-incubation test with and without metabolic activation.
The study was conducted in accordance with OECD guideline 471 and 472 (1983) and in compliance with GLP. When compared with the current OECD guideline 471 (1997), deviations of minor degree were observed. The study is considered supplementary because two tests were performed under identical conditions (using the pre-incubation method only and a plate-incorporation test was apparently not performed).

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/020
Report author	[redacted]
Report year	1993
Report title	Mutagenicity test: Ames Salmonella Test with AMPA, batch 286-JRJ-73-4
Report No	13269
Document No	145-GLY
Guidelines followed in	OECD 471 (1983), US EPA FIFRA 84-2

study	
Deviations from current test guideline (OECD 471, 1997)	The test was conducted in 4 valid strains only. Strains like *S. typhimurium* TA 102 or *E. coli* WP2 enabling the detection of cross-linking mutagens were not included. In addition, 2-aminoanthracene was used as sole positive control substance in the presence of S9 mix. Historical control data were not provided. Acceptance criteria were not defined and evaluation criteria did not consider historical control data.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

AMPA (batch: 286-JRJ-73-4, purity: 99.2 %), metabolite of glyphosate was investigated for its potential to cause gene mutation in bacteria (Ames test). *S. typhimurium* strains TA 98, TA 100, TA 1535 and TA 1537 were exposed to the test item, solvent (distilled water) and appropriate positive controls in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). Dose levels were selected based on the results of a preliminary toxicity test in strain TA 98, in which no cytotoxicity was observed up to the highest tested concentration of 5000 µg/plate.

In the main experiment, two independent experiments were performed, using the plate incorporation method (standard plate test, first experiment) and the pre-incubation method (second experiment) and test item concentrations in the range of 310 – 5000 µg/plate.

Precipitation of the test item was not reported. In both experiments, there was no cytotoxicity, evident as a reduction in the number of revertant colonies or a diminution of the bacterial background lawn observed up to the highest concentration of 5000 µg/plate, neither in the presence, nor in the absence of S9 mix.

In addition, there was no statistically significant and biologically relevant increase in the number of revertant colonies observed in any experiment for any strain at any concentration, neither in the presence nor in the absence of metabolic activation. A single statistically significant increase in the number of revertant colonies was observed for strain TA 1535 at 630 µg/plate in the absence of S9 mix, but as the increase was only of marginal magnitude and without any dose response relationship, the effect was considered to be incidental.

The number of revertant colonies induced by the negative and the positive controls were within the expected range, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

Under the experimental conditions chosen, AMPA, metabolite of glyphosate, is not mutagenic in the Ames standard plate and pre-incubation test with and without metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Aminomethyl phosphonic acid (AMPA, metabolite of glyphosate)
Identification:	AMPA
Description:	White powder
Lot/Batch number:	286-JRJ-73-4
Purity:	99.2 %

Stability of test compound: The stability of the test item at storage conditions (at room temperature in the dark) was guaranteed for at least 3 years. The stability of the test item in solvent was not specified.

Solvent (vehicle) used: Distilled water

2. Control materials:

Negative control: A negative control was not employed in this study.

Solvent (vehicle) control: Distilled water

Solvent (vehicle)/final concentration: 0.1 mL per plate.

Positive controls: Please refer to table below.

Strain	Metabolic activation	Mutagen	Conc. [µg/plate]
S. typhimurium strains			
TA 100	-S9	Sodium azide	1.0
	+S9	2-Aminoanthracene	1.25
TA 1535	-S9	Sodium azide	1.0
	+S9	2-Aminoanthracene	1.25
TA 98	-S9	2-Nitrofluorene	1.0
	+S9	2-Aminoanthracene	1.25
TA 1537	-S9	2-Nitrofluorene	1.0
	+S9	2-Aminoanthracene	1.25

3. Metabolic activation:

S9 mix was obtained from the livers of SPF Wistar rats (Mol:WIST) weighing approx. 200 g. The animals received a single intraperitoneal injection of Aroclor 1254 at a dose of 500 mg/kg bw. The livers were prepared 5 days after treatment. The S9 mix was thawed prior to each experiment and co-factors were immediately added to prepare S9-mix containing the following components:

S9 mix component	Concentration	Unit
Phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	5	% (v/v)

4. Test organisms:

Tester strains				Bacteria batch checked for	
S. typhimurium		***E.coli***			
TA 98	✓	WP2 uvrA		deep rough character (rfa)	✓
TA 100	✓	WP2 uvrA (pKM101)		ampicillin resistance (R factor plasmid)	✓
TA 1535	✓			UV-light sensitivity (absence of uvrB and uvrA genes in *S. typhimurium* and *E. coli* strains, respectively)	✓
TA 1537	✓				
TA 1538				Histidine auxotrophy (automatically via the spontaneous rate)	✓

5. Test concentrations:

(c) Preliminary cytotoxicity assay:

Plate incorporation test ± S9 mix:	
Concentrations:	*62 - 5000 µg/plate*
Tester strains:	TA98
Replicates:	*Not specified*

(d) Mutation assays:

Plate incorporation test ± S9 mix:	
Concentrations:	*310, 630, 1300, 2500 and 5000 µg/plate*
Tester strains:	TA 1535, TA 1537, TA 98 and TA 100
Replicates:	*Triplicates*
Pre-incubation test ± S9 mix:	
Concentrations:	*310, 630, 1300, 2500 and 5000 µg/plate*
Tester strains:	TA 1535, TA 1537, TA 98 and TA 100
Replicates:	*Triplicates*

B. STUDY DESIGN AND METHODS

7. **Dates of experimental work:** 20 Oct – 06 Nov 1992
   Finalisation date: 18 Feb 1993

8. **Standard plate test (plate-incorporation test, SPT):**
   An aliquot of 0.1 mL test solution, vehicle or positive control, an aliquot of 0.1 mL fresh bacterial culture and 0.5 mL S9 mix (in tests with metabolic activation only) were added to 2 mL of molten top agar (supplemented with 0.05 mM histidine and 0.05 mM biotin). After whirl mixing, the mixture was spread on a Vogel-Bonner agar plate and incubated for 48 – 72 hours at 37 °C. Each concentration and the controls were tested in triplicates. Following incubation, the bacterial background lawn was examined and the number of his^+ revertants colonies were counted.

9. **Pre-incubation test (PIT):**
   0.1 mL of test solution, vehicle or positive control, 0.1 mL bacterial suspension and 0.5 mL of S9 mix (in tests with metabolic activation only) were mixed and pre-incubated in a test tube for 30 minutes at 37 °C under gentle shaking. After pre-incubation, 2.0 mL of top agar was added, the mixture was whirl mixed and spread on a Vogel-Bonner agar plate. After an incubation period of 48 – 72 hours at 37 °C the bacterial background lawn was examined and the number of his^+ revertants colonies were counted.

10. **Cytotoxicity**
    Toxicity was detected by a
    - reduction in the number of spontaneous revertants
    - clearing or diminution of the background lawn (= reduced his^- or trp^- background

growth)
and recorded for all test groups both with and without S9 mix in all experiments.

11. Statistics

Statistical analysis of the negative control versus test data was performed using the Analysis of Variance method.

12. Acceptance criteria

Acceptance criteria were not specified in the study report.

13. Evaluation criteria

A test item was considered positive (mutagenic) in the assay if the following criteria were met:

- There was a statistically significant and dose related increase in the level of revertants on the test plates as compared to the control plates.
- The number of revertants at the dose level were the highest effect was found should be more than twice the concurrent spontaneous level.

Sporadic occurring statistically significant increases in revertants which were not dose related (i.e. occurring at the lower dose level when there was no increase at higher non-toxic doses) were considered incidental and not relevant for the evaluation.

II. RESULTS AND DISCUSSION

E. ANALYTICAL DETERMINATIONS

Analytical determinations were not performed in the study.

F. CYTOTOXICITY

In the preliminary toxicity test in strain TA 98, cytotoxicity measured as a colony count reduction was not observed at any dose level, neither in the presence nor absence of S9 mix.
In the main mutagenicity assay there was no cytotoxicity observed for any tester strain up to the highest tested concentration of 5000 µg/plate, neither with nor without S9 mix. In addition, there was no depression of the background growth observed in any tester strain at any concentration, neither in the presence nor absence of S9 mix.

G. SOLUBILITY

Precipitation was not reported in the study report.

H. MUTATION ASSAY

There was no statistically significant and biologically relevant increase in the number of his^+ revertant colonies observed in any experiment for any strain at any concentration, neither in the presence nor in the absence of S9 mix. A single statistically significant increase in the number of revertant colonies was observed for TA 1535 at 630 µg/plate in the absence of S9 mix, but as the increase was only of marginal magnitude and without any dose response relationship, the observation was considered to be incidental.
The number of revertant colonies induced by the negative and the positive controls were within the expected range, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

III. CONCLUSIONS

Based on the experimental findings, AMPA, metabolite of glyphosate was negative for gene mutation in bacteria in the Ames standard plate test and the pre-incubation test in the presence and absence of metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In this Ames test, AMPA was negative for gene mutation in bacteria (*S. typhimurium* TA 100, TA 98, TA 1535 and TA 1537) with and without metabolic activation.
The study was conducted in accordance with OECD guideline 471 (1983) and compliant with GLP. It is considered to provide supporting information, as both experiments were conducted using only 4 valid tester strains. Strains like *S. typhimurium* TA 102 or *E. coli* WP2 enabling the detection of cross-linking mutagens were not included. Further deviations from the currently valid OECD guideline 471 (1997) were of minor degree and considered to not compromise the validity of the study.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/021
Report author	[redacted]
Report year	1988
Report title	Aminomethyl Phosphonic Acid: An Evaluation of Mutagenic Potential Using *S. typhimurium* and *E. coli*
Report No	CTL/P/2206

Document No	YV2281
Guidelines followed in study	OECD 471 (1983); OECD 472 (1983)
Deviations from current test guideline (OECD 471 , 1997)	2-Aminoanthracene was used as sole positive control substance in the presence of S9 mix for all strains. Historical control data were not provided. Evaluation of cytotoxicity and precipitation were not reported, but concentrations were tested up to limit doses. No confirmation in the report of bacterial cell density at the time of treatment. Acceptance and evaluation criteria specified in the study report were not fully in accordance with those specified in OECD guideline 471 (1997).
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

S. typhimurium strains TA 98, TA 100, TA 1535, TA 1537 and TA 1538, and *E. coli* strain WP2 uvrA pKM101 were exposed to aminomethyl phosphonic acid (batch: 48F-3893, purity: > 99 %) in the presence and absence of metabolic activation (Aroclor 1254 - induced rat liver S9 fraction). For each strain, two independent experiments were conducted according to the standard plate test (plate-incorporation method) at test item concentrations in the range of 1.8 – 5000 µg/plate. Solvent (deionized water) and appropriate positive controls were included in each experiment. After 64 – 68 hours of incubation, the bacterial background lawn was inspected and the number of revertant colonies was examined.

Evaluation of precipitation and cytotoxicity was not provided in the study report. Cytotoxicity was evaluated retrospectively by comparing the presented mean numbers of revertant colonies induced by the test item to the mean number of spontaneous revertants observed in the corresponding solvent control. Cytotoxicity was observed in the first experiment for strain TA 1538 at 1000 µg/plate in the absence of S9 mix and in the second experiment for strain TA 1537 at 5000 µg/plate in the presence of S9 mix.

There was no statistically significant, reproducible increase in in the number of his^+ and trp^+ revertant colony numbers in any of the six tester strains at any dose level, neither in the presence nor absence of metabolic activation. Statistical significance in the mean number of revertant colonies was observed for all strains at single test item concentrations in the presence or absence of metabolic activation. However, none of the observations was consistent in independent experiments or showed a dose-response relationship. For strain TA 1537 in the first experiment, the increase in the mean number of revertant colonies was up to 2-fold over control conditions (200 µg/plate) in the absence of S9 mix and up to 1.9-fold over control conditions (8 and 40 µg/plate) in the presence of S9 mix. In both cases, the responses were only of limited dose-response relationship and of limited statistical significance ($p > 0.01$). Besides, the effects were not reproducible in two further experiments with this strain. Considering all available data of the present study, there was no consistent, statistically significant or biologically relevant increase in the mean number of his^+ or trp^+ revertant colonies observed for any tester strain up to the highest concentration of 5000 µg/plate.

The positive control compounds showed the expected results of markedly increased numbers of revertant colonies, indicating the functionality of the S9 mix and demonstrating the validity of the test system.

Based on the results and under the experimental conditions of the present study, there is no indication for mutagenicity in the Ames standard plate test in the presence and absence of metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: Aminomethyl phosphonic acid

Identification: Y06384/001/001

Description: White solid

Lot/Batch #: 48F-3893

Purity: > 99 %

Stability of test compound: Not specified.

Solvent (vehicle) used: Sterile deionised water

2. Control materials:

Negative control: Not specified.

Solvent (vehicle) control: Sterile deionised water

Solvent (vehicle)/ final concentration: 100 µL per plate

Positive controls: Please refer to the table below.

Strain	Metabolic activation	Mutagen	Solvent	Conc. [µg/plate]
S. typhimurium strains				
TA 100	-S9	N-Methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	1.0, 2.0 and 5.0
	+S9	2-Aminoanthracene (2AA)	DMSO	0.2, 0.5 and 1.0
TA 1535	-S9	N-Methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	1.0, 2.0 and 5.0
	+S9	2-Aminoanthracene (2AA)	DMSO	0.5, 1.0 and 2.0
TA 98	-S9	Daunomycin Hydrochloride (DR)	DMSO	0.2, 0.5 and 1.0
	+S9	2-Aminoanthracene (2AA)	DMSO	0.2, 0.5 and 1.0
TA 1537	-S9	Acridine Mutagen ICR191	DMSO	0.5, 1.0 and 2.0
	+S9	2-Aminoanthracene (2AA)	DMSO	0.5, 1.0 and 2.0
TA 1538	-S9	4-Nitro-o-phenylenediamine (4NOPD)	DMSO	1.0, 2.0 and 5.0
	+S9	2-Aminoanthracene (2AA)	DMSO	0.2, 0.5 and 1.0
E. coli strains				
WP2 uvrA	-S9	N-Methyl-N'-nitro-N-nitrosoguanidine (MNNG)	DMSO	0.5, 1.0 and 2.0
	+S9	2-Aminoanthracene (2AA)	DMSO	1.0, 2.0 and 5.0

3. Metabolic activation:

S9 mix was obtained from the livers of male Sprague-Dawley rats, that received a single dose of 500 mg/kg bw Aroclor 1254 by intraperitoneal injection. The treated animals were kept on a normal diet for three days, starved of food but not water on the fourth day and the livers were prepared on the fifth day. A 25 % (w/v) homogenate fraction was prepared and aliquots were frozen. The S9 mix was thawed prior to each experiment and co-factor was immediately added to prepare S9 mix containing the following components:

S9 mix component	Concentration	Unit
Na_2HPO_4 buffer	150	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP, Na salt	4	mM
$MgCl_2$	8	mM
S9	25	% (v/v)

4. Test organisms:

Tester strains				Bacteria batch checked for	
S. typhimurium		***E.coli***			
TA 98	✓	WP2 uvrA pKM101	✓	deep rough character (rfa)	✓
TA 100	✓	WP2 P		ampicillin resistance (R factor plasmid)	✓
TA 1535	✓			UV-light sensitivity (absence of uvrB and uvrA genes in *S. typhimurium* and *E. coli* strains, respectively)	✓
TA 1537	✓				
TA 102					
TA 1538	✓			Histidine and tryptophan auxotrophy (automatically via the spontaneous rate)	✓

5. Test concentrations:

Plate incorporation test ± S9 mix:	
Concentrations:	*1.6, 8.0, 40.0, 200, 1000 and 5000 µg/plate*
Tester strains:	TA 1535, TA 1537, TA 1538, TA 98, TA 100 and WP2 uvrA
Replicates:	*Triplicates*

B. STUDY DESIGN AND METHODS

8. Dates of experimental work: 10 – 23 May 1988
Finalisation date: 21 Sep 1988

9. Standard plate test (plate-incorporation test, SPT):

An aliquot of 0.1 mL test solution or solvent/ positive control, an aliquot of 0.1 mL bacterial overnight culture and 0.5 mL S9 mix (in tests with metabolic activation) or 0.5 mL of sucrose-tris-EDTA buffer (in tests without metabolic activation) were added to 2 mL of molten top agar (supplemented with 0.5 mM histidine/ 0.5 mM biotin stock solution (10 mL solution : 100 mL agar) or 10 mL 0.5 mM tryptophan solution per 100 mL agar). The resulting mixture was poured rapidly onto Vogel Bonner agar plates. The plates were allowed to gel and incubated inverted at 37 °C for 64 - 68 h in the dark. Afterwards, the plates were checked for microbial contamination, the background bacterial lawn was examined and the number of the bacterial colonies (his^+ or trp^+ revertants) was counted.
All strains were tested in two independent experiments and a third experiment was performed for tester strain TA1537. In each experiment, all test item concentrations and the controls were tested in triplicates.

10. Cytotoxicity

Evaluation of cytotoxicity was not further specified in the study report. Thus, retrospectively, cytotoxicity was evaluated by comparing the presented mean numbers of revertant colonies induced by the test item to the mean number of spontaneous revertants observed in the corresponding solvent control. Cytotoxicity was considered evident when the mean number of revertant colonies induced by the test item concentration was ≤ 0.5 fold of the mean number of spontaneous revertant colonies induced by the solvent control.

11. Statistics

An assessment of statistical significance was carried out using a one-tailed Student's t-test. The corresponding probability for each dose level was derived by computer using the appropriate degrees of freedom. Values of $p < 0.01$ were treated as significant with values of $0.01 \leq p < 0.05$ being indicative

of a possible effect.

12. Acceptance criteria

The test was valid if;

- The concurrent solvent control data were acceptable.
- The positive control data showed unequivocal positive responses.
- At least the lowest test item dose showed no evidence of toxicity, and at least three test item doses showed no significant overt toxicity.

Failure of one or more tester strain / S9 combinations did not invalidate the data for the remainder of a concurrent experiment.

13. Evaluation criteria

A positive response in an individual experiment was achieved when one or both of the following criteria were met:

- A statistically significant dose-related increase in the mean number of revertant colonies was obtained.
- A two-fold or greater increase of statistical significance in the mean number of revertant colonies was observed at one or more concentrations.

For a positive response in an individual experiment to be considered indicative of an unequivocal positive, i.e. mutagenic, result for that strain / S9 combination, then the observed effects must be consistently reproducible.

A negative response in an individual experiment was achieved when

- There was no statistically significant dose-related increase in the mean number of revertant colonies per plate observed for the test substance.
- In the absence of any such dose response, no increase in colony numbers was observed at any test concentration, which exceeded 2x the concurrent solvent control.

II. RESULTS AND DISCUSSION

E. ANALYTICAL DETERMINATIONS

Analytical determinations were not performed in the study.

F. CYTOTOXICITY

Cytotoxicity, evident as a reduced number of revertant colonies was observed in the first experiment for strain TA 1538 at 1000 µg/plate in the absence of S9 mix and in the second experiment for strain TA 1537 at 5000 µg/plate in the presence of S9 mix.

G. SOLUBILITY

There was no precipitation of the test substance reported.

H. MUTATION ASSAY

Although a statistically significant increase in the mean number of revertant colonies was observed in the first experiment in strains TA 1535, TA 1537 and WP2 uvrA in the absence of S9 mix and in strains TA 1535, TA 1537, TA 1538, TA 98 and WP2 uvrA in the presence of S9 mix, as well as in the second experiment in strain TA1535 in the absence of S9 mix and in strains TA 100 and WP2 uvrA in the presence of S9 mix, none of these observations showed a dose-response relationship. In addition, the observations were not reproducible in independent experiments. For strain TA 1537 in the first experiment, the increase in the mean number of revertant colonies was up to 2-fold over control conditions (200 µg/plate) in the absence of S9 mix and up to 1.9-fold over control conditions (8 and 40 µg/plate) in the presence of S9 mix. In both cases, the responses were only of limited dose-response relationship and of limited statistical significance ($p > 0.01$). Therefore, for strain TA 1537 a third experiment was conducted under the same experimental conditions. In the latter two experiments, no significant increases in colony numbers were observed for TA 1537 either with or without S9 mix. Considering all available data of the present study, there was no consistent, statistically significant or biologically relevant increase in the mean number of his^+ or trp^+ revertant colonies observed for any tester strain up to the highest concentration of 5000 µg/plate.
The positive control compounds showed the expected results of markedly increased numbers of revertant colonies, indicating the functionality of the S9 mix and demonstrating the validity of the test system.

III. CONCLUSIONS

In conclusion, under the experimental conditions reported, the test item is not mutagenic in the Ames test (standard plate test / plate-incorporation method) with and without metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Although statistical significance in the mean number of revertant colonies was observed for all strains at single test item concentrations in the presence or absence of metabolic activation, none of the observations was consistent in independent experiments or showed a dose-response relationship. For strain TA 1537 in the first experiment, the increase in the mean number of revertant colonies was up to 2-fold over control conditions (200 µg/plate) in the absence of S9 mix and up to 1.9-fold over control

conditions (8 and 40 µg/plate) in the presence of S9 mix. In both cases, the responses were only of limited dose-response relationship and of limited statistical significance ($p > 0.01$). Besides, the effects were not reproducible in two further experiments with this strain. Considering all available data of the present study, there was no consistent, statistically significant or biologically relevant increase in the mean number of his^+ or trp^+ revertant colonies observed for any tester strain up to the highest concentration of 5000 µg/plate. Thus, the test item was considered negative for gene mutation in bacteria (*S. typhimurium* TA 100, TA 98, TA 1535, TA 1537 and TA1538 and *E. coli* WP2 uvrA pKM101) with and without metabolic activation.
The study was performed in compliance with GLP and according to OECD guideline 471 (1983). There were only minor deviations when compared to the currently valid OECD guideline 471 (1997), which were considered to not compromise the outcome and the validity of the study. The study is therefore considered valid and acceptable.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.8.1/022
Report author	[redacted]
Report year	1980
Report title	CP50435: Microbial Mutagenicity Study
Report No	ET-80-402
Document No	NA
Guidelines followed in study	No guideline followed, the study was conducted similarly to OECD 471 (1983)
GLP	No, not conducted under GLP/ Officially recognised testing facilities. When the study was conducted, GLP was not compulsory.
Previous evaluation	Not accepted in RAR (2015)
Short description of study design and observations:	Aminomethylphosphonic acid (CP50435, batch: not reported, purity: 99 %), metabolite of glyphosate was investigated for gene mutation in bacteria in an Ames test. *S. typhimurium* strains TA 98, TA 100, TA 1535, TA1537 and TA 1538, and *E. coli* strain WP2 hcr were exposed to the test item, solvent (water) and appropriate positive controls in the presence and absence of metabolic activation (Aroclor-induced rat liver S9 fraction). A single experiment (plate-incorporation method) was performed, with duplicate cultures, using test item concentrations in the range of 10 – 5000 µg/plate. After incubation at 37 °C for two days, the number of bacterial colonies (his^+ or trp^+ revertants) were counted.
Short description of results:	Evaluation of precipitation and cytotoxicity were not included in the study report. However, when comparing the number of revertant colonies of test item treated plates to vehicle controls, there was no evidence for cytotoxicity. The test item did not induce a statistically significant increase in the number of his^+ or trp^+ revertants in any of the tester strains at any concentration when compared to solvent controls, neither in the presence nor in the absence of metabolic activation. The positive controls markedly increased the number of revertant colonies in all strains, demonstrating the functionality of the S9 fraction and the sensitivity of the test system. Based on the experimental results and under the conditions of the test, aminomethylphosphonic acid, metabolite of glyphosate, is negative for gene mutation in bacteria (Ames test) with and without metabolic activation.

Reasons for why the study is not considered relevant/reliable or not considered as key study:	The study was considered not acceptable due to a number of guideline deviations when compared to OECD guideline 471 (1997). Only a single experiment was performed without giving a justification for the missing confirmatory experiment. Instead of *E. coli* strain WP2 uvrA, strain WP2 hcr was used. In addition, 2-aminoanthracene was used as sole positive control substance in the presence of S9 mix. Historical control data were not provided and evaluation of cytotoxicity and precipitation were not reported. Acceptance and evaluation criteria were not specified in the study report. The study is therefore considered not valid.
Reasons why the study report is not available for submission	
Category study in AIR5 dossier (L-docs)	Category 3b

1. Information on the study

Data point	CA 5.8.1/023
Report author	[redacted]
Report year	1993
Report title	Mutagenicity test: In vitro Mammalian Cell Gene Mutation Test performed with Mouse Lymphoma Cells (L5178Y). Test compound: AMPA, batch 286-JRJ-73-4.
Report No	13270
Document No	NA
Guidelines followed in study	OECD 476 (1983), US CFR part 700 (F) § 798.5300 (1987)
Deviations from current test guideline (OECD 490, 2016)	The newly introduced cytotoxicity parameters RTG (relative total growth), SG (suspension growth) and RSG (relative suspension growth) in OECD TG 490 (2016) could not be re-calculated, since no data on suspension growth were generated. In the current study, cytotoxicity was evaluated based on cloning efficiency after treatment (CE_1, survival) and after selection (CE_2, viability), in accordance with the previous guideline version. Although the growth rates of the cultures were monitored, the data were not provided within the study report. Further, the number of cells treated was below 6 x 10^6 cells, the number of cells recommended in OECD 490 (2016). In several instances, vehicle control cultures exceeded spontaneous levels recommended by OECD guideline 490 (2016). pH and osmolality changes were not assessed. Acceptance criteria specified in the current guideline were not applied and evaluation criteria were based solely on statistics but not on GEF. Although GEF was applied retrospectively, no linear trend was assessed. It was indicated in the report that statistical analysis were conducted, however, they were not clearly reported. In addition, no historical control data were provided for the negative and the positive controls.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

AMPA (batch: 286-JRJ-73-4, purity: 99.2 %), metabolite of glyphosate, was tested in a Mouse Lymphoma assay for its ability to induce forward mutations in mammalian cells *in vitro*. In two independent experiments, duplicate cultures of Mouse Lymphoma L5178Y $TK^{+/-}$ cells were exposed to the test item, medium or appropriate positive controls (75 and 100 µg/mL ethylnitrosourea (ENU) without S9 mix and 5 and 10 µg/mL dimethylbenzanthracene (DMBA) with S9 mix). The assay was conducted in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction).
After 3 hours of exposure with S9 mix or 4 hours of exposure without S9 mix, the cells were incubated for 2 - 3 days to allow expression of the mutant phenotype. The expression period was followed by a selection period, in which the cells were cultivated in selection medium containing trifluorothymidine (TFT) for a period of 10 days. Cell survival and cell viability were assessed as cloning efficiency 1 and cloning efficiency 2 at the end of the exposure period and after the expression period, respectively.
Precipitation of the test item in the medium was not reported and there was no cytotoxicity observed up to the highest tested concentration, neither in the presence nor in the absence of S9 mix. Upon treatment with AMPA there was no statistically significant increase in the number of mutant colonies observed in any of the experiments at any concentration, neither in the presence nor in the absence of S9 mix. Mutant frequencies of the medium control cultures were in the expected range. The positive controls ethylnitrosourea and dimethylbenzanthracene markedly increased the mutation frequency, thus demonstrating functionality of the metabolic activation system and the sensitivity of the test.
Based on the results of the present study, AMPA, metabolite of glyphosate, did not induce mutant frequencies in L5178Y $TK^{+/-}$ cells in the presence or absence of S9-mix and is therefore considered non-mutagenic for mammalian cells *in vitro*.

I. MATERIALS AND METHODS

A: Materials

1. Test material:

	Aminomethyl phosphonic acid (AMPA, metabolite of glyphosate)
Identification:	AMPA
Description:	White powder
Lot/Batch number:	286-JRJ-73-4
Purity:	99.2 %
Stability of test compound:	The stability of the test item at storage conditions (at room temperature in the dark) was guaranteed for at least 3 years. The stability of the test item in solvent was not specified.
Solvent (vehicle) used:	Culture medium

2. Control material:

Negative control:	Untreated cell cultures which were cultivated in cultivation medium only were included in each experiment.
Solvent (vehicle) control:	As culture medium was used as solvent for the test item, the solvent control represents actually the negative control.
Positive control:	- S9 mix: Ethylnitrosourea (ENU), 75 and 150 µg/mL + S9 mix N-nitrosodimethylamine (DMBA), 5 and 10 µg/mL

3. Metabolic activation:

S9 mix was obtained from the livers of Wistar rats weighing approximately 200 g. The rats received a single intraperitoneal injection of Aroclor-1254 at a dose of 500 mg/kg bw. The animals were sacrificed for preparation of liver homogenates 5 days after treatment following a 16 hour period of fasting. The

S9 mix was prepared immediately before the experiment by mixing S9 fraction and co-factors.

S9 mix component	Concentration	Unit
Hepes buffer, 1M (pH 7.2)	20	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	3	mM
NADP	4	mM
$MgCl_2$	5	mM
S9	12	% (v/v)

4. Test organism:

L5178Y $TK^{+/-}$ mouse lymphoma cells were used. Stocks were maintained in liquid nitrogen and thawed immediately before use. Each batch used for mutagenicity testing was checked for general morphology, growth characteristics and absence of mycoplasma.

5. Cell culture media:

Cultivation medium: RPMI 1640 medium, supplemented with 10 % horse serum, 200 µg/mL sodium pyruvate and 50 µg/mL gentamicin

Pre-treatment medium A ("THMG medium"): Cultivation medium, supplemented with 9 µg/mL hypoxanthine, 15 µg/mL methotrexate and 22.5 µg/mL glycine

Pre-treatment medium B / treatment medium ("THG medium"): Cultivation medium supplemented with 50 % conditioned medium, 9 µg/mL hypoxanthine and 22.5 µg/mL glycine

Selection medium: Cultivation medium, supplemented with 10 % horse serum and 4 µg/mL trifluorothymidine (TFT)

Incubation: *At 37 °C and 5 % CO_2*

6. Locus examined: Thymidine kinase (TK)

7. Test concentrations and number of replicates:

The dose-range was selected on the basis of a preliminary toxicity test (data not provided in study report) in which the cell-growth was measured for a period of 2-3 days after exposure. If possible the maximum dose was chosen so that the survival (cloning efficiency) was approximately 20 % and so that the cells grew at a normal rate before the end of the 3 day period.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 14 Dec 1992 – 21 Jan 1993

Finalisation date: 18 Feb 1993

2. Mutation assay:

Pre-treatment of cells:

Thawed cells were maintained at a density of 2 x 10^5 - 1.5 x 10^6 in sterile NUNC plastic flasks and incubated at 37 °C and 5 % CO_2. Prior to treatment, spontaneous TK deficient mutants ($TK^{-/+}$ cells) were eliminated from the stock cultures by incubating the cells for 1 - 2 days in THMG medium (pre-treatment medium A), followed by a recovery period of 1 - 3 days in THG medium (pre-treatment medium B).

Treatment:

Two independent experiments using duplicate cultures per condition were performed in the presence and absence of metabolic activation.

For treatment of cells in the absence of S9 mix, cell suspensions of 15 mL containing 3 x 10^5 cells/mL were mixed with 1 mL test item solution, resulting in final concentrations in the range of 0.31 – 5.0 mg/mL (first experiment) and 0.63 – 5.0 mg/mL (second experiment). Afterwards the cultures were incubated for 4 hours at 37 °C under gentle shaking.

For treatment of cells in the presence of S9 mix, cell suspensions of 2 mL containing 2.25 x 10^6 cells were mixed with 0.5 mL S9 mix and 0.5 mL of test item solutions, resulting in final concentrations in the range of 0.31 – 5.0 mg/mL (first experiment) and 0.63 – 5.0 mg/mL (second experiment). The cultures were incubated for 3 hours at 37 °C under gentle shaking.

At the end of the exposure period, the cells were centrifuged, re-suspended in 15 mL fresh medium and a small sample of cells from each culture was diluted and seeded in a microtiter plate at a density of 2 cells/well for determination of relative cell survival (cloning efficiency 1).

Expression period:

After the exposure period, the cells were incubated for a 2 - 3 days expression period, in which each culture was counted daily, diluted to 3 x 10^5 cells/mL and the growth rate was recorded. After the expression period, each culture was divided. One aliquot of each culture was plated to determine the cell viability (cloning efficiency 2) of the cultures, the other one was used for the selection of mutants.

Selection period:
For the selection of mutants, two microtiter plates were prepared from each post-expression culture, seeding 2000 cells per well in medium supplemented with 4 µg/mL trifluorothymidine (TFT). After an incubation period of 10 days, the number of cell clones was counted. The clones were differentiated into large clones and small dense clones. Small colonies were considered to be associated with clastogenic effects, large colonies were considered to be associated with gene mutation effects.

3. Cytotoxicity:

Cloning efficiency (CE_1 survival)
At the end of the exposure period, a sample of each cell culture was collected to assess cell survival. A full 96-well microtiter plate was seeded at a density of 2 cells/well for each culture. After 10 days of incubation, the number of colonies was counted.

CE_2 (viability)
After the expression period, 2 - 3 days after end of exposure, a sample of each cell culture was collected to assess cell viability. For each culture, a full 96-well microtiter plate was seeded at a density of 2 cells/well. After 10 days of incubation, the number of colonies was counted.

4. Evaluation:

Cytotoxicity (cloning efficiency CE)
The number of colonies divided by the number of cells plated was calculated for each sample. The absolute cloning efficiency was determined for each test group, as well as the relative cloning efficiency in comparison to the solvent control group.
CE_1 (survival)
The cytotoxicity of the test substance after the exposure period was determined for each test group and is indicated as absolute and relative cloning efficiency (CE_1 and RCE_1, respectively).

CE_2 (viability)
The cytotoxicity of the test substance at the end of the expression period was determined for each test group and is given as absolute and relative cloning efficiency (CE_2 and RCE_2, respectively).
The cloning efficiency (CE, %) was calculated for each test group as follows:

$$CE_x = -\frac{1}{2}\ln\frac{\text{Number of empty wells}}{\text{Number of wells seeded}}$$

$$RCE_x = \frac{CE_x \text{ of the test group}}{CE_x \text{ of the negative or vehicle control}} \times 100$$

Mutant frequency (MF)
The number of empty wells and the number of wells containing colonies were scored and reported. The colonies are classified into large colonies (indication of gene mutation) and small colonies (indication of chromosome breakage).

Uncorrected mutant frequency:
The uncorrected mutant frequency per 10^6 cells (MF_{uncorr}) was calculated for each test group as follows:

$$MF_{uncorr.} = -\frac{1}{2000}\ln\frac{\text{Number of empty wells}}{\text{Number of wells seeded}}$$

Corrected mutant frequency
The corrected mutation frequency (MF_{corr}) was calculated regarding the values of CE_2:

$$MF_{corr.} = \frac{MF_{uncorr.}}{CE_2} \times 100$$

Determination of borderline mutant frequency based on GEF
The GEF (global evaluation factor) method requires that the MF exceeds a value based on the global distribution of the background MF of the test method. This value is defined as the mean of the negative/vehicle MF distribution plus one standard deviation.
Based on a large data base (n = 493 experiments) from six laboratories a GEF of 126 mutant colonies per 10^6 cells [mean $MF_{corr} = 99 \times 10^{-6}$ colonies; standard deviation = 27×10^{-6} colonies] was calculated for the microwell method. To be judged positive, the mutation frequency has to exceed a threshold of 126 colonies per 10^6 cells (GEF) above the concurrent negative/vehicle control value. The borderline mutant frequency was calculated for each experiment separately as follows:
Borderline MF = $MF_{vehicle\ control\ corr}$ + GEF (126×10^{-6}). The borderline MF was not evaluated as part of the present study, but was determined retrospectively for this evaluation.

5. Statistics:
Statistical analysis was conducted using the Analysis of Variance method on the corresponding test and control cultures.

6. Acceptance criteria:
Acceptance criteria were not defined in the study report.

7. Evaluation criteria:
A substance was considered to be mutagenic if the following criteria were met:

- There was a statistically significant and reproducible increase in the mutation frequency as compared to the negative control cultures.
- A dose-response was evident.
- The mutation frequency at the dose level where the highest effect was found was more than twice the concurrent spontaneous mutant frequency.

Sporadic occurring statistically significant increases in revertants which were not dose related (i.e. occurring at the lower dose level when there was no increase at higher non-toxic doses) were considered incidental and not relevant for the evaluation.

II. RESULTS AND DISCUSSION

1. ANALYTICAL DETERMINATIONS
Analytical determinations were not performed in the present study.

2. CYTOTOXICITY
There was no significant toxicity observed upon treatment with AMPA up to the highest tested concentration of 5.0 mg/mL.

ENU: Ethylnitrosourea, DMBA: Dimethylbenzanthracene

3. SOLUBILITY

Precipitation of the test item was not reported.

4. MUTANT FREQUENCY

There was no statistically significant increase in mutation frequency observed upon treatment with AMPA in both experiments at any of the tested concentrations, neither in the presence, nor in the absence of metabolic activation. Mutant frequencies of the medium control cultures were in the expected range. The positive controls ethylnitrosourea and dimethylbenzanthracene markedly increased the mutation frequency, thus demonstrating functionality of the metabolic activation system and the sensitivity of the test.

III. CONCLUSIONS

Based on the experimental findings, AMPA, metabolite of glyphosate, did not induce mutant frequencies in L5178Y $TK^{+/-}$ cells in the presence or absence of S9-mix. Under the conditions of the test, the test item is negative for mutagenicity in mammalian cells *in vitro*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, AMPA was negative for mutagenicity in L5178Y $TK^{+/-}$ cells with and without metabolic activation.
The study was conducted according to OECD guideline 476 (1983) and in compliance with GLP. When compared to the currently valid OECD test guideline 490 (2016), there were a number of deviations of minor degree. Cytotoxicity was evaluated based on cloning efficiencies, in accordance with the previous guideline version. Mutant frequency and toxicity data given in the study report included data from 10^4 cells. For this evaluation, data were calculated retrospectively for 10^6 cells. In addition, the borderline mutant frequency based on GEF was determined retrospectively. The deviations were considered to not compromise the validity of the study. Therefore, the study was considered valid.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/024
Report author	[redacted]
Report year	2002
Report title	Measurement of unscheduled DNA synthesis (UDS) in rat hepatocytes using an *in vitro* procedure with AMPA (Aminomethylphosphonic acid)
Report No	IPL-R 020625
Document No	NA
Guidelines followed in study	OECD 482 (1986)
Deviations from current test guideline	Not applicable. OECD 482 was deleted in 2014. When compared to the previous OECD 482 (1986), no deviations were observed.
Previous evaluation	Yes, accepted in the RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Supportive

Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary
Executive summary

AMPA, metabolite of glyphosate (batch: A015478701; purity: 99.9 %) was investigated for induction of unscheduled DNA synthesis (UDS) in primary rat hepatocytes *in vitro*. Two independent experiments were performed. Hepatocytes were isolated from the livers of young male Fischer rats and exposed to test item concentrations in the range of 0.625 – 10 mM in medium supplemented with ^{3}H-thymidine. Solvent (medium) and positive controls (2-acetamidofluorene, 6.25 µM) were included in each experiment. After 17 – 20 hours of incubation at 37 °C, slides were prepared for autoradiography. In parallel, cell viability was assessed by MTT assay in separate cultures. A total of 150 cells per condition were scored for nuclear and cytoplasmatic grains and the mean number of net nuclear grains (NNG) per cell was determined to evaluate unscheduled DNA synthesis for each condition. In addition, the percentage of cells in repair and the percentage of cells in S-phase were determined.
Precipitation of AMPA in culture medium was not reported. In addition, there were no changes on osmolality. At 10 mM there was a slight change in pH value with 6.70 vs. 7.26 when compared with the solvent control. Cytotoxicity was observed in the first experiment at 10 mM and in the second experiment at 5 and 10 mM, respectively.
In both experiments, there was no statistically significant or dose-related increase in the mean number of net nuclear grain counts up to the highest tested concentration and no statistically significant increase in the percentage of cells in repair when compared with solvent controls at any tested concentration. Moreover, the frequency of cells in S-phase was low for all conditions.
Values obtained for the solvent and the positive control were within the range of the laboratories historical control data, demonstrating the validity and the sensitivity of the test. Based on the experimental findings and under the conditions of the test, AMPA, metabolite of glyphosate did not induce unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: Aminomethylphosphonic acid (AMPA)

Identification:	020404
Description:	White crystalline powder
Lot/Batch number:	A015478701
Purity:	99.9 %
Stability of test compound:	The stability of the test item at storage conditions or in solvent were not specified.

1. **Control material:**

Negative control:	The negative control is actually the solvent control.
Solvent (vehicle) control:	Culture Medium (William's E medium)
Positive controls:	2-Acetamidofluorene, 6.25 µM in DMSO

3. Hepatocyte isolation:
Primary rat hepatocytes were isolated by *in situ* collagenase perfusion from the livers of young male Fischer rats. As two independent experiments were performed, one rat liver perfusion was used for each experiment. The animals were anesthetised with pentobarbital and a V-shaped incision was made in the abdominal wall of the animals. The liver was perfused via the portal vein at 37 °C with Hepes buffer for 5 minutes, followed by 5 minutes perfusion with collagenase buffer consisting of Hepes buffer with 4 mM $CaCl^{2+}$ and 0.025 % collagenase. Finally, the perfused liver was dissected and the isolated hepatocytes were washed in a centrifugation step. Cell viability was determined using the trypan blue

technique.

4. Cell culture:

Cell culture establishment:	Freshly isolated hepatocytes were seeded in plating medium at a density of 4.5 x 10^5 cells on coverslips in conventional 6-well plates. The cells were incubated for approx. 90 minutes and allowed to attach.
Plating medium:	William's medium E
Treatment medium:	*William's medium E, supplemented with 10 µCi/mL tritiated thymidine*
Incubation:	*At 37 °C in an atmosphere of 5 % CO_2*

5. Test concentrations:

Experiment	Concentrations	Replicates
First experiment:	0.625, 1.25, 2.5, 5 and 10 mM	Triplicates
Second experiment:	0.625, 1.25, 2.5, 5 and 10 mM	Triplicates

B. STUDY DESIGN AND METHODS

(a) Dates of experimental work: 29 Apr – 02 Jul 2002
Finalisation date: 09 Oct 2002

(b) Cytotoxicity:
Cytotoxicity was determined using the MTT assay. 4.5 x 10^5 cells/well were seeded in two separate wells of a conventional 6-well plate. The cells were exposed to the test item, solvent (medium) or positive control (6.25 µM 2-acetamidofluorene) under conditions which were identical to those used for determination of unscheduled DNA synthesis. Test item concentrations of 0.625 – 10 mM were used. After 17 – 20 hours of incubation at 37 °C, the medium was removed and replaced by 2 mL medium containing 0.5 mg/mL MTT, followed by incubation for 2 - 3 hours. Thereafter, the cells were washed with phosphate buffered saline (PBS). The insoluble formozan was solubilised using HCl : isopropoanol (1 : 23) and the absorbance was read at 550 nm for each concentration.

(c) Unscheduled DNA synthesis:

Cell treatment:
After cell culture establishment, the medium was aspirated from the cells, the hepatocytes were washed with culture medium and finally exposed to the test item, solvent (medium) or positive control (6.25 µM 2-acetamidofluorene) in ^{3}H-thymidine-enriched medium. Test item concentrations in the range of 0.625 – 10 mM were used. After 17 – 20 hours of incubation at 37 °C, the cells were prepared for autoradiography.

Cell harvest and slide preparation:
After treatment, the slides were coated in Kodak NTB-2 liquid emulsion. After gelling, the slides

were incubated in a light-protected box and kept in the refrigerator for 14 days. Finally, the cells were stained with Harris hemalum, dehydrated in ethanol, cleared in xylene and mounted with coverslips for microscopic examination.

Evaluation:
To assess unscheduled DNA synthesis in hepatocytes, grain counting was performed using an image analysis system. 150 cells per condition (3 slides with 50 cells/slide) were scored for nuclear and cytoplasmic grain counts. Only cells with normal morphology were scored. Isolated nuclei with no surrounding cytoplasm, cells with unusual staining artefacts and heavily labelled cells in S-phase were not scored. Net nuclear grains per cell were determined by subtracting the number of cytoplasmatic grain counts from the number of nuclear grain counts.

4. Statistics:
Performance of statistical analysis was not specified in the study report.

5. Acceptance criteria:
The assay was considered valid if the following criteria were met:

- The negative control slides had a group mean net nuclear grain (NNG) value which was in the laboratories historical control range.
- The positive control had a group mean NNG value of not less than 5 NNG counts with 50 % or more cells having NNG counts of 5 or more and the values were statistically significant relative to the solvent control.

6. Evaluation criteria:
The test item was considered positive for unscheduled DNA synthesis (UDS) if the following criteria were met:

- At any concentration tested, group mean net nuclear grain (NNG) values were > 0 and 20 % or more of the cells responded (NNG ≥ 5).
- An increase was seen in both NNG and the percentage of cells in repair.
- A dose related increase was seen in both NNG and the percentage of cells in repair.
- Any induction of UDS was reproduced in an independent experiment.

If a test item failed to induce UDS at any dose in either experiment, it was considered clearly negative in this system.

H. RESULTS AND DISCUSSION

5. ANALYTICAL DETERMINATIONS
Analytical determinations were not performed in the study.

6. CYTOTOXICITY
Cytotoxicity was observed in the first experiment at 10 mM (84.42 % of control) and in the second experiment at 5 and 10 mM (85.9 and 81.80 % of control), respectively.
Osmolality measurements revealed no changes upon addition of AMPA to the culture medium. There was a slight decrease of the pH at 10 mM with 6.70 vs. 7.26 in the solvent control; however, the value was within the biologically acceptable range of pH (6.5 – 8). Based on these findings, 10 mM was chosen as highest concentration for the unscheduled DNA synthesis assay.

7. SOLUBILITY
Precipitation of the test item in culture medium was not reported.

8. UNSCHEDULED DNA SYNTHESIS
In two experiments, AMPA did not induce a statistically significant or dose-related increase in the mean number of net nuclear grain counts when compared to solvent controls up to the highest tested concentration

of 10 mM. In addition, there was no statistically significant increase in the percentage of cells in repair when compared with solvent controls at any tested concentration. Moreover, the frequency of cells in S-phase was low for all conditions.
Values obtained for the solvent and the positive control were within the range of the laboratories historical control data, demonstrating the validity and the sensitivity of the test.

III. CONCLUSIONS

Under the conditions of the test, AMPA, metabolite of glyphosate did not induce unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, AMPA was negative for unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.
The study was performed under GLP conditions and in accordance with OECD guideline 482 (1986), which was deleted in 2014. As the Unscheduled DNA Synthesis (UDS) assay is no longer a standard method described by current guidelines, the study was considered to provide supporting information.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/025
Report author	[redacted]
Report year	1991
Report title	Evaluation of the potential of AMPA to induce unscheduled DNA synthesis in the *in vitro* hepatocyte DNA repair assay using the male F-344 rat.
Report No	SR-91-234
Document No	Not reported
Guidelines followed in study	Similar to OECD 482 (1986)
Deviations from current test guideline	Not applicable. OECD 482 was deleted in 2014. There were no deviations when compared to the previous OECD 482 (1986).
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

AMPA, metabolite of glyphosate (batch: HET-9001-1463-T; purity: 94.38 %) was tested for induction of DNA repair (unscheduled DNA synthesis, UDS) in primary rat hepatocytes *in vitro*. Two independent experiments were performed. Hepatocytes were isolated from the livers of adult male F344 rats and the cells were exposed to test item concentrations in the range of 5 to 5000 µg/mL in medium supplemented with radiolabeled tritiated thymidine (^{3}H-TdR). In the first experiment, 8 concentration steps were used whereas 10 concentration steps were used in the second experiment. Solvent (medium) and positive controls (3 µg/mL 2-acetylaminofluorene) were included in each experiment. After 19 hours of incubation at 37 °C, the cells were visually inspected for cytotoxicity, processed for slide preparation and 90 cells per condition (3 per slide) were evaluated for UDS. UDS was quantified by determining the net increase in nuclear grain counts and the number of cells in repair.
Precipitation of the test item in solvent was not observed. Cytotoxicity was noted at 5000 µg/mL in the first experiment and at 3800 and 5000 µg/mL in the second experiment.
In both experiments, AMPA did not induce significant increases in the mean number of net nuclear grain counts in rat hepatocytes when compared to the solvent control at any of the tested concentrations. In addition, the percentage of cells in repair was ≤ 6 %. Values obtained for the solvent and the positive control were in the expected range, demonstrating the validity and the sensitivity of the test system.
Under the conditions of the test and based on the results of the present study, AMPA, metabolite of glyphosate, did not induce unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: AMPA

Identification:	Not specified
Description:	White solid
Lot/Batch number:	HET-9001-1463-T
Purity:	94.38 %
Stability of test compound:	The stability of the test item at storage conditions was guaranteed until the expiry date Jan 1993.

2. Control material:

Negative control:	Untreated cell cultures which were cultivated in cultivation medium only were included in each experiment.
Solvent (vehicle) control:	As culture medium was used as solvent for the test item, the solvent control represents actually the negative control.
Positive controls:	2-Acetylaminofluorene (2-AAF), 3 µg/mL in DMSO

3. Hepatocyte isolation:

Primary rat hepatocytes were isolated by *in situ* collagenase perfusion from the livers of adult male F344 rats. A total of two rats were used in the study, using one rat for each experiment. The rats were approximately 15 – 19 weeks old and weighed 315.4 and 345.6 g. The animals were anesthetised with 60 mg/kg bw pentobarbital, perfused with a collagenase solution and the liver lobes were combined to isolate hepatocytes from the perfused livers. Finally, the cell viabilities were determined prior to plating.

4. Cell culture:

Cell culture establishment:	Freshly isolated hepatocytes were seeded in plating medium at a density of 3 x 10^5 cells. The cells were inoculated into numbered six-well culture dishes containing coverslips. The cells were allowed to attach for 1.5 - 2 hours and afterwards washed with culture medium.

Plating medium: William's medium E, supplemented with 10 % fetal bovine serum, 2 mM L-glutamine and 50 µg/mL gentamycin

Treatment medium: *William's medium E, supplemented with 2 mM L-glutamine, 50 µg/mL gentamicin and 10 µCi/mL tritiated thymidine (^{3}H-TdR, 80 Ci/mmol)*

Incubation: *At 37 °C in a humidified atmosphere containing 5 % CO_2.*

4. Test concentrations:

Experiment	Concentrations	Replicates
First experiment:	5, 10, 50, 100, 500, 1000, 2500 and 5000 µg/mL	Triplicate
Second experiment:	5, 10, 50, 100, 250, 500, 1000, 2500, 3800 and 5000 µg/mL	Triplicate

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 20 Jun – 18 Sep 1991

Finalisation date: 04 Dec 1991

2. Cytotoxicity

Cytotoxicity of the test substance was assessed via visual inspection by light microscopy. Cultures were characterised as "good" (normal cell morphology, sufficient attachment of cells to easily permit scoring of cells), "sparse" (most cells showed normal morphology but attachment of cells was < 25 % of control attachment), "pyknotic nuclei" (a large proportion of cells had small, darkly stained nuclei) or "cytotoxic" (few or no cells present on coverslips, or virtually all cells had pyknotic nuclei or other obvious morphologic effects such as damaged cell membranes or absence of cytoplasm).

6. Unscheduled DNA synthesis

Cell treatment:
Two independent experiments using hepatocytes of different rats were performed. The purpose of the first experiment was to determine cytotoxicity and to interpret any UDS response. On the basis of the cytotoxicity results from the first experiment, a second experiment was performed to confirm the results of the first. After cell culture establishment, triplicate cultures of the hepatocytes were cultivated in ^{3}H-TdR enriched treatment medium. In the first experiments, hepatocytes were exposed for 19 hours at 37 °C to eight test item concentrations in the range of 5 to 5000 µg/mL. In the second experiment, the cells were treated under identical conditions to ten test item concentrations in the range of 5 to 5000 µg/mL. In both experiments, solvent and positive controls (3 µg/mL 2-acetylaminofluorene) were included. After exposure, all cultures were washed with culture medium and processed for slide preparation.

Cell harvest and slide preparation:
Immediately following treatment, the cells were swelled in 1 % sodium citrate solution, fixed in 1:3

glacial acetic acid / ethanol and washed with deionised water. The coverslips were mounted on slides and dipped in Kodak NTB-2 photographic emulsion for 7 days at -20 °C before development. Subsequently, cells were stained with 1 % methyl-green pyronin Y, dried, coverslipped and evaluated.

Evaluation:
Primary hepatocyte DNA repair was determined by quantitative audioradiographic grain counting. The net increase in nuclear grains was quantified for at least 30 morphologically unaltered cells on a randomly selected area of each slide. Three slides per condition were scored. The higher count from two nuclear sized areas over the most heavily labeled cytoplasmic areas adjacent to the nucleus was subtracted from the nuclear count to give the net grains per nucleus. The percentage of cells in repair (cells showing at least 5 nuclear grains) was calculated for each concentration.

4. Statistics:
No statistical methods were used for the evaluation of data.

5. Acceptance criteria:
Data were considered acceptable if the mean number of net grains per nucleus and the percentage of cells in repair values of the solvent control were within the normal range of the laboratories historical control data and if the positive control produced an unscheduled DNA response of greater than 5.0 net grains per nucleus.

3. Evaluation criteria:
A substance was considered unequivocally positive for unscheduled DNA synthesis if the mean net grain count for any dose was greater than 5.0 nuclear grains per cell.
A substance was considered unequivocally negative if the mean net grain count was less than 0 nuclear grains per cell and the percentage of cells in repair was less than 10 % for all groups.
When results fell within 0 to 5 nuclear grains per nucleus or when the percentage of cells in repair exceeded 10 %, the presence of a dose response, the frequency distribution of cellular responses, increases in percentage of cells in repair and reproducibility data among concentrations were considered.

H. RESULTS AND DISCUSSION

1. ANALYTICAL DETERMINATIONS
Analytical determinations have not been performed in the study. Solubility tests with AMPA in culture medium, DMSO, acetone and ethanol were performed prior to the study. Culture medium allowed the highest possible test concentration of 5000 µg/mL and was selected as solvent for the unscheduled DNA synthesis assay.

2. CYTOTOXICITY
Cytotoxicity was observed at 5000 µg/mL in the first experiment and at 3800 and 5000 µg/mL in the second experiment.

3. SOLUBILITY
Precipitation of the test item in culture medium was not reported.

4. UNSCHEDULED DNA SYNTHESIS
In both experiments, AMPA did not induce significant increases in the mean number of net nuclear grain counts in rat hepatocytes when compared to those of the solvent control at any tested concentration. In triplicate cultures per condition, the values for nuclear grains per nucleus were negative and the percentage of cells in repair was ≤ 6 % up to the highest concentration tested.
Values obtained for the solvent and the positive control were as expected, demonstrating the validity and the sensitivity of the test system.

III. CONCLUSIONS

Based on the results of the present study, AMPA, metabolite of glyphosate did not induce unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, AMPA was negative for unscheduled DNA synthesis in primary rat hepatocytes *in vitro*.
The study was conducted in accordance with GLP and similar to OECD guideline 482 (1986), which was deleted in 2014. The study was considered to provide supporting information only because the Unscheduled DNA Synthesis (UDS) assay is no longer a standard method described by current guidelines. There were no deviations when compared to the previous OECD guideline 482 (1986).

Assessment and conclusion by RMS:

Genotoxicity – *in vivo*

1. Information on the study

Data point	CA 5.8.1/026
Report author	[redacted]
Report year	1993
Report title	Mutagenicity test: Micronucleus test with AMPA, batch 286-JRJ-73-4
Report No	13268
Document No	146-GLY
Guidelines followed in study	OECD 474 (1983), US EPA 40 CFR part 700 (F) § 798.5395 (1987)
Deviations from current test guideline (OECD 474, 2016)	According to the current guideline OECD 474 (2016), at least 4000 polychromatic erythrocytes per animal should be evaluated for the presence of micronuclei. However, in the present study only 1000 polychromatic erythrocytes were evaluated. The percentage of polychromatic erythrocytes among total erythrocytes was determined for 200 erythrocytes instead of 500 erythrocytes. Only a single dose was tested. Although bone marrow toxicity was observed, no lower dose levels were additionally tested. In addition, no 24-hour control animals were included (first sampling time point). No data on proficiency and/or historical control data were provided and acceptance and evaluation criteria were not specified in the study report.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (4L docs)	Category 2a

2. Full summary

Executive summary

AMPA, metabolite of glyphosate (batch: 286-JRJ-73-4, purity: 99.2 %) was tested for its clastogenic potential in NMRI mice in a micronucleus test. Based on the results of an initial toxicity study in which no signs of toxicity became evident, the micronucleus test was performed at a dose level of 5000 mg/kg bw.

The test item was dissolved in 0.9 % NaCl with 1 % carboxymethyl cellulose and administered as a single dose to groups of 5 mice/sex at a constant dosage volume of 20 mL/kg bw. Similar constituted groups of 5 mice/sex received the positive (cyclophosphamide, 30 mg/kg bw) or vehicle control (0.9 % NaCl with 1 % carboxymethyl cellulose).
Bone marrow sampling of the test item treated groups was performed 24, 48 and 72 hours after treatment. Positive and vehicle control animals were sacrificed 24 and 48 hours after dosing, respectively. Smears were prepared from the femoral bone marrow of each animal and 1000 immature erythrocytes (PCE) per animal were scored for the presence of micronuclei. The percentage of PCEs in 200 erythrocytes was calculated. In addition, the number of micronucleated normochromatic erythrocytes (NCEs) was determined.
Oral administration of 5000 mg/kg bw AMPA was associated with a clear depression of erythropoiesis, as the ratio of PCE to NCE was significantly decreased when compared to solvent control animals.
Upon treatment with AMPA there was no statistically significant increase in the frequency of micronucleated PCEs at any sampling time point when compared to those of control animals. The incidence of micronucleated PCEs in the solvent and positive control groups were in accordance with the laboratory's historical control data, confirming the sensitivity of the test and demonstrating the capability of the test animals to respond to mutagenic substances.
Based on the experimental findings, AMPA, metabolite of glyphosate is negative for cytogenetic effects in bone marrow in mice *in vivo*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	AMPA, metabolite of glyphosate
Description:	White powder
Lot/Batch #:	286-JRJ-73-4
Purity:	99.2 %
Stability of test compound:	The stability of the test item at storage conditions (at room temperature in the dark) was guaranteed for at least 3 years. The stability of the test item in solvent was not specified.
Solvent (vehicle) used:	1 % carboxymethyl cellulose (CMC) in 0.9 % NaCl

2. Control materials

Solvent (vehicle) control:	1 % carboxymethyl cellulose (CMC) in 0.9 % NaCl
Positive control:	Cyclophosphamide, 30 mg/kg bw

3. Test animals:

Species:	Mouse
Strain:	Bom:NMRI
Sex:	Male and female
Source:	[redacted]
Age at study initiation:	8 weeks
Weight at dosing:	25 - 37 g
Acclimation period:	5 days
Diet/Food:	Altromin 1314 (Chr. Petersen Ltd., Ringsted, Denmark), *ad libitum*

Water:	Tap water acidified with hydrochloric acid to pH 2.5, *ad libitum*
Housing:	In groups of 5/sex in Macrolon type III cages measuring 420 x 260 x 150 mm with pinewood softwood sawdust bedding.

6. Environmental conditions:

Temperature:	21 ± 3 °C
Humidity:	55 ± 15 %
Air changes:	Approximately 10/hour
Photoperiod:	12-hour light and dark cycle

7. Test concentrations and treatment groups:

c) Preliminary toxicity study

Dose levels:	5000 mg/kg bw
Concentrations:	250 mg/mL
Dose volume:	20 mL/kg bw
Number of animals:	3/sex
Route of administration:	Oral gavage

d) Main micronucleus test

Dose levels:	5000 mg/kg bw
Concentrations:	250 mg/mL
Dose volume:	20 mL/kg bw
Number of animals:	5/sex/group
Route of administration:	Oral gavage

B. STUDY DESIGN AND METHODS

3. Dates of experimental work: 26 Oct - 12 Nov 1992
Finalisation date: 18 Feb 1993

4. Animal assignment and treatment:

Preliminary toxicity study:
AMPA, metabolite of glyphosate was expected to be of low toxicity. To determine the maximum tolerated dose, a single dose of 5000 mg/kg bw was administered by oral gavage to 3 mice/sex. Each one male and one female mouse were sacrificed 24, 48 and 72 hours after dosing and bone marrow smears were prepared. For each animal, the percentage of polychromatic erythrocytes among the total of erythrocytes was determined for 200 erythrocytes.
Based on the results of the preliminary toxicity study, 5000 mg/kg bw was selected as dose level for the main micronucleus test.

Main micronucleus test:
Groups of 5 mice/sex received a single dose of 5000 mg/kg bw by oral gavage at a constant dosage volume of 20 mL/kg bw. Similar constituted groups of 5 mice/sex received the vehicle (0.9 % NaCl with 1 % carboxymethyl cellulose) or the positive control (30 mg/kg bw cyclophosphamide, administered via intraperitoneal injection).
At 24, 48 and 72 hours after treatment, each one group of animals was sacrificed by cervical dislocation and bone marrow smears were prepared. Positive control animals were sacrificed 24 hours after treatment, whereas the vehicle control group was sacrificed 48 hours after dosing.

5. Slide preparation:

Immediately after sacrifice, the right femoral bone was dissected, the proximal end of the femur was cut and marrow cells were flushed out with foetal calf serum. After whirl-mixing, the bone marrow cells were centrifuged and smears were prepared. The specimens were fixed in methanol and stained with May-Grünwald/Giemsa.

6. Slide evaluation:

Slides were randomly coded and examined by microscopical analysis. About 1000 polychromatic erythrocytes (PCE) per animal were scored for the presence of micronuclei. The percentage of PCEs in 200 erythrocytes was calculated. In addition, the number of micronucleated normochromatic erythrocytes (NCEs) was determined during the counting of 1000 PCEs.

7. Statistics:

The number of micronucleated PCEs in the test group were compared to the number found in the vehicle group. Statistical analysis was performed using the one-way analysis of variance performed on the values transformed to normal scores according to Blom's method[33].

8. Acceptance criteria:

Acceptance criteria were not specified in the study report.

9. Evaluation criteria:

Evaluation criteria were not specified in the study report.

II. RESULTS AND DISCUSSION

D. ANALYTICAL DETERMINATIONS

Analytical determinations of the test substance in vehicle were not performed.

E. PRELIMINARY TOXICITY STUDY

Clinical signs of systemic toxicity were not described in the study report. Bone marrow toxicity, evident as a reduced ratio of polychromatic (PCE) to normochromatic erythrocytes (NCE) was observed to a minor degree. Between 32 – 46 % of PCE were found in the animals, indicating that erythropoiesis was not or only slightly affected.

Based on the results of the preliminary toxicity study, 5000 mg/kg bw was selected as dose level for the main micronucleus test.

F. MAIN MICRONUCLEUS TEST

Systemic toxicity:

Mortality:

No mortality occurred.

Clinical signs of toxicity:

Clinical signs of toxicity have not been described in the study report.

Evaluation of bone marrow slides:

The percentage of polychromatic erythrocytes (PCEs) in AMPA-treated animals was statistically significantly lower than in control animals, indicating a clear depression of erythropoiesis and demonstrating that bone marrow toxicity was evident.

In addition, there was no statistically significant increase in the frequency of micronucleated PCEs (mPCEs) of test item-treated animals at any sampling time point when compared to those of control

[33] Blom, 1958: Statistical Estimates and Transformed Beta Variables, New York: John Wiley and Sons, Inc.

animals. Although there was a slight trend towards an increase in mPCE in test item-treated males with later sampling time points, the values remained within those of control animals, were not significant and standard deviations were comparably low. The incidence of micronuclei in the solvent and positive control groups were in accordance with the laboratory's historical control data, confirming the sensitivity of the test and demonstrating the capability of the test animals to respond to mutagenic substances.

Table 5.8.1-59: Summary of genotoxicity data for AMPA obtained in the micronucleus test in mice ([redacted] 1993)

Treatment	Dose (mg/kg bw)	Sampling time	Males		Females	
			mPCE ± SD# /1000 PCE	mean %# PCE ± SD / 200 erythrocytes	mPCE ± SD# /1000 PCE	mean %# PCE ± SD / 200 erythrocytes
CMC	20 mL/kg bw	48 h	0.80 ± 0.45	36.40 ± 2.61	0.20 ± 0.45	34.40 ± 2.97
Test item	5000	24 h	0.20 ± 0.45	28.20 ± 5.63	0.20 ± 0.45	25.20 ± 1.79
Test item	5000	48 h	0.60 ± 0.55	28.80 ± 4.92	0.20 ± 0.45	28.40 ± 3.21
Test item	5000	72 h	0.80 ± 0.45	26.60 ± 5.03	0.40 ± 0.55	24.20 ± 1.64
CPA	30	24 h	12.40 ± 2.07	35.00 ± 2.55	13.08 ± 3.03	33.40 ± 4.16

mPCE: micronucleated polychromatic erythrocytes
CMC: carboxymethyl cellulose, solvent control; CPA: cyclophosphamide, positive control
#: all values wre re-calculated based on raw data of individual animals provided in the study report.

III. CONCLUSIONS

Based on the experimental findings, AMPA, metabolite of glyphosate did not induce micronuclei in the bone marrow of mice *in vivo*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, AMPA was negative for clastogenic effects in the bone marrow of male and female NMRI mice *in vivo*.
The study was conducted under GLP and in accordance with OECD guideline 474 (1983). There were a number of deviations when compared to the current OECD guideline 474 (2016). Only 1000 polychromatic erythrocytes (PCE) were investigated per animal. However, the number of micronucleated PCE did not exceed those of control animals, standard deviations were comparably low and the values were statistically not significant when compared to control conditions. Thus, the test result was considered to be clearly negative. In addition, the percentage of polychromatic erythrocytes among total erythrocytes was determined for 200 erythrocytes instead of 500 erythrocytes and control animals were not included for the first sampling time point. These and further deviations were considered to be of minor degree and to not compromise the validity of the study. Therefore, the study is considered valid and acceptable.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/027
Report author	[redacted]
Report year	1993
Report title	Mouse Micronucleus Study of AMPA
Report No	[redacted]-13243
Document No	EHL-90170 / ML-90-404
Guidelines followed in study	The study was performed similarly to OECD 474 (2016)
Deviations from current test guideline (OECD 474, 2016)	According to the current guideline OECD 474 (2016), at least 4000 polychromatic erythrocytes per animal should be evaluated for the presence of micronuclei. However, in the present study only 1000 polychromatic erythrocytes were evaluated. The animals were dosed via intraperitoneal injection, which is not representative for a human route of exposure. A justification for the route of administration was not given. Although there was no concurrent proof for bone marrow exposure, signs of systemic toxicity were observed and it can be assumed that bone marrow exposure was achieved by the intraperitoneal injection. Historical control data for positive control animals were not included. Acceptance criteria were not specified and evaluation criteria mentioned were inconsistent with those recommended by the guideline.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

AMPA, metabolite of glyphosate (batch: HET-9001-1463T, purity: 94.38 %) was tested for its clastogenic potential in CD-1 mice in a micronucleus test. In two initially performed toxicity studies, in which clinical signs of toxicity and mortality were observed at ≥ 606 mg/kg bw, a LD_{50} of 1357.7 mg/kg bw was determined. 1000 mg/kg bw (representing approx. 74 % of the LD_{50}) was selected as top dose level for the main micronucleus study.

The test item was dissolved in corn oil and administered as a single intraperitoneal injection to groups of 5 mice/sex at dose levels of 100, 500 and 1000 mg/kg bw. Similarly constituted groups of 5 mice/sex received the solvent or the positive control (cyclophosphamide, 40 mg/kg bw).

Bone marrow sampling of the test item and solvent control treated groups was performed 24, 48 and 72 hours after treatment. Positive control animals were sacrificed 24 hours after dosing. Smears were prepared from the femoral bone marrow of each animal and 1000 polychromatic erythrocytes (PCE) per animal were scored for the presence of micronuclei. In addition, the percentage of PCEs among a total of 1000 erythrocytes was determined.

Intraperitoneal injection of AMPA induced signs of systemic toxicity, evident as listlessness, in 6/15 males and 1/15 females at 500 mg/kg bw and in 13/15 males and 3/15 females at 1000 mg/kg bw. The symptoms were observed until study termination. In addition, body weight development was statistically significantly impaired in mid and high dose males of the 48-hour sampling time point and in high dose

group females of the 72-hour sampling time point. The findings were attributed to treatment and considered toxicologically relevant.
Although bone marrow exposure can be assumed, due to the observations on systemic toxicity, there was no bone marrow toxicity in terms of a decreased PCE/total erythrocyte ratio observed in any AMPA treated group and for any sampling time point.
A statistically significant increase in the frequency of micronucleated PCEs when compared to solvent controls was observed for females at 100 mg/kg bw at the 72 hour sampling time point. The values were within the range of the laboratories historical control data and showed no dose-response relationship, therefore the finding was not attributed to treatment. There was no statistically significant increase in the mean number of micronucleated PCEs observed for any other male or female dose group at any other sampling time point.
The incidence of micronucleated PCEs in the solvent controls remained within the range of historical control data, whereas those of the positive controls showed a marked increase of statistical significance. The results obtained for the solvent and positive controls thus confirmed the sensitivity of the test and demonstrated the capability of the test animals to respond to mutagenic substances.
Based on the experimental findings, AMPA, metabolite of glyphosate is negative for cytogenetic effects in bone marrow in mice *in vivo*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Aminomethylphosphonic acid (AMPA, metabolite of glyphosate)
Identification:	AMPA
Description:	White solid
Lot/Batch #:	HET-9001-1463T (Test sample T900031)
Purity:	94.38 %
Stability of test compound:	The stability of the test item at storage conditions (at room temperature in the dark) was guaranteed until the expiry date Jan 1993. The stability of the test item in solvent was not specified.
Solvent (vehicle) used:	Corn oil
2. Control materials	
Solvent (vehicle) control:	Corn oil
Positive control:	Cyclophosphamide monohydrate, 40 mg/kg bw in Hank's balanced salt solution (HBSS)
3. Test animals:	
Species:	Mouse
Strain:	CD-1
Sex:	Male and female
Source:	[redacted]
Age at study initiation:	7 – 10 weeks
Weight at dosing:	27.9 – 38.7 (males) and 21.5 – 33.2 (females)
Acclimation period:	Minimum 7 days
Diet/Food:	Purina Certified Laboratory Rodent Chow® No. 5002 (Purina Mills Inc., St. Louis, Missouri), *ad libitum*
Water:	Tap water from the public water supply, *ad libitum*

Housing:	Individually in stainless steel cages with stainless steel mesh bottoms.

4. Environmental conditions:

Temperature:	64 - 79 °F (18 – 26 °C)
Humidity:	40 - 70 %
Air changes:	Not specified
Photoperiod:	12-hour light and dark cycle

5. Test concentrations and treatment groups:

e) First preliminary toxicity study

Dose levels:	1000 and 5000 mg/kg bw
Concentrations:	Not specified
Dose volume:	10 mL/kg bw
Number of animals:	2/sex/dose level
Route of administration:	Intraperitoneal injection

f) Second preliminary toxicity study

Dose levels:	303, 606, 1250, and 2500 mg/kg bw
Concentrations:	Not specified
Dose volume:	10 mL/kg bw
Number of animals:	3/sex/dose level
Route of administration:	Intraperitoneal injection

g) Main micronucleus test

Dose levels:	100, 500 and 1000 mg/kg bw
Not specified	Not specified
Dose volume:	10 mL/kg bw
Number of animals:	5/sex/group
Route of administration:	Intraperitoneal injection

B. STUDY DESIGN AND METHODS

1. **Dates of experimental work:** 20 Aug – 24 Oct 1990
   Finalisation date: 08 Dec 1993

2. **Animal assignment and treatment:**

Preliminary toxicity studies:

An initial range-finding experiment was conducted using 2 mice/sex/dose level. A single dose of 1000 or 5000 mg/kg bw was administered via intraperitoneal injection at a constant dosage volume of 10 mL/kg bw. Afterwards, the animals were observed for mortality and clinical signs of toxicity during a 4-days observation period.

Based on the results of the first preliminary toxicity study, a second toxicity study was performed prior to the main micronucleus assay in order to estimate the maximum tolerated dose (MTD). In the second preliminary study, groups of 3 mice/sex were injected with test item concentrations in the range of 303 - 2500 mg/kg bw. After dosing, the animals were also observed for clinical signs of toxicity and mortality. Each 1/3 males and 1/3 females of the 303 and 606 mg/kg bw dose group and 1/3 females of the 1250 mg/kg bw dose group were sacrificed 24 hours after dosing for erythrocyte evaluation (data

not provided in study report). The remaining animals were observed for three further days.
LD_{50} values and the maximum tolerated dose were estimated with the data obtained in both preliminary experiments. Based on the findings of the two initial toxicity studies, the dose levels for the main micronucleus study were selected.

Main micronucleus test:
Groups of 5 mice/sex received a single AMPA dose of 100, 500 or 1000 mg/kg bw via intraperitoneal injection. The test item was administered at a constant dosage volume of 10 mL/kg bw. Similarly constituted groups of 5 mice/sex received the vehicle (corn oil) or the positive control (40 mg/kg bw cyclophosphamide).
Each one group of test item-treated or vehicle control animals was sacrificed by cervical dislocation 24, 48 and 72 h after treatment, followed by preparation of bone marrow smears. Positive control animals were sacrificed 24 hours after treatment.

3. Slide preparation:
After sacrifice, the femora of the animals were removed, cut and marrow cells were flushed out with fetal bovine serum. The cells were centrifuged and smears were prepared. For each animal two slides were prepared. The slides were allowed to air-dry over night and stained with Wright-Giemsa Stain Pak by using a Hema-Tek II slide staining machine.

4. Slide evaluation:
Slides were randomly coded prior to analysis. For each animal, a total of 1000 erythrocytes was evaluated for the amount of polychromatic (PCE) among total erythrocytes and about 1000 PCEs were scored for the presence of micronuclei. PCEs containing more than one micronucleus were scored as single micronucleated PCE (mPCE). In a few cases significant discordance in mPCE frequency were initially observed between two slide scorers (e.g. a difference of 4 or more mPCE). In these cases slides were rescored to determine if the discordance was reproducible and the rescored values were used for reporting and analysis.

5. Statistics:
LD_{50} estimates were calculated using the Probit method on toxicity range-finding data. The individual test animal was used as the individual unit for analysis of micronucleated polychromatic erythrocyte (PCE) frequency, PCE/total erythrocyte ratio and body weight change. Micronucleated PCE frequencies per animal were transformed as the square root prior to analysis (Snedecor and Cochran[34] (1967) and MacGregor[35] et al. (1987)). PCE/total erythrocyte ratios were not transformed. A Dunnett's test (one sided) was used for comparison of treatment group and positive control values with solvent control values.

6. Acceptance criteria:
Acceptance criteria were not specified in the study report.

7. Evaluation criteria:
Evaluation criteria were not specified in the study report. A test item was considered to induce a statistically significant, treatment-related response in micronuclei formation if the following criteria were met:

- There was a dose- and time-dependent effect, which was consistent with a treatment-induced response.
- The degree of the response was in relation to both concurrent and historical negative and positive control data.

II. RESULTS AND DISCUSSION

[34] Snedecor, G.W. and Cochran, W. G. (1967) Statistical Methods, 6th edition, 223-226 and 325-327, Iowa State Press, Ames, Iowa.

A. ANALYTICAL DETERMINATIONS

Analytical determinations were not performed in the present study.

B. PRELIMINARY TOXICITY STUDY

In the first preliminary toxicity study, mortality was observed in 2/2 males and 1/2 females at 1000 mg/kg bw 3 and 4 days following treatment and in 2/2 males and 2/2 females at 5000 mg/kg bw within the first two days after dosing. During the 4-day observation period until death, all animals showed ante-mortem signs of systemic toxicity which included listlessness and unresponsiveness.

In the second preliminary toxicity study, mortality was noted in 1/2 males and 0/2 females at 606 mg/kg bw on study Day 4, in 2/3 males and 0/2 females at 1250 mg/kg bw on study Days 2 and 3 and in 2/3 males and 1/3 females at 2500 mg/kg bw on study Day 2, respectively. Clinical signs of toxicity, evident as listlessness or unresponsiveness were noted in 2/2 males at 606 mg/kg bw on study Days 3 and 4, in 2/3 males and 3/3 females at 1250 mg/kg bw throughout the whole observation period and in 3/3 males and 2/3 females at 2500 mg/kg bw throughout the whole observation period.

The LD_{50} for male and female mice combined was calculated to be 1357.7 mg/kg bw. Based on the results of the two preliminary toxicity studies, 1000 mg/kg bw (representing approx. 74 % of the LD_{50} value) was selected as maximum tolerated dose level for the main micronucleus test.

C. MAIN MICRONUCLEUS TEST

Systemic toxicity:

Mortality:

No mortality occurred.

Clinical signs of toxicity:

Listlessness was observed in 6/15 males and 1/15 females at 500 mg/kg bw and in 13/15 males and 3/15 females at 1000 mg/kg bw. The symptoms were present until study termination up to 72 hours after dosing. No clinical signs of toxicity were observed at the 100 mg/kg bw dose group or in solvent control animals.

Body weight development:

Statistically significant decreases in mean body weight change were observed for the mid (500 mg/kg bw) and high dose (1000 mg/kg bw) test group in males sacrificed 48 hours after dosing and for the mid dose group in females sacrificed 24 and 72 hours after dosing. The impaired body weight development in males of the 48-hour sampling time point exhibited a dose-response pattern. Thus, the observations were attributed to treatment and considered toxicologically relevant.

Table 5.8.1-60: Body weight development after treatment with AMPA, observed in the micronucleus test in mice ([redacted], 1993)

Treatment	Dose (mg/kg bw)	Sampling time	Mean BW change [g] mean ± SD

CPA: cyclophosphamide, positive control
BW: body weight
* $p \leq 0.05$ and ** $p \leq 0.01$ by one-sided Dunnett's test

Evaluation of bone marrow slides:
There was no statistically significant decrease in the mean polychromatic erythrocytes (PCE)/total erythrocytes ratio for any of the AMPA treated or control groups at any sampling time point, indicating that no bone marrow toxicity was evident. However, as clinical signs of toxicity were observed in AMPA-treated animals of the 500 and 1000 mg/kg bw groups, it can be assumed that bone marrow was exposed.
A statistically significant increase in the frequency of micronucleated PCEs when compared to solvent controls was noted for females at the low dose level (100 mg/kg bw) at the 72 hour sampling time point. The values were within the range of the laboratories historical control data and showed no dose-response relationship, therefore the finding was not considered to reflect a treatment-related effect. There was no statistically significant increase in the mean number of micronucleated PCEs observed for any other male or female dose group at any other sampling time point.
The incidence of micronuleated PCEs in the solvent controls remained within the range of historical control data. The positive control (cyclophosphamide) yielded expected positive responses in micronucleated PCE frequency, indicating the adequacy of the experimental conditions.

Table 5.8.1-61: Summary of genotoxicity data for AMPA obtained in the micronucleus test in mice ([redacted], 1993)

III. CONCLUSIONS

Based on the experimental findings, AMPA, metabolite of glyphosate did not induce micronuclei in the bone marrow of mice *in vivo*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

The study was conducted in compliance with GLP and similar to OECD guideline 474 (2016), although some deviations became evident. The number of polychromatic erythrocytes (PCE) evaluated was less than the 2000 PCE which are recommended by the current guideline. Based on the evaluation of 1000 PCE/animal, the test item was considered negative for clastogenic effects in the bone marrow of male and female CD-1 mice *in vivo*. Although there was a statistically significant increase in the frequency of micronucleated polychromatic erythrocytes (PCE) in females at the low dose level (100 mg/kg bw) at the 72 hour sampling time point, the values were within the range of the laboratories historical control data and showed no dose-response relationship. Thus, the finding was not considered to reflect a treatment-related effect. It can be assumed that the negative test result obtained in the study would be the same if more cells were evaluated.

With regard to the positive controls, male animals showed a distinct increase in mPCEs of statistical significance. In 2/5 positive control females no induction of micronuclei in PCEs was observed, while a marked increase in mPCEs was observed for the remaining 3/5 positive control females. This finding was not mentioned or further discussed in the study report. However, a statistically significant increase in mPCE was still observed when combining the data of all 5 animals. Therefore, the results obtained were considered to confirm the sensitivity of the test and to demonstrate the capability of the test animals to respond to mutagenic substances.

Although bone marrow toxicity, indicated by a decreased PCE to normochromatic erythrocyte (NCE) ratio, was not observed, clinical signs of toxicity indicated systemic availability of the test substance. In addition, the test item was administered by intraperitoneal injection, therefore it can be assumed that bone marrow exposure was achieved.

Further deviations were of minor degree and considered to not compromise the validity of the study. The study is therefore considered valid and acceptable.

Assessment and conclusion by RMS:

Reproductive toxicity

Developmental toxicity

1. Information on the study

Data point	CA 5.8.1/028
Report author	[redacted]
Report year	1992
Report title	AMPA: Teratogenicity study in rats
Report No	7891
Document No	124-GLY
Guidelines followed in study	US EPA Pesticide Assessment Guidelines Subdivision F, 83-3
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: weight and histopathological changes of the thyroid glands, foetal anogenital distance (AGD), indication of incomplete testicular descent/cryptorchidism in male foetuses; blood samples from dams to assess thyroid hormons (T4, T3 and TSH) were not collected.
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Executive summary

This developmental study in rats was performed in two successive replicates, the first containing 10 mated females per treatment group, the second a further 15 females per group. For each replicate, mated female Sprague Dawley rats were randomised into four treatment groups. The animals were dosed by gavage once daily over Days 6-16 inclusive of gestation, where Day 0 was the day of detection of mating. Dose levels of test material were as follows: 0, 100, 350 and 1000 mg/kg bw/day. The animals were monitored during gestation for clinical signs of toxicity and for body weight and food consumption performance. They were sacrificed on Day 20 of gestation and the conceptuses were evaluated. The live foetuses were subsequently examined for developmental abnormalities and variants of the viscera and skeleton, including the state of skeletal ossification.

There was no evidence of toxicity in either the dam or embryo-fetal development at any of the dose levels applied.

A. MATERIALS

1. **Test material:** AMPA

Description:	white powder
Lot/Batch number:	286-JRJ-73-4
Purity:	99.2 %
CAS#:	1066-51-9
Stability of test compound:	Stable until 09-Jun-1995

2. Vehicle:	0.5 % carboxymethylcellulose (CMC) in distilled water
3. Test animals:	
Species	Rat
Strain	Sprague-Dawley CD
Age/weight on arrival	Approximately 9 weeks / approx. 250 g
Source	[redacted]
Housing	Individually, in polypropylene cages (42 x 27 x 20 cm), with a stainless steel grid bottom, top and food hopper
Acclimatisation period	3-5 days
Diet	Rat and Mouse Breeder Diet No. 3 (Expanded) SQC (Special Diets Services (SOS) Limited), *ad libitum*
Water	Mains water, *ad libitum*
Environmental conditions	Temperature: 20 ± 2°C Humidity: 50 ± 15 % Air changes: 15 - 20 changes / hour Photoperiod: 12 hours light / 12 hours dark

B. STUDY DESIGN AND METHODS

Dates of Experimental work: Not reported

In-life dates: Not reported (QA audits conducted between March 1992 and July 1992)

Mating procedure: Mating was on the basis of two females to each male, female siblings not being paired with the same male. For each female, cohabitation with a male was continuous until mating was detected. A vaginal lavage was examined each morning and the day of detection of sperm in the lavage, or of a copulatory plug in situ, was considered as Day 0 of gestation. A record was kept of the male which inseminated each female.

Animal assignment: On detection of mating, the females were re-housed in an individual cage and allocated to a treatment group using a computer-generated series of randomly sequenced numbers representing the treatment groups.

Dose selection rationale: Dose levels were agreed with the Sponsor after evaluation of existing toxicity data. These data indicated that the material in rats has a low toxic potential, with a lowest effect level (LEL) of 1200 mg AMPA/kg bw/day by dietary administration and an oral LD_{50} of approximately 8000 mg AMPA/kg bw. It was considered appropriate to proceed with the teratogenicity study using the conventional 'limit' dose of 1000 mg AMPA/kg bw/day as the highest dose level.

Dose preparation and analysis: The test item was formulated as a part-solution, part-suspension, the vehicle being a 0.5 % solution of carboxymethylcellulose (CMC) in distilled water. Fresh formulations were prepared daily, each concentration being prepared separately. The requisite quantity of test item was weighed into a labelled container. The necessary volume of vehicle was added, and mixing was by means of a Silverson laboratory mixer/emulsifier. The undissolved material was maintained in suspension during dosing procedures by means of a magnetic stirrer.

Samples of dosing formulations were analysed at the IRI Analytical Chemistry Laboratory under the provisions of IRI Project No. 353917 (Method Establishment, homogeneity, accuracy and stability) and under Project No. 490421 (concentration accuracy and homogeneity of actual dosing formulations).

For each study replicate, triplicate samples of 1 mL were taken from each concentration on the first day of treatment, then again near the end of the treatment period.

Dosage administration: The mated females were dosed once daily, at approximately the same time each

day, over Days 6-16 inclusive of gestation, where Day 0 was the day of detection of mating.
Doses were administered orally, by gavage, at a volume of 10 mL/kg bw, using a steel dosing cannula. The volume of formulation administered to each female was determined each day by the weight of that animal as measured at the time of administration.

Clinical observations: All animals were checked for viability at the beginning of each day and again as late as possible on each day. All animals were examined for reaction to treatment on each day. The nature, onset, duration and intensity of any signs were recorded, based on a routine examination conducted 1-1.5 h after dosing, with any necessary follow-up examinations.

Bodyweight: Individual body weights were recorded on Days 0, 6, 9, 13, 17 and 20 of gestation.

Food consumption: The weight of the food consumed by each mated female was recorded daily throughout, commencing on Day 4 of gestation (weighed quantity first offered on Day 3 of gestation).

Terminal investigations: On Day 20 of gestation, the animals were killed by carbon dioxide asphyxiation. The contents of the thoracic and abdominal cavities were examined macroscopically for abnormalities. Any abnormal tissue was sampled and preserved in neutral buffered 10 % formalin, to facilitate any necessary histological analysis. The reproductive tract was removed and weighed intact, then opened and the contents were examined. The number of corpora lutea in each ovary and the number and position of all implantation sites in the uterus were recorded. Each implant was classified as being live, a foetal death (death judged to have occurred after ca. Day 16 of gestation), a late embryonic death (death judged to have occurred in the period ca. Day 12- Day 16) or an early embryonic death (death judged to have occurred prior to ca. Day 12).

Foetal observations: Each live foetus was individually identified within the litter and its weight was recorded. The foetuses were examined for externally visible abnormalities prior to fixation. Approximately one half of the foetuses from each uterus were fixed in methylated ethyl alcohol, and the remaining half in Bouin's fluid. Those foetuses fixed in alcohol were subsequently examined by open dissection for visceral abnormalities. The eviscerated carcasses were then cleared in potassium hydroxide and glycerol, and the skeletons were stained with Alizarin Red S. Skeletal structures in these foetuses were examined for abnormalities and variants, including state of ossification.

Those foetuses fixed in Bouin's fluid were examined for soft tissue abnormalities and variants by means of a freehand razor blade sectioning technique derived from that of Wilson.

The sex of each foetus was determined during the dissection procedures.

Statistical analyses: It was considered unnecessary to conduct any formal statistical tests on the data from this study. Interpretation was able to be based on examination of the individual and group mean values.

II. RESULTS AND DISCUSSION

A: ANALYSIS OF DOSE FORMULATIONS

Dose formulation analysis data show that the formulations used in the study were prepared to an acceptable level of accuracy, were homogeneous, and were stable for at least 24 hours.

B: CLINICAL OBSERVATIONS

One female at 1000 mg/kg bw/day was difficult to dose on Day 13 of gestation; salivation was noted at dosing but had ceased by 1 h post-dosing. For a second high dose animal a hard mass was noted associated with the left scapula. Post-mortem examination identified the mass as a 5 x 4 mm cartilaginous/bony outgrowth from left scapula, apparently non-neoplastic. These findings were considered incidental and not associated with treatment. In addition to these, there were sporadic findings common to this strain of animals (e.g. patches of alopecia, skin scabbing), there having been no relationship to treatment in their

incidence.

C. BODY WEIGHT

There was no effect of treatment with AMPA on maternal body weights.

Table 5.8.1-62: AMPA: Teratogenicity study in rats ([redacted], 1992): Summary of maternal body weight and body weight gain.

	Dose level of AMPA (mg/kg bw/day)			
Body weight (g ± S.D.) Day post coitum	**0 (control)**	**100**	**350**	**1000**

20	439 ± 37	439 ± 34	439 ± 35	447 ± 33
Body weight gain (g ± S.D.) Day 6-17 post coitum	83.5 ± 11.3	83.5 ± 12.2	83.8 ± 8.5	85.0 ± 15.3

S.D. = Standard deviation

D. FOOD CONSUMPTION

There was no effect of treatment with AMPA on maternal food consumption.

Table 5.8.1-63: AMPA: Teratogenicity study in rats ([redacted], 1992): Summary of maternal food consumption (g/animal/day)

	Dose level of AMPA (mg/kg bw/day)			
Food consumption Day post coitum	**0 (control)**	**100**	**350**	**1000**
6	31	30	30	29
13	34	33	34	35
17	38	36	38	39
19	30	32	34	32
Total consumption Days 6-17 post coitum	413	406	415	424

E. NECROPSY

Gross pathology: Not reported.

Maternal performance:

There was no effect of treatment on any of the examined parameters of pregnancy performance. In particular, there were no notable inter-group differences in the incidence of intra-uterine death, or in mean foetal weight.

Table 5.8.1-64: AMPA: Teratogenicity study in rats ([redacted], 1992): Intergroup comparison of maternal performance

Observation	Dose level of AMPA (mg/kg bw/day)			
	0 (control)	**100**	**350**	**1000**

F. FOETUSES

There was-no effect of AMPA on the number, growth or survival of the foetuses *in utero*.

Major and minor abnormalities of various kinds occurred sporadically in all treatment groups. None of the incidences exceeded the levels expected from this strain of animals in this laboratory, and no effect of treatment was noted.

Equally, the various parameters of skeletal ossification state were considered not to indicate an effect of treatment. None of the inter-group differences, taking parameters individually or collectively, were considered of sufficient magnitude to be of biological significance.

Table 5.8.1-65: AMPA: Teratogenicity study in rats ([redacted], 1992): Group incidence of major foetal abnormalities

Observation	Dose level of AMPA (mg/kg bw/day)			
	0 (control)	100	350	1000
	Incidence of foetuses (litters)			
Total no. of foetuses examined	414	383	372	402
Total no. of litters examined	25	25	24	24
Cleft palate, oedema; limb, digit and lung abnormalities ± diaphragmatic hernia	0	6 (1)	0	0
Right-sided aortic arch	0	0	0	1 (1)
Abnormalities of atlas and occipital bones	0	1 (1)	0	0
Interventricular septal defect	0	0	1 (1)	0
Partial situs inversus, interventricular septal defect	0	0	0	1 (1)
Forelimbs extended downwards ± carpal flexure, shortened and thickended ribs, shortened body oedema	5 (1)	6 (2)	0	0
Oedema, fused digits, misshapen genital papilla	0	0	0	1 (1)
Hydronephrosis	2 (2)	0	1 (1)	1 (1)

III. CONCLUSIONS

Treatment with AMPA at dose levels of up to 1000 mg/kg bw/day produced no evidence of toxicity in either the dam or the outcome of pregnancy.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study is considered acceptable although some endpoints that are requested in the OECD 414 TG

from 2018 are not included in this study. Treatment with AMPA at dose levels of up to 1000 mg/kg bw/day produced no evidence of toxicity in either the dam or embryo-fetal development. The dose level of 1000 mg AMPA/kg bw/day was considered the no observed effect level (NOAEL) in this study for both maternal and developmental effects.

Assessment and conclusion by RMS:

2. Full summary

The potential maternal toxicity and developmental toxicity of AMPA were evaluated in rats. AMPA in corn oil was administered to five groups of eight mated Sprague Dawley Crl:CD•BR rats once daily from gestation Days 6 through 15. Dosage levels were 125, 250, 500, 750 and 1000 mg/kg bw/day administered in a constant volume of 10 mL/kg bw. A concurrent control group, composed of eight mated females, received the vehicle, corn oil, on a comparable regimen at 10 mL/kg bw. The route of administration was oral by gastric intubation. Clinical observations and body weights were recorded. All animals were sacrificed on gestation Day 20 for a scheduled Caesarean section. The uteri and ovaries were examined and the numbers of foetuses, early and late resorptions, total implantations and corpora lutea were recorded. Mean gravid uterine weights and net body weight changes were calculated for each group. The kidneys, spleen and liver of each female were weighed. The foetuses were weighed, sexed, examined for external malformations and developmental variations and discarded.

All animals in the study survived to the scheduled necropsy. No compound-related clinical findings were observed at any dose level. There were no adverse effects at any dose level on mean body weights, body weight gains, gravid uterine weights, net body weight changes and organ weights. Treatment with AMPA had no apparent adverse effect on intrauterine growth and survival, and there were no external malformations or developmental variations observed in this study.

Based on the results of this study, dose levels of 150, 400 and 1000 mg/kg bw/day were considered suitable for the subsequent definitive developmental toxicity study of AMPA in rats.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	AMPA
Description:	white solid
Lot/Batch number:	HET-9001-1463T
Purity:	94.38 %
Stability of test compound:	Stable until Jan 1993
2. Vehicle:	Corn oil
3. Test animals:	
Species	Rat
Strain	Sprague-Dawley CD
Age on arrival	Approximately 10 weeks
Body weight at initiation of dosing	265 - 278 g (group mean values)
Source	[redacted]
Housing	Individually, in wire-mesh cages suspended above card board (except for mating when animals were housed pairwise)
Acclimatisation period	4 weeks
Diet	Purina® Certified Rodent Chow #5002, *ad libitum*
Water	Drinking water, *ad libitum*
Environmental conditions	Temperature: 70 - 73 °F (corresponding to 21 - 23 °C) Humidity: 59 ± 86 % Air changes: approximately 10 changes / hour Photoperiod: 12 hours light / 12 hours dark

B. STUDY DESIGN AND METHODS

In-life dates: 19 Jun 1990 – 14 Jul 1990

Mating procedure: At the end of the acclimatization period, animals judged to be in good health and meeting acceptable body weight requirements (a minimum of 220 grams) were placed in a suspended wire-mesh cage with a resident male from the same strain and source for breeding. Resident males were untreated, sexually mature rats utilized exclusively for breeding. A breeding record containing the male and female identification numbers and the dates of cohabitation was prepared. The females were approximately 14 weeks old when paired for breeding.
Positive evidence of mating was confirmed by the presence of a copulatory plug in the vagina or the presence of sperm in a vaginal smear. Each mating pair was examined daily. The day on which evidence of mating was identified was termed day 0 of gestation and the animals were separated.

Animal assignment: The mated females were consecutively assigned in a block design to groups containing eight rats each by the following randomization procedure. The first mated female and the appropriate gestation Day 0 designation were entered on the form and the female was assigned to group 1, the second mated female was assigned to group 2, and the third to group 3, etc. This process was continued daily until eight females were placed into each group. Body weight values ranged from 217 g to 285 g on Day 0 of gestation.

Dose preparation and analysis: An appropriate amount of the test item (AMPA) was weighed for each group into tared weigh boats and transferred to a mortar. The test material was triturated with corn oil, and ground with a pestle until a slurry was obtained. The slurry was transferred to a graduated cylinder via a series of vehicle rinses. A sufficient amount of vehicle was added to attain a volume of 250 mL. The cylinder was inverted several times to ensure adequate mixing and the contents were transferred to a properly labeled storage container. The cylinder was rinsed with an additional 100 mL of vehicle which was also added to the storage container. The preparations were then mixed for approximately 5 minutes on a Polytron PT6000 homogenizer to reduce particle size and to ensure proper mixing. The dosing

preparations were visually inspected for homogeneity prior to dispensation for the first day of dose administration.
Preparations for all dose groups were made once at study start, and were stored at room temperature. The preparations were stirred using a magnetic stir plate and bar each day prior to dispensing and during the dosing procedure.
Analysis of dose formulation was not performed in this dose range-finding study.

Dose administration: The dose formulations were administered orally by gavage, via a 16-gauge stainless steel gavage cannula, once daily for 10 consecutive days initiating on gestation Day 6 and continuing up to and including Day 15 of gestation. A dosage volume of 10 mL/kg bw was used for all dose levels. The control animals received corn oil on a comparable regimen of 10 mL/kg bw. Individual dosages were based on the most recent body weights.

Clinical observations: All animals were observed twice daily for moribundity and mortality. Detailed clinical observations were recorded individually from Days 0 through 20 of gestation (prior to compound administration during the dosing period). Animals were observed for signs of toxicity approximately one hour after treatment throughout the dosing period; all significant findings were recorded.

Bodyweight and gravid uterine weight: Maternal body weights were recorded individually on gestation Days 0, 6, 9, 12, 16, 18 and 20. A group mean body weight was calculated for each of these days. Mean body weight changes were calculated for each corresponding interval and for days 6-16, 16-20 and 0-20.
Gravid uterine weight, net body weight (the Day 20 body weight minus the weight of the uterus and contents) and net body weight change (the Day 0-20 body weight change minus the weight of the uterus and contents) were presented for each gravid female at the scheduled Caesarean section.

Food consumption: Food consumption was not recorded in this study.

Terminal investigations: All maternal animals were sacrificed by carbon dioxide inhalation on gestation Day 20. The thoracic, abdominal and pelvic cavities were opened by a ventral midline incision and the contents examined. In all instances, the post mortem findings were correlated with the ante mortem comments and any abnormalities were recorded. The uterus and ovaries were excised. The number of corpora lutea on each ovary was recorded. The trimmed uterus was weighed, opened and the number and location of all foetuses, early and late resorptions and the total number of implantation sites were recorded. Uteri with no macroscopic evidence of nidation were opened and subsequently placed in 10 % ammonium sulphide solution for detection of early implantation loss as described by Sa1ewski.
The liver, kidneys and spleen from each dam were excised, trimmed and weighed and all findings recorded. The carcasses of the dams, including all organs, were then discarded.

Foetal observations: A detailed external examination of each foetus was conducted to include, but was not limited to, the eyes, palate, and external orifices. Findings were recorded as either developmental variations or malformations. The weight and sex of each foetus were recorded and the foetuses were discarded.

Statistical analyses: All analyses were conducted using two-tailed tests for a minimum significance level of 5 % comparing each treated group to the vehicle control group. Each mean was presented with the standard deviation (S.D.) and the number of animals (N) used to calculate the mean. The following statistical tests were performed: Chi-square test with Yates' correction factor (foetal sex ratios); Fisher's Exact test (malformations and variations); Mann-Whitney U test (early and late resorptions, dead foetuses, post-implantation losses); One-way ANOVA with Dunnett's test (corpora lutea, total implantations, viable foetuses, foetal body weights, maternal body weights and weight changes, maternal net body weight changes and gravid uterine weights, selected organ weights).

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS

Dose formulation analysis was not performed in this dose range-finding study
.

B. CLINICAL OBSERVATIONS

All animals survived to the scheduled sacrifice on gestation Day 20. There were no apparent test item-related clinical effects observed in any of the AMPA treated groups. Faeces, which appeared grey in colour, were observed infrequently during the daily examinations at dose levels of 250 mg/kg bw/day and above. The predominant findings at the 1-hour post-dosing period included red staining around the nose, noted in one or two animals in each of the treated groups, and a low incidence of salivation at dose levels of 250 mg/kg bw/day and above. However, no dose-relationship was apparent and the limited incidence of these findings was not considered to be a conclusive indication of a treatment effect.
Other clinical findings (hair loss, soft stool, yellow anogenital, urogenital and proximal tail staining, rales, red staining or material around the vaginal area, nose and mouth, and decreased defaecation and urination) occurred similarly in the control and treated groups or were generally single occurrences.

C. BODY WEIGHT

No adverse effects on mean body weights or mean body weight gains were apparent in any dose group throughout the study. Mean gravid uterine weights and net body weight changes in the treated groups were also apparently unaffected by test item administration. No statistically significant differences were observed between the control group values and those of the AMPA-treated groups.

Table 5.8.1-66: AMPA: DRF teratogenicity study in rats ([redacted], 1991a): Summary of maternal body weight, body weight gain and gravid uterine weight.

	Dose level of AMPA (mg/kg bw/day)					
	0 (control)	125	250	500	750	1000
No. of females	8	8	8	8	8	7
Body weights (g ± SD) Day post coitum						
0	240 ± 16.1	246 ± 11.9	253 ± 13.3	240 ± 9.5	243 ± 20.8	243 ± 11.6
6	266 ± 16.7	269 ± 13.1	278 ± 14.1	265 ± 13.0	270 ± 20.6	269 ± 14.4
12	277 ± 17.1	287 ± 13.9	293 ± 13.8	279 ± 13.1	281 ± 17.8	282 ± 13.1
16	302 ± 23.5	314 ± 17.8	316 ± 16.6	300 ± 13.7	309 ± 23.8	308 ± 16.5
20	365 ± 27.1	377 ± 21.2	379 ± 18.9	359 ± 32.1	374 ± 26.3	349 ± 21.5
Body weight gain (g ± SD) Day 6-16 post coitum	36 ± 8.9	46 ± 11.1	38 ± 8.7	35 ± 11.1	39 ± 7.2	39 ± 4.7
Gravid uterine weight (g ± SD)	73 ± 12.2	78.9 ± 17.1	77.1 ± 8.7	69.8 ± 29.1	77.2 ± 8.2	78.0 ± 3.7

SD = Standard deviation

D. FOOD CONSUMPTION

Food consumption was not recorded in this study.

E. NECROPSY

Gross pathology: At scheduled sacrifice on gestation Day 20, macroscopic necropsy findings were observed as follows. One female at 500 mg/kg bw/day had a pitted kidney while one control group female had a dilated renal pelvis containing white precipitate. The only other remarkable internal finding was an accessory spleen in one female at 250 mg/kg bw/day. These findings were considered not due to treatment.

Organ weights: Mean liver, kidney and spleen weights in the treated groups were similar to the control group, indicating no apparent adverse effect from AMPA administration.

Caesarean section data: The mean numbers and percentages of post-implantation losses and viable

foetuses in the 125, 250, 500, 750 and 1000 mg/kg bw/day groups were similar to the control group. Mean foetal body weights in the treated groups were also comparable to the control group. No remarkable differences were observed between the control and treated groups in foetal sex ratios or the mean numbers of corpora lutea and implantation sites. It was noted that a single female at 1000 mg/kg bw/day was non-gravid; this was considered not due to treatment.

Table 5.8.1-67: AMPA: DRF teratogenicity study in rats ([redacted], 1991a): Intergroup comparison of maternal performance and Caesarean section data

Observation	Dose level of AMPA (mg/kg bw/day)

SD = Standard deviation

F. FOETUSES

There was-no effect of AMPA on the number, growth or survival of the foetuses *in utero*.

The number of foetuses (litters) available for evaluation numbered 112(8), 114(8), 115(8), 107(7), 114(8) and 102(7) in the control, 125, 250, 500, 750 and 1000 mg/kg bw/day groups, respectively. No external malformations or developmental variations were noted in this study.

III. CONCLUSIONS

The dose level of 1000 mg AMPA/kg bw/day was the no observed effect level in this study for both maternal and developmental effects. Based on the results of this study, dose levels of 150, 400 and 1000 mg/kg bw/day were considered suitable for the subsequent definitive developmental toxicity study of AMPA in rats.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This dose range-finding study is considered acceptable. Treatment with AMPA at dose levels of up to 1000 mg/kg bw/day produced no evidence of toxicity in either the dam or on any embryo-fetal development endpoint.

Assessment and conclusion by RMS:

1. Information on the study

Data point	CA 5.8.1/030
Report author	[redacted]

Report year	1991
Report title	A developmental toxicity study of AMPA in rats

Document No	M-645464-01-1
Guidelines followed in study	US EPA Pesticide Assessment Guidelines Subdivision F, 83-3; JMAFF 59 NohSan No. 4200, OECD 414 (1981)
Deviations from current test guideline (OECD 414, 2018)	Duration of treatment was shorter than required. The following endpoints were not assessed: weight and histopathological changes of the maternal thyroid glands, foetal anogenital distance (AGD), indication of incomplete testicular descent/cryptorchidism in male foetuses; assessment of dams' thyroid hormones (T4, T3 and TSH)
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 3a

2. Full summary

Executive summary

The potential maternal toxicity and developmental toxicity of AMPA were evaluated in this study. AMPA in corn oil was administered orally by gavage to three groups of 25 mated Charles River Crl: CD BR female rats once daily from gestation days 6 through 15. Dose levels were 150, 400 and 1000 mg/kg bw/day administered in a constant volume of 10 mL/kg bw. A concurrent control group, composed of 25 mated females, received the vehicle on a comparable regimen at 10 mL/kg bw. Throughout gestation all females were observed twice daily for appearance and behaviour. Body weights and food consumption were recorded at appropriate intervals. On day 20 of gestation, all females were sacrificed for a scheduled Caesarean section. The liver, kidneys and spleen of each female were weighed. The uteri and ovaries were examined and the numbers of foetuses, early and late resorption, total implantations and corpora lutea were recorded. Mean gravid uterine weights and net body weight changes were calculated for each group. Foetuses were weighed, sexed and examined for external, skeletal and soft tissue malformations and developmental variations.

Maternal survival was unaffected by treatment at all dose levels. No treatment-related gross necropsy findings were observed. Clinical findings which appeared related to test item administration occurred at 400 and 1000 mg/kg bw/day and included mucoid faeces, hair loss and soft stool. Mean body weight gains at 1000 mg/kg bw/day were similar to the control group during the initial six days of dosing (gestation Days 6-9 and 9-12); food consumption in this group was slightly decreased compared to the control group during the initial three days of dosing and was slightly increased during gestation Days 9-12. During gestation Days 12-16, mean body weight gain at 1000 mg/kg bw/day was slightly reduced and food consumption was similar to the control group during this interval. Body weight gain and food consumption values at 150 and 400 mg/kg bw/day were comparable to the respective control values. Mean gravid uterine weights, net body weights and net body weight gains, and mean liver, kidney and spleen weights in the AMPA treated groups were similar to the values in the control group. The mean foetal body weight at 1000 mg/kg bw/day group was slightly decreased. No other indication of a developmental effect was apparent at any dose level. No foetal malformations or developmental variations which could be related to treatment were observed at any dose level.

In conclusion, a marginal degree of maternal toxicity and a marginal degree of developmental toxicity were observed at 1000 mg/kg bw/day; maternal body weight gain and food consumption values were slightly less than those in the control group for a short duration and mean foetal body weight was slightly decreased. Clinical findings (mucoid faeces, soft stool and hair loss) were the only maternal response at

400 mg/kg/day.

B. STUDY DESIGN AND METHODS

In-life dates: 07 Aug 1990 – 31 Aug 1990

Mating procedure: At the end of the acclimatization period, animals judged to be in good health and meeting acceptable body weight requirements (a minimum of 220 grams) were placed in a suspended wire-mesh cage with a resident male from the same strain and source for breeding. Resident males were untreated, sexually mature rats utilized exclusively for breeding. A breeding record containing the male and female identification numbers and the dates of cohabitation was prepared. The females were approximately 12 weeks old when paired for breeding.
Positive evidence of mating was confirmed by the presence of a copulatory plug in the vagina or the presence of sperm in a vaginal smear. Each mating pair was examined daily. The day on which evidence of mating was identified was termed Day 0 of gestation and the animals were separated.

Animal assignment: The mated females were consecutively assigned in a block design to groups containing eight rats each by the following randomization procedure. The first mated female and the appropriate gestation Day 0 designation were entered on the form and the female was assigned to group 1, the second mated female was assigned to group 2, and the third to group 3, etc. This process was continued daily until eight females were placed into each group. Body weight values ranged from 213 g to 261 g on Day 0 of gestation.

Dose preparation and analysis: An appropriate amount of the test item (AMPA) was weighed for each group into tared weigh boats and transferred to a mortar. The test material was triturated with corn oil, and ground with a pestle until a slurry was obtained. The slurry was transferred to a graduated cylinder via a series of vehicle rinses. A sufficient amount of vehicle was added to attain a volume of 800 mL. The cylinder was inverted several times to ensure adequate mixing and the contents were transferred to a

properly labelled storage container. The cylinder was rinsed with an additional 620 mL of vehicle, which was also added to the storage container. The preparations were then mixed for approximately 5 minutes on a Polytron PT6000 homogenizer to reduce particle size and to ensure proper mixing. The dosing preparations were visually inspected for homogeneity prior to dispensation for the first day of dose administration.
Preparations for all dose groups were made once at study start, and were stored at room temperature. A second preparation for the 150 mg/kg bw/day group was made one week later, and stored at room temperature. The preparations were stirred using a magnetic stir plate and bar each day prior to dispensing and during the dosing procedure.
Samples of the test material preparations were analysed at the Monsanto Company. The following aliquots were drawn on the first day of dose formulation: one sample (middle) from the control group (group 1) and two samples (top and bottom) from the mid-dose group (group 3) preparations to verify concentration; and three samples (top, middle, bottom) from the low dose group (group 2) and high dose group (group 4) preparations to verify concentration and homogeneity. One week later, three aliquots (top, middle and bottom) were taken from the low dose group preparation. In the last week of dosing, two aliquots (top and bottom) were taken from the low dose and high dose group preparations. For all dates, samples at room temperature were sent to the sponsor for analysis. The analytical results were reported separately (see CA 4). AMPA concentrations in corn oil dosing solutions were found to be 105 - 120 % of the target levels.

Dose administration: The dose formulations were administered orally by gavage, via a 16-gauge stainless steel gavage cannula, once daily for 10 consecutive days initiating on gestation Day 6 and continuing up to and including Day 15 of gestation. A dosage volume of 10 mL/kg bw was used for all dose levels. The control animals received corn oil on a comparable regimen of 10 mL/kg bw. Individual dosages were based on the most recent body weights.

Clinical observations: All animals were observed twice daily for moribundity and mortality. Detailed clinical observations were recorded individually from Days 0 through 20 of gestation (prior to compound administration during the dosing period). Animals were observed for signs of toxicity approximately one hour after treatment throughout the dosing period; only significant findings were recorded at the post-dosing observation period.

Bodyweight and gravid uterine weight: Maternal body weights were recorded individually on gestation Days 0, 6, 9, 12, 16 and 20. A group mean body weight was calculated for each of these days. Mean body weight changes were calculated for each corresponding interval and also for Days 6-16 and 0-20.
Gravid uterine weight, net body weight (the Day 20 body weight minus the weight of the uterus and contents) and net body weight change (the Day 0-20 body weight change minus the weight of the uterus and contents) were presented for each gravid female at the scheduled Caesarean section.

Food consumption: Individual food consumption was recorded on Days 0, 6, 9, 12, 16 and 20 of gestation. Food intake was calculated as g/animal/day and g/kg bw/day for the corresponding body weight change intervals. On the occasions when food intake could not be measured for one of the days in a given interval, food intake was calculated using the appropriate number of days for that interval.

Terminal investigations: All maternal animals were sacrificed by carbon dioxide inhalation on gestation Day 20. The thoracic, abdominal and pelvic cavities were opened by a ventral midline incision and the contents examined. In all instances, the post mortem findings were correlated with the ante mortem comments and any abnormalities were recorded. The uterus and ovaries were excised. The number of corpora lutea on each ovary was recorded. The trimmed uterus was weighed, opened and the number and location of all foetuses, early and late resorptions and the total number of implantation sites were recorded. Uteri with no macroscopic evidence of nidation were opened and subsequently placed in 10 % ammonium sulphide solution for detection of early implantation loss as described by Sa1ewski.
The liver, kidneys and spleen from each dam were excised, trimmed and weighed and all findings recorded. The carcasses of the dams, including all organs, were then discarded.

Foetal observations: Each foetus was individually sexed, weighed and tagged for identification. A detailed external examination of each foetus was conducted to include, but was not limited to, the eyes, palate, and external orifices and each finding was recorded. Crown-rump measurements were recorded for late resorptions and the tissues were discarded. The sex of each foetus was verified by an internal examination. Each foetus was examined viscerally by a modification of the Stuckhardt and Poppe fresh dissection technique to include the heart and major vessels. Foetal kidneys were examined and graded for renal papillae development by a method described by Woo and Hoar.
Heads from approximately one-half of the foetuses from each female were placed in Bouin's fixative for subsequent soft-tissue examination by the Wilson sectioning technique. The heads from the remaining one-half of the foetuses were examined by a mid-coronal slice. All carcasses were eviscerated and fixed in 95 % isopropyl alcohol. Following fixation in alcohol, each foetus was macerated in potassium hydroxide and stained with Alizarin Red S by a method similar to that described by Dawson. The skeletal examination was conducted utilizing low power magnification provided by a stereomicroscope. External, visceral and skeletal findings were recorded as developmental variations or malformations. The foetal developmental findings were summarized by 1) presenting the incidence of a given finding both as a percentage of the no. of foetuses and the no. of litters available for examination in the group and 2) by considering the litter as the basic unit for comparison and calculating the number of affected foetuses in a litter on a proportional basis.

Statistical analyses: All analyses were conducted using two-tailed tests for a minimum significance level of 5 % comparing each treated group to the vehicle control group. Each mean was presented with the standard deviation (SD) and the number of animals (N) used to calculate the mean. The following statistical tests were performed: Chi-square test with Yates' correction factor (foetal sex ratios); Fisher's Exact test (malformations and variations); Mann-Whitney U test (early and late resorptions, dead foetuses, post-implantation losses); One-way ANOVA with Dunnett's test (corpora lutea, total implantations, viable foetuses, foetal body weights, maternal body weights and weight changes, maternal net body weight changes and gravid uterine weights, selected organ weights); Kruskal-Wallis test (litter proportions of intrauterine data, considering the litter rather than the foetus as the experimental unit).

II. RESULTS AND DISCUSSION

A: ANALYSIS OF DOSE FORMULATIONS

The analytical results were reported separately by the Monsanto Company. AMPA concentrations in corn oil dosing solutions were found to be 105 - 120 % of the target levels.

B: CLINICAL OBSERVATIONS

All animals survived to the scheduled sacrifice on gestation Day 20. The predominant clinical findings observed during the study were mucoid faeces, hair loss and soft stool. Mucoid faeces occurred only in the AMPA treated groups and with very few exceptions, occurred only during the dosing period with an occasional incidence following the dosing period. The incidence of mucoid faeces was increased by numerical progression in the 400 and 1000 mg/kg bw/day groups; the incidence of mucoid faeces in the 150 mg/kg nbw/day group was limited to three consecutive days for a single animal.
Hair loss on various body surfaces (primarily the forelimbs, hindlimbs and lateral abdominal area) and soft stool occurred similarly in the control group and the 150 mg/kg/day group, however, the incidence of each finding was slightly increased and appeared treatment-related in the 400 and 1000 mg/kg bw/day groups.
In some cases, hair loss on the forelimbs was initially noted prior to the treatment period. Hair loss on the hindlimbs and lateral abdominal area was first observed after dosing initiated. Once observed, hair loss generally persisted throughout the treatment and post-treatment periods.
Soft stool generally occurred during the treatment period with an occasional incidence following the treatment period. Other clinical findings observed during the study were infrequent in occurrence or occurred similarly in the control group. No clinical findings were observed at the l-hour post-dosing observation period.

Table 5.8.1-68: AMPA: Teratogenicity study in rats ([redacted], 1991b): Summary of selected clinical findings.

	Dose level of AMPA (mg/kg bw/day)

Mucoid faeces	0	1	7	18

C. BODY WEIGHT

Mean body weight gains at 1000 mg/kg bw/day were similar to the control group during the initial six days of the dosing period (gestation Days 6-9 and 9-12). During gestation Days 12-16, mean body weight gain at 1000 mg/kg bw/day was slightly reduced (statistically significant at $p<0.01$) compared to the control group. Mean body weight gains at 1000 mg/kg bw/day were similar to the control group when evaluated over the entire treatment period (gestation Days 6-16) and the post-treatment period (gestation Days 16-20). Mean absolute body weight values at 1000 mg/kg bw/day were comparable to the control group throughout the study. No adverse effects on mean body weights and mean body weight gains were observed at 150 and 400 mg/kg bw/day during the study.

Mean gravid uterine weights, net body weight gains and net body weights in the AMPA treated groups were similar to the control group.

Table 5.8.1-69: AMPA: Teratogenicity study in rats ([redacted], 1991b): Summary of gravid female body weight, body weight gain and gravid uterine weight.

	Dose level of AMPA (mg/kg bw/day)

SD = Standard deviation
** significantly different from control p<0.01 (Dunnett's test, two-tailed)

D. FOOD CONSUMPTION

Food consumption (evaluated as g/animal/day and g/kg bw/day) at 1000 mg/kg bw/day was slightly decreased compared to the control group during the initial three days of dosing (gestation Days 6-9); this was statistically significant (p<0.05) when evaluated as g/kg bw/day. During gestation Days 9-12, food intake (g/animal/day and g/kg bw/day) at 1000 mg/kg bw/day was slightly increased (p<0.05) when compared to the control group. Food consumption at1000 mg/kg bw/day was similar to the control group for the remainder of the treatment period (gestation Days 12-16), the entire treatment interval (gestation Days 6-16), and the post-treatment period (gestation Days 16-20).
Food consumption, evaluated as g/animal/day and g/kg bw/day, was apparently unaffected by treatment at dose levels of 150 and 400 mg/kg bw/day. The only statistically significant differences were in the 400 mg/kg bw/day group; food consumption values were slightly increased (g/animal/day and g/kg bw/day) during gestation Days 12-16, 6-16, and 0-20 (p<0.05).

Table 5.8.1-70: AMPA: Teratogenicity study in rats ([redacted], 1991b): Summary of gravid female consumption.

	Dose level of AMPA (mg/kg bw/day)			
	0 (control)	**150**	**400**	**1000**

SD = Standard deviation
* significantly different from control p<0.05 (Dunnett's test, two-tailed)

E. NECROPSY

Gross pathology: At scheduled sacrifice on gestation day 20, no treatment-related gross necropsy findings were observed. Dilated renal pelves were observed in 2, 3 and 1 animal(s) in the control, 150 and 1000 mg/kg bw/day groups, respectively. A single animal in the control group had a white area on the spleen. There were no other macroscopic findings.

Organ weights: Mean liver, kidney and spleen weights in the treated groups were similar to the control group, indicating no apparent adverse effect from AMPA administration.

Caesarean section data:
No adverse effects were observed at any dose level on post-implantation loss, the numbers of viable foetuses, or foetal sex ratios. All values in the 150, 400 and 1000 mg/kg bw/day groups were comparable to the control group when evaluated on a group mean or proportional (%) litter basis. The mean numbers of corpora lutea and implantation sites in the AMPA treated groups were similar to the corresponding control group values.

Table 5.8.1-71: AMPA: Teratogenicity study in rats ([redacted], 1991 b): Intergroup comparison of maternal performance and Caesarean section data

Observation	Dose level of AMPA (mg/kg bw/day)			
	0 (control)	150	400	1000
No. of animals mated	25	25	25	25

SD = Standard deviation
* significantly different from control p<0.05 (Dunnett's test, two-tailed)

F. FOETUSES

Mean foetal body weight at 1000 mg/kg bw/day was slightly and statistically significantly (p<0.05) decreased (3.3 g) when compared to the control group (3.5 g). This reduction was mainly attributable to two litters with mean foetal body weights of 2.4 g and 2.8 g, respectively. Mean foetal body weight at 1000 mg/kg bw/day was similar to the minimum value in the laboratory historical control data (3.3 g). A mean foetal body weight of 3.3 g has been observed in five of 85 (6 %) of the studies in the laboratory historical control data. At 150 and 400 mg/kg bw/day, mean foetal body weights were either identical to or were similar to the control group (3.5 g and 3.4 g, respectively). A mean foetal body weight of 3.4 g has been observed in 20 of 85 studies (24 %) in the laboratory historical control data set.

There was-no effect of AMPA on the number or survival of foetuses.
The numbers of foetuses (litters) available for morphological evaluation were 345 (24), 347 (24), 346 (24) and 349 (24) in the control, 150, 400 and 1000 mg/kg bw/day groups, respectively. The number of foetuses (litters) with malformations were 2 (2), 4 (4), 0 (0) and 2 (2) in these same dose groups, respectively.

External examination: External malformations were observed in the control, 150 and 1000 mg/kg bw/day groups. One foetus in the control group had microphthalmia (unilateral). At 150 mg/kg bw/day, one dam had dizygotic conceptuses. It was observed that the umbilical structures of the resorbed foetus were reduced and conjoined with the umbilical cord of the surviving foetus, and the resorbed foetus was enclosed in a sac. At the subsequent visceral and skeletal examinations, it was noted that this viable conceptus had a soft tissue malformation and variation (an interrupted aortic arch and a distended ureter, respectively) and a skeletal malformation (a vertebral anomaly without an associated rib anomaly). Detailed descriptions of these soft tissue and skeletal anomalies are presented in the table below. At 1000 mg/kg bw/day, two anomalies were observed: one foetus had localized oedema in the neck and thoracic regions, and another foetus had sternoschisis. No external developmental variations were observed at any dose level

Visceral examination: Soft tissue malformations were observed only in the control and the 150 mg/kg bw/day group. One foetus in the control group had hydrocephaly. At 150 mg/kg bw/day, one foetus had situs inversus. A viable dizygotic conceptus at 150 mg/kg/day had a soft tissue malformation and variation (an interrupted aortic arch and distended ureter, respectively) which were already described in the context of the external examination. Soft tissue variations were also observed in single foetuses in the control and the 400 mg/kg bw/day group. In the control group, one foetus had distended ureters. At 400 mg/kg bw/day, one foetus had a haemorrhagic ring around the iris. No other soft tissue malformations or variations were observed.

Skeletal examination: The only skeletal malformations were observed at 150 mg/kg bw/day group. A viable dizygotic conceptus had a skeletal anomaly (a vertebral anomaly without an associated rib anomaly, which was described in the context of the external examination. A single foetus had hemispherical enlargement of rib no. 3. Another foetus had a bent radius (bilateral) and a vertebral anomaly with an associated rib anomaly (left thoracic arch no. 11 and half of the centrum were absent; thoracic centrum no. 10 was malpositioned; and left rib nos. 10 and 11 were fused proximally). Several skeletal variations were observed in the control and treated groups. The most notable variants were sternebra(e) nos. 5 and/or 6 unossified, 14th rudimentary ribs, reduced ossification of the 13th ribs, and 7th cervical ribs; these are commonly observed variants in the laboratory historical control data. No dose-relationship was apparent in the percentage of foetuses (litters) affected in the dose groups and the variations occurred with a similar frequency in the control group. Also, the skeletal variants were well within the ranges observed in the laboratory historical control data. Other variants observed were infrequent occurrences or occurred similarly in the control group.

Summary of foetal examinations: Considering both the incidence and the expression of specific anomalies, the external, soft tissue and skeletal malformations observed in the treated groups appeared to be spontaneous in origin (2, 4, 0 and 2 foetuses in the control, 150, 400 and 1000 mg/kg bw/day groups had malformations). Also the skeletal variants which were observed in the study occurred with a similar frequency in the control group

Table 5.8.1-72: AMPA: Teratogenicity study in rats ([redacted], 1991b): Group incidence of foetal malformations

Observation	Dose level of AMPA (mg/kg bw/day)

III. CONCLUSIONS

A marginal degree of maternal toxicity and a marginal degree of developmental toxicity were noted at 1000 mg/kg bw/day as clinical signs, transient reductions of maternal body weight gain and food consumption. Similar clinical findings were the only maternal response at 400 mg/kg bw/day. With this exception, the NOAEL (no observable adverse effect level) for maternal toxicity and developmental toxicity was considered to be 400 mg/kg bw/day.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This developmental toxicity study is considered acceptable, although some endpoints that are requested in the OECD 414 TG from 2018 are not included in this study. At 1000 mg/kg bw/day, a marginal degree of maternal and developmental toxicity was noted in form of clinical signs, transient reductions in body weight gain, food consumption and reduced foetal body weights. Clinical signs (alopecia and mucoid faeces) were also noted at 400 mg/kg bw/day. Accordingly, the NOAEL for maternal toxicity was considered to be 150 mg/kg bw/day, while the NOAEL for developmental toxicity was considered to be 400 mg/kg bw/day.

Assessment and conclusion by RMS:

Literature

A literature search for the active substance glyphosate was performed in accordance to the provisions of the EFSA Guidance "Submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) 1107/2009" and updated Appendix to this Guidance document. The following publications were found relevant and reliable for this section and the summaries are thus presented below and are part of the general discussion at the beginning of the section.

Table 5.8.1-73: Overview on literature found relevant for evaluation of glyphosate in section 5.8.1

Annex Point	Study	Study type Parameters investigated Test system	Substance Dose levels Exposure	Reliability and relevance comments	Result
CA 5.8.1/031	Kwiatkowska M. *et al.*, 2020	Apoptosis induction in human peripheral blood mononuclear cells	AMPA, Purity: 98 % 0.01 to 5 mM	Reliable with restriction No cytotoxicity tests performed to establish appropriate doses Most effects above physiological ranges, > 1mM Glyphosate impurities tested at unrealistically high concentrations No positive controls to verify assay viability	Low apoptotic potential. Borderline high dose effects.

1. Information on the study

Data point:	CA 5.8.1/031
Report author	Kwiatkowska, M. *et al.*
Report year	2020
Report title	Evaluation of apoptotic potential of glyphosate metabolites and impurities in human peripheral blood mononuclear cells (*in vitro* study)
Document No	doi.org/10.1016/j fct.2019.110888 E-ISSN: 1873-6351
Guidelines followed in study	None
Deviations from current test guideline	Not applicable
Previous evaluation	None
GLP/Officially recognised testing facilities	No, not conducted under GLP/Officially recognised testing facilities (Research conducted in an academic laboratory)
Acceptability/Reliability:	Yes/Reliable with restrictions

2. Full summary of the study according to OECD format

The study aimed to assess the effect of glyphosate, its metabolites: aminomethylphosphonic acid (AMPA), methylphosphonic acid and its impurities: PMIDA, N-methylglyphosate, hydroxymethylphosphonic acid and bis (phosphonomethyl)amine on apoptosis induction in human peripheral blood mononuclear cells (PBMCs). PBMCs were exposed to the compounds studied at concentrations ranging from 0.01 to 5 mM for 4 h. It was observed an increase in reactive oxygen species (including hydroxyl radical) and cytosolic

calcium ions levels as well as reduction of transmembrane mitochondrial potential (ΔΨm) in PBMCs exposed to the compounds examined. All substances studied changed PBMCs membrane permeability, activated caspase-8, -9, -3 and caused chromatin condensation, which showed that they were capable of inducing apoptosis both via extrinsic and particularly intrinsic pathway. Generally the study demonstrated that there were no differences between apoptotic changes induced by glyphosate, its metabolites or impurities, and observed changes were provoked by high concentrations of investigated compounds. Since clear changes were only seen at high concentrations, a low apoptotic potential of these compounds was concluded.

I. MATERIALS AND METHODS

Chemicals; The investigated compounds i.e., aminomethylphosphonic acid (AMPA) (purity 98 %), methylphosphonic acid (purity 98 %), N-(phosphonomethyl)iminodiacetic acid (PMIDA) (purity 98 %), N-methylglyphosate, hydroxymethylphosphonic acid (purity 98 %) and bis-(phosphonomethyl)amine (purity 97 %) were synthetized by the Institute of Industrial Organic Chemistry, Warsaw, Poland. Glyphosate [N-(phosphonomethyl)glycine] (purity 95 %) in acid form was bought from Sigma-Aldrich, USA. The investigated compounds were dissolved in phosphate-buffered saline (pH 7.4). Other chemicals were purchased from POCh (Poland) and Roth (Germany) and were of analytical grade. Different concentrations of glyphosate have been selected in this study:

- 0.01 mM (low concentration) that is quite similar to the concentration determined in blood of humans who were not directly exposed to this herbicide,
- 0.05 mM to 0.5 mM (moderate to high concentration) that corresponds to the concentration that may penetrate into human blood as a result of glyphosate formulation poisoning,
- 5 mM to 10 mM (very high concentration) that corresponds to the concentration detected in humans after acute poisoning with glyphosate formulation.

Cells isolation; PBMCs were isolated from leucocyte-buffy coat obtained from blood collected in Blood Bank in Lodz, Poland. Blood was taken from healthy, non-smoking volunteers who showed no signs of infection disease symptoms at the time the blood samples were collected. The study was approved by the Bioethics Committee of the University of Lodz No. KBBN-UŁ/I/3/2013. The final PBMCs density used in the experiments (after addition of glyphosate, its metabolites or impurities) was $2x10^6$ per 1 mL. The viability of the cells was over 95 % as determined by flow cytometry.

Quantitative determination of apoptosis (YO-PRO-1/PI staining); Apoptosis is characterized by changes in cell membrane permeability. Apoptotic cells that have altered membrane permeability (membrane integrity is maintained) are permeable for a marker YOPRO-1 (carbocyanine nucleic acid stain), which exhibits green fluorescence, whereas they are not permeable for the dye propidium iodide (PI) that shows red fluorescence. The cells were treated with glyphosate, its metabolites and impurities in the final concentrations ranging from 0.01 to 10 mM and incubated for 4 h at 37 °C in total darkness. Apoptosis was induced with 10 µM of camptothecin. After the incubation, the samples were centrifuged at 300 g for 5 min at 4 °C, the supernatant was removed, and the cells were supplemented with RPMI with L-glutamine and 10 % FBS. Then, the mixture of YO-PRO-1 and PI (0.1 µM each) was added to the samples, which were incubated for 20 min on ice in total darkness. The samples were analysed by flow cytometry (LSR II, Becton Dickinson) with excitation maximum at 488 nm to visualize the YO-PRO-1 green fluorescence (520/30 bandpass filter) and PI red fluorescence (610/20 bandpass filter). FMC gate on PBMCs has been established for data acquisition and the data were recorded for a total of 10,000 events per sample.

Determination of biochemical and morphological hallmarks of apoptosis

Cytosolic calcium ion level; Calcium ion accumulated in mitochondria and endoplasmatic reticulum is an important secondary messenger in controlling apoptotic cell death. The level of cytosolic calcium ions was analysed by flow cytometry (LSR II, Becton Dickinson) using a fluorescent probe Fluo-3/AM according to manufacturer's protocol. Fluo-3/AM passes through membrane of living cells, in which it is cleavaged by intracellular esterases to Fluo-3. Inside the cell, Fluo-3 exhibits green fluorescence after complexation with calcium ions. PBMCs treated with glyphosate, its metabolites or impurities in the final concentrations ranging from 0.01 to 10 mM were incubated for 4 h at 37 °C in total darkness. Next, the cells were centrifuged at 300 g for 5 min at 4 °C, suspended in Fluo-3/AM (1 µM) solution and incubated at 37 °C for

20 min in total darkness. Then, Hanks' Balanced Salt Solution (HBSS), composed of inorganic salts and supplemented with glucose (with 1 % of BSA) was added to the cells suspension, and PBMCs were incubated for 40 min at 37 °C in total darkness. The cells were centrifuged at 300 g for 5 min at 4 °C and washed twice with HEPES buffer. After centrifugation, PBMCs were suspended in HEPES buffer and incubated for 10 min at 37 °C in total darkness. The samples were analysed using flow cytometer (LSR II, Becton Dickinson) with excitation at 490/500 nm to visualize the Fluo-3 fluorescence. FMC gate on PBMCs has been established for data acquisition and the data was recorded for a total of 10,000 events per sample.

Mitochondrial transmembrane potential (ΔΨm); Mitochondrial dysfunction leading to collapse of transmembrane mitochondrial potential has been shown to participate in the induction of apoptosis. Transmembrane mitochondrial potential was shown as red fluorescence intensity of MitoTracker Red CMXRos (excitation/emission maxima – 579/599 nm). This probe is cell permeable and contains mildly thiol-reactive chloromethyl moiety for mitochondrial labeling. Nigericin and valinomycin (1 μM) were used to increase and decrease ΔΨm, respectively. PBMCs were exposed to glyphosate, its metabolites or impurities for 4 h at 37 °C in total darkness. Then, the samples were centrifuged at 300 g for 5 min at 4 °C, the supernatant was decanted, and the cells were suspended in PBS. The cells were stained with MitoTracker CMXRos in the final concentration of 1 μM for 15 min at 37 °C in total darkness, and then analysed in 96-well plates using a microplate reader (Cary Eclipse, Varian).

Caspase-8, -9 and -3 activity; Caspases are critical enzymes of apoptosis. The caspases are able to break down peptide bonds via cysteine residues in various substrates, and therefore they catalyze the apoptotic cell death irreversibly in mammals including human beings. Analysis of caspase-8 and -3 was executed according to the manufacturer's protocols. The assays were based on the hydrolysis of the peptide substrates such as acetyl-Ile-Glu-Thr-Asp-7-amino-4-methylcoumarin (Ac-IETDAMC) by caspase-8 and acetyl-Asp-Glu-Val-Asp-7-amino-4-methylcoumarin (Ac-DEVD-AMC) by caspase-3, which resulted in the release of the fluorescent 7-amino-4-methylcoumarin (AMC). The excitation and emission wavelengths of AMC were 360 nm and 460 nm, respectively. Caspase-9 colorimetric assay was based on hydrolysis of the substrate acetyl-Leu-Glu-His-Asp-p-nitroaniline (Ac-LEHD-pNA), which led to the release of p-nitroaniline (pNA) that absorbance was determined at 405 nm. Camptothecin (10 μM) was used to induce apoptosis. Detection of caspase-3 and -8 activities was executed using fluorescent microplate reader (Fluoroskan Ascent FL, Labsystem) and determination of caspase-9 activity was performed using absorbance microplate reader (BioTek ELx808, Bio-Tek).

Hoechst 33342/PI staining; Chromatin condensation paralleled by DNA fragmentation is one of the most important criteria, which are used to identify apoptotic cells. Morphological changes of chromatin in PBMCs were assessed by double staining with Hoechst 33342 and PI. The cells were exposed to glyphosate, its metabolites or impurities for 4 h at 37 °C in total darkness. After incubation, PBMCs were centrifuged at 200 g for 3 min at 4 °C. The supernatant was removed, and the cells were suspended in PBS (0.5 ml). Then the mixture of 1 μl of Hoechst 33342 and 1 μl of PI (1 mg/ml each) was added. After 1 min incubation at 37 °C in total darkness, the cells were analysed by fluorescence microscope (Olympus IX70, Japan) at 400x magnification. PMBCs were classified on the basis of their morphological staining characteristics: viable (blue fluorescence), early apoptotic (intensive bright blue fluorescence), late apoptotic (blue-violet fluorescence) and necrotic (red fluorescence).

Determination of reactive oxygen species level

Oxidation of 6-carboxy-2′,7′-dichlorodihydrofluorescein diacetate; ROS play a central role in regulation of the main pathways of apoptosis mediated by mitochondria, death receptors and the endoplasmic reticulum (ER). The rate of 6-carboxy-2′,7′-dichlorodihydrofluorescein diacetate (H2DCF-DA) oxidation was assessed by flow cytometry. 6-CarboxyH2DCF-DA is a compound widely used for the detection of intracellular oxidants production. The probe diffuses across cellular membrane where it is hydrolyzed by intracellular esterases to 6-carboxy-2′,7'dichlorodihydrofluorescein (6-carboxy-H2DCF) that after oxidation, yields highly fluorescent 6-carboxy-2′,7′-dichlorofluorescein (DCF). The cells were treated with glyphosate, its metabolites or impurities for 4 h at 37 °C in total darkness. Next, fluorescent marker was added to PBMCs, which were stained for 15 min at 37 °C in the dark. The final concentration of the fluorescent probe was 10 μM. Positive control consisted of hydrogen peroxide (2 mM). FMC gate on PBMCs has been established for data acquisition, and fluorescence was measured with the excitation and emission maxima of 488 and 530 nm, respectively. The data was recorded for a total 10,000 events per

sample.
Oxidation of hydroxyphenyl fluorosceine; Highly reactive oxygen species (mainly hydroxyl radical) were assessed using flow cytometer (Becton Dickinson, LSR II) and 3-(p-hydroxyphenyl)-fluorescein (HPF). HPF is nonfluorescent until it reacts with hydroxyl radical. As a result of oxidation, the probe exhibits bright green fluorescence (excitation/emission maxima – 490/515 nm). Formation of hydroxyl radical was provoked by the addition of the mixture of ferrous perchlorate(II) (0.1 mM) and hydrogen peroxide (1 mM) to PBMCs suspension. Finally, the cells were treated with HPF in the final concentration of 2 µM and incubated for 15 min at 37 °C in total darkness. The data was recorded for a total of 10,000 events per sample.
Statistical analysis; The statistical analysis was performed with STATISTICA 8 data analysis software (2000 StatSoft, Inc., Tulsa, OK, USA). In this study, one-way analysis of variance (ANOVA) (p and F added to the description of the results) with post hoc multiple comparisons procedure (Tukey test) was used to assess statistical differences in case of normal distribution (significance marked on the charts). The difference was considered to be significant for $P < 0.05$. The individual analysis was performed on blood from 4 to 5 donors, while each experiment was repeated trice.

II. RESULTS

Apoptotic changes; After 4 h incubation, all compounds studied caused an increase in the number of apoptotic cells. Apoptotic changes were observed in PBMCs treated with 0.5 mM and 5 mM of glyphosate, PMIDA and hydroxymethylphosphonic acid. Two glyphosate metabolites: AMPA and methylphosphonic acid as well as two glyphosate impurities: N-methylglyphosate and bis-(phosphonomethyl)amine caused apoptotic changes only at their highest concentration of 5 mM (Fig. 1).

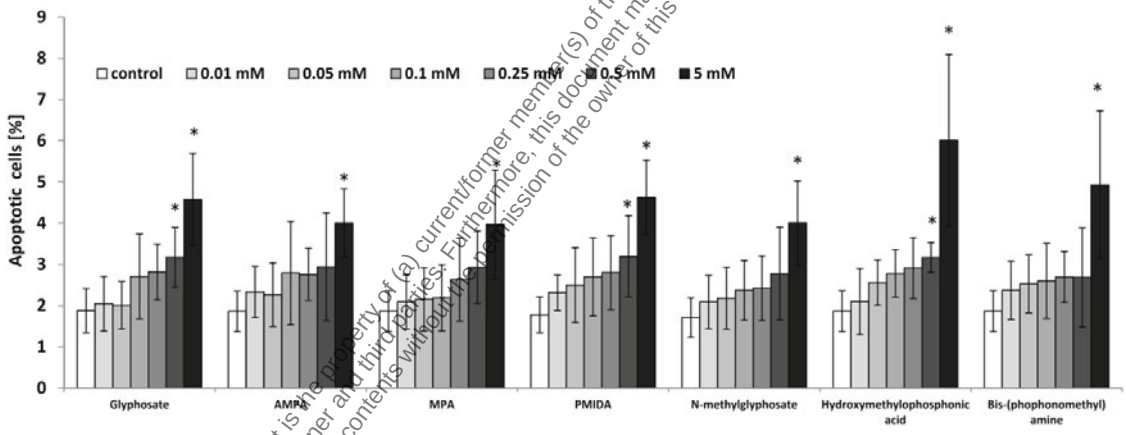

Fig. 1. Changes in the number of apoptotic PBMCs (expressed in per cent) after 4 h incubation with glyphosate, its metabolites and impurities. (*) Statistically significant changes compared to the control ($P < 0.05$).

Morphological changes of chromatin; Cell staining with Hoechst 33342 and PI allowed for the observation of early apoptotic cells (blue color), late apoptotic cells (blue-violet color) and necrotic cells (red color) in the population of PBMCs exposed to the compounds examined for 4 h. Selected photographs showing the presence of individual types of apoptotic and necrotic PMBCs are presented below (Photo 1).

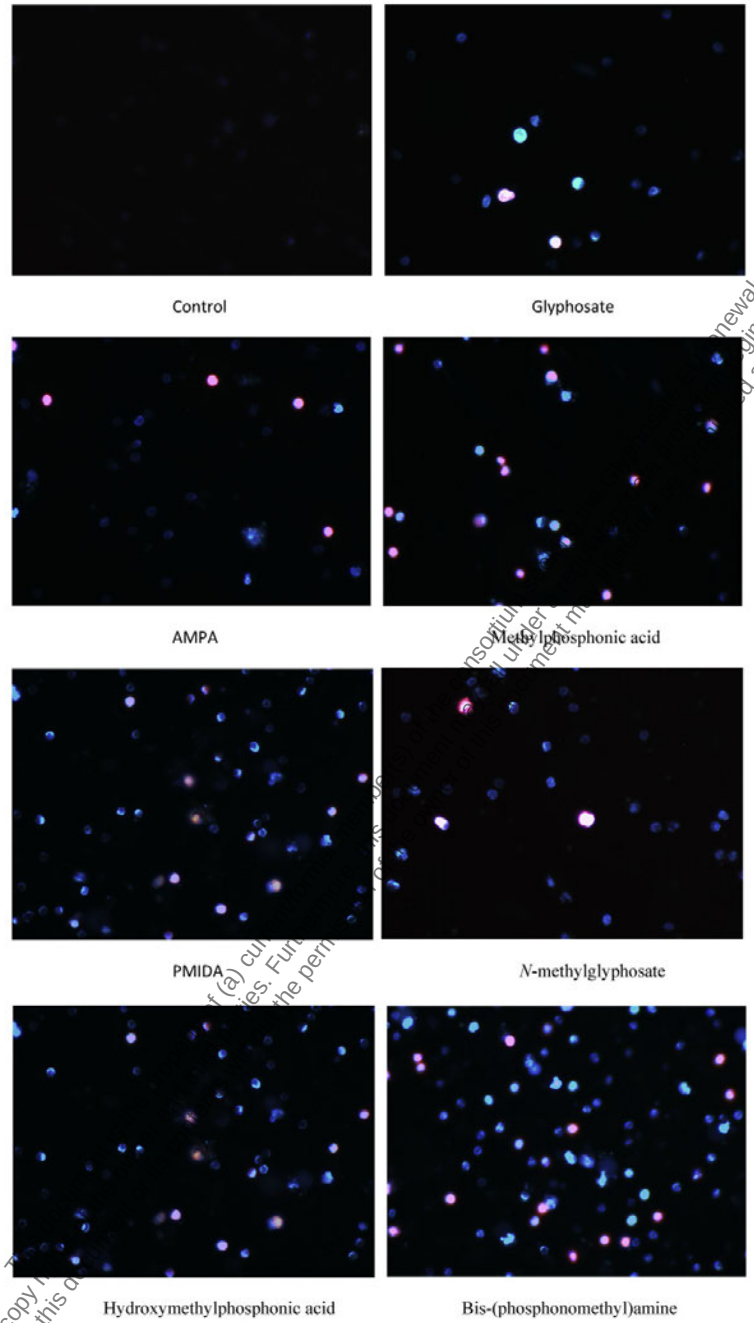

Photo 1. The representative photomicrographs of Hoechst 33324/PI-stained PBMCs pretreated with PBS (control) and with 5 mM of glyphosate, AMPA, methylphosphonic acid, PMIDA, *N*-methylglyphosate, hydroxymethylphosphonic acid and bis-(phosphonomethyl)amine. Viable cells (blue fluorescence), early apoptotic cells (intensive bright blue fluorescence), late apoptotic cells (blue-violet fluorescence) and necrotic cells (red fluorescence).

Cytosolic calcium ion level; A statistically significant increase in cytosolic calcium ion level was observed after incubation of PBMCs with glyphosate and other compounds studied (except for PMIDA). Statistically significant changes were observed for the highest concentration (5 mM) of glyphosate, AMPA and N-methylglyphosate. Glyphosate metabolite - methylphosphonic acid and glyphosate impurity - bis(phosphonomethyl)amine from the concentration of 0.5 mM caused an increase in cytosolic calcium ion level, while hydroxymethylphosphonic acid induced changes in the parameter studied from the concentration of 0.25 mM (Fig. 2).

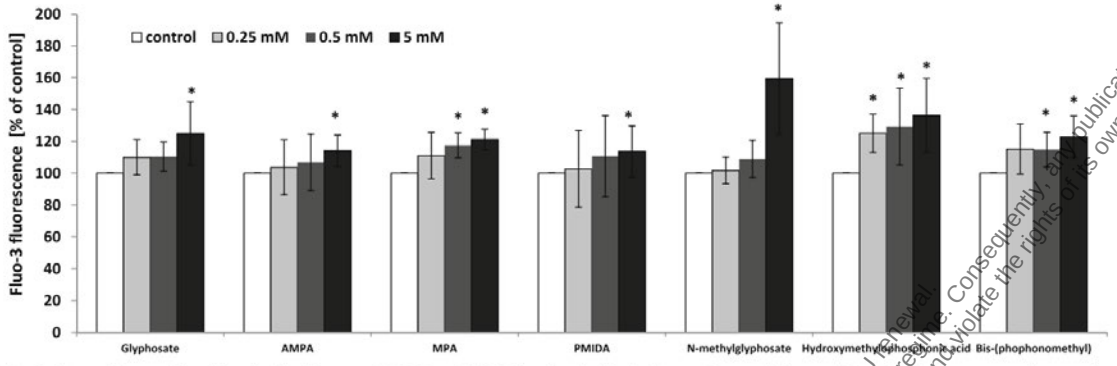

Fig. 2. Changes in cytosolic calcium ion level in control PBMCs and PBMCs incubated with glyphosate, its metabolites and impurities in the concentrations ranging from 0.25 to 5 mM for 4 h (*) Statistically significant changes compared to control ($P < 0.05$).

Transmembrane mitochondrial potential (ΔΨm); Most of the compounds studied caused a decrease in transmembrane mitochondrial potential, while hydroxymethylphosphonic acid (at 0.25 mM) caused statistically significant increase in the parameter examined. Glyphosate and one of its production impurities: bis(phosphonomethyl)amine (from the concentration of 0.05 mM) decreased ΔΨm. Other glyphosate metabolites: AMPA and methylphosphonic acid, and two glyphosate impurities: PMIDA and N-methylglyphosate decreased the parameter studied from the concentration of 0.1 mM (Fig. 3).

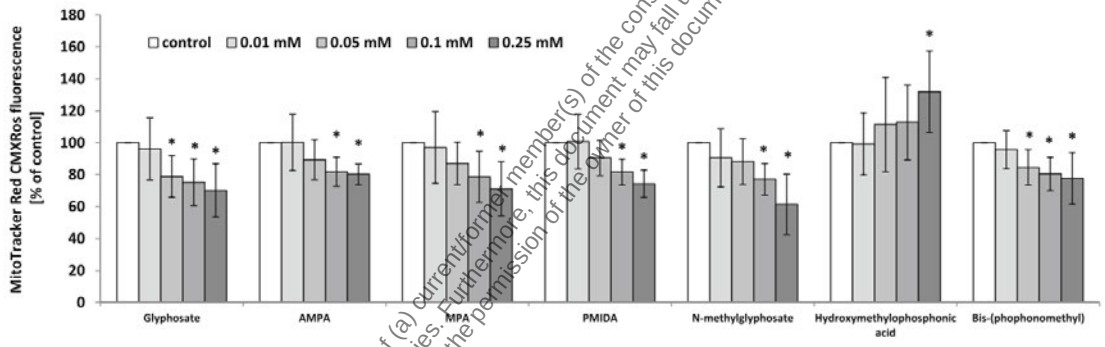

Fig. 3. Changes in transmembrane mitochondrial potential in control PBMCs and PBMCs incubated for 4 h with glyphosate, its metabolites and impurities in the concentrations ranging from 0.01 to 0.25 mM (*) Statistically significant changes compared to control ($P < 0.05$).

Caspase-8 and -9 activity; Glyphosate, AMPA, PMIDA and bis-(phosphonomethyl)amine increased in caspase-8 activity. The changes were observed in PBMCs treated with 0.5 mM of glyphosate and AMPA and with the highest concentration (5 mM) of PMIDA and bis-(phosphonomethyl)amine. Other compounds studied such as methylphosphonic acid, N-methylglyphosate and hydroxymethylphosphonic acid did not cause statistically significant changes in caspase-8 activity (Fig. 4). Glyphosate, its metabolites and impurities caused a substantial increase in caspase-9 activity. Changes in the enzyme activity were observed for the highest concentration (5 mM) of glyphosate, its two metabolites: AMPA and methylphosphonic acid and all glyphosate impurities: PMIDA, N-methylglyphosate, hydroxymethylphosphonic acid and bis(phosphonomethyl)amine (Fig. 5).

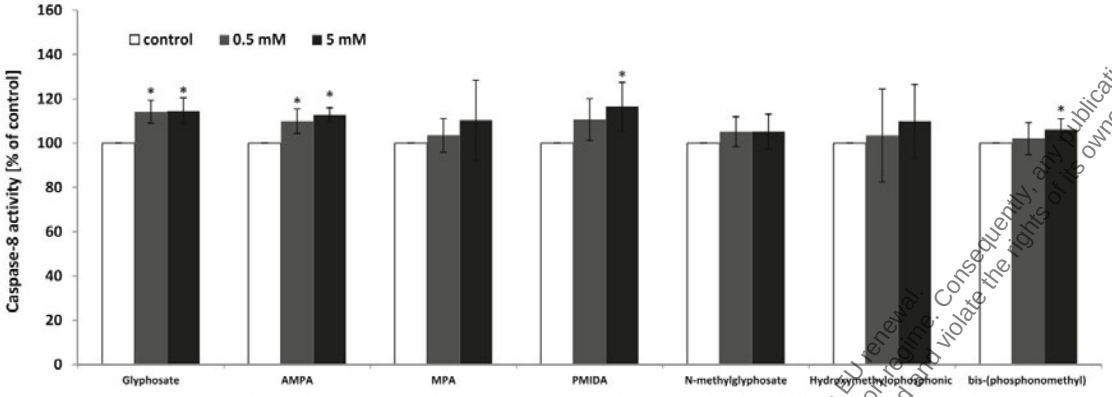

Fig. 4. Changes in caspase-8 activity in PBMCs after 4 h incubation with glyphosate, its metabolites and impurities. (*) Statistically significant changes compared to control ($P < 0.05$).

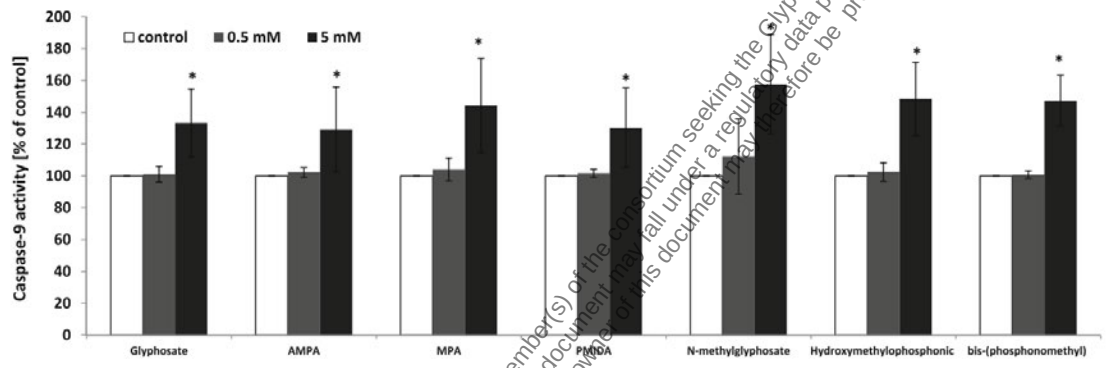

Fig. 5. Changes in caspase-9 activity in PBMCs after 4 h incubation with glyphosate, its metabolites and impurities. (*) Statistically significant changes compared to control ($P < 0.05$).

Caspase-3 activity; An increase in caspase-3 activity was noted in PBMCs treated with 0.25 mM of glyphosate and PMIDA and with 0.5 mM of AMPA, hydroxymethylphosphonic acid and bis-(phosphonomethyl)amine. Other compounds tested: N-methylglyphosate and methylphosphonic acid only at the highest concentration of 5 mM caused an increase in caspase-3 activity (Fig. 6).

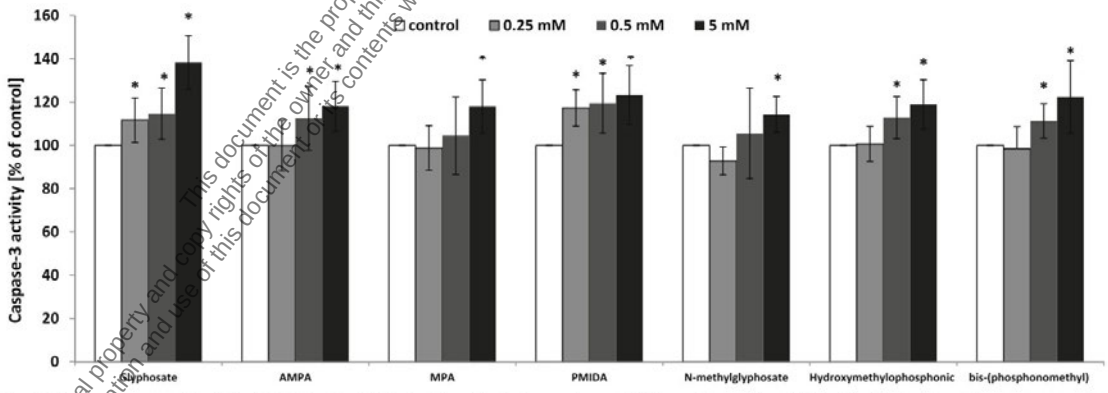

Fig. 6. Changes in caspase-3 activity in PBMCs after 4 h incubation with glyphosate, its metabolites and impurities. (*) Statistically significant changes compared to control ($P < 0.05$).

ROS level; It was observed that glyphosate, its metabolites and impurities induced a statistically significant increase in H2DCFDA oxidation in PBMCs. Changes in ROS level were observed after 4 h of exposure of PBMCs to 0.25 mM of glyphosate, methylphosphonic acid, PMIDA, N-methylglyphosate and hydroxymethylphosphonic acid. Other compounds studied like AMPA and bis-(phosphonomethyl)amine from the concentration of 0.5 mM caused an increase in the H2DCFDA oxidation (Fig. 7).

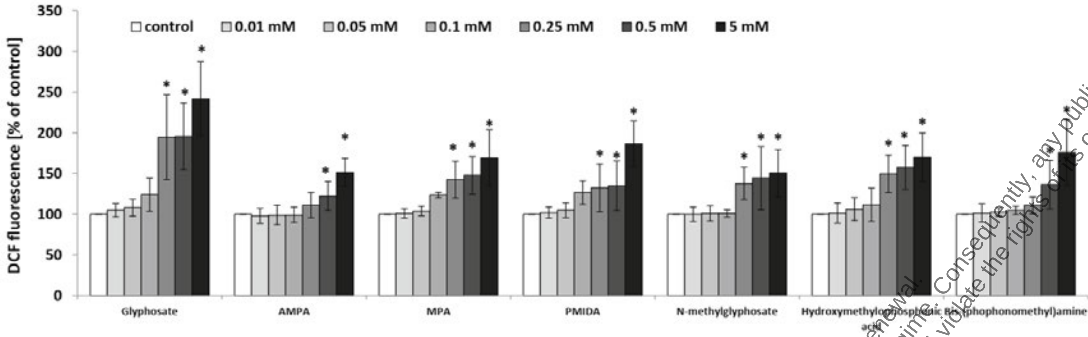

Fig. 7. Changes in total ROS level in PMBCs incubated with glyphosate, its metabolites and impurities for 4 h (*) Statistically significant changes compared to the control (P < 0.05).

Hydroxyl radical level; Glyphosate, its metabolites and impurities increased highly reactive oxygen species level, including hydroxyl radicals in PMBCs. Statistically significant changes were observed for most of the compounds studied from the concentration of 5 mM. An increase in HPF fluorescence was noted in cells treated for 4 h with the highest concentration (5 mM) of glyphosate, its impurities: N-methylglyphosate, hydroxymethylphosphonic acid and bis-(phosphonomethyl)amine and metabolites: AMPA and methylphosphonic acid. The strongest changes in HPF oxidation were caused by PMIDA, which changed this parameter from the concentration of 0.5 mM (Fig. 8).

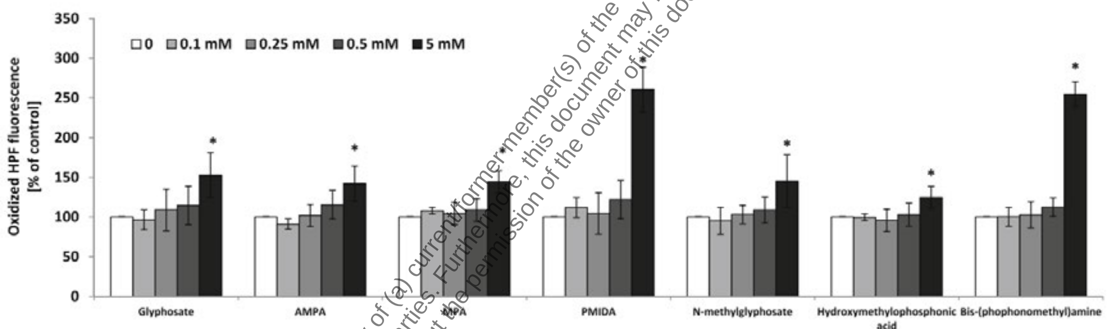

Fig. 8. The level of highly reactive oxygen species (mainly hydroxyl radical) in human PMBCs incubated with glyphosate, its metabolites and impurities for 4 h (*) Statistically significant changes compared to the control (P < 0.05).

Discussion

Apoptotic potential of glyphosate has been evaluated in various cell types; however, the effect of glyphosate, its metabolites (including AMPA and methylphosphonic acid) and its impurities on apoptotic changes in human leucocytes has not been assessed. This study has described apoptotic potential of glyphosate, its metabolites and impurities in human PBMCs. Besides a quantitative determination of apoptotic cells (staining with YO-PRO-1/PI fluorescent probes) the analysis concerned evaluation of the mechanism of action of these substances by measurement of a variety of parameters involved in the programmed cell death. The activities of caspases, of both initiator caspase-8 and -9, as well as executor caspase-3 were determined. Alterations in cytosolic calcium ion and ROS levels were also analysed. Moreover, changes in transmembrane mitochondrial potential and chromatin condensation were assessed. PBMCs were exposed to tested compounds for 4 h, the time necessary to observe apoptotic changes. Flow cytometry analysis has demonstrated a statistically significant increase in the number of apoptotic cells exposed to all compounds studied. Apoptotic changes induced by glyphosate, PMIDA and hydroxymethylphosphonic acid were observed from the concentration of 0.5 mM, while those induced by AMPA, methylphosphonic acid, N-methylglyphosate and bis-(phosphonomethyl)amine from the concentration of 5 mM. A slight increase in the number of apoptotic cells (5.76 %) treated with glyphosate was observed, compared to the control (1.22 %).

It was observed that methylphosphonic acid at lower concentration (0.25 mM) (in comparison to other analysed compounds) caused a statistically significant increase of cytosolic calcium ion level in PBMCs. Other compounds such as methylphosphonic acid and bis(phosphonomethyl)amine induced apoptosis from the concentration of 0.5 mM, while glyphosate, AMPA and N-methylglyphosate from 5 mM. It was also observed that aminomethylphosphonic acid did not cause any statistically significant increase in this parameter.

Our study demonstrated that all compounds analysed caused reduction of transmembrane mitochondrial potential. Glyphosate and its impurity - bis(phosphonomethyl)amine, from the concentration of 0.05 mM, caused reduction of ΔΨm, while other compounds analysed induced the same changes from the concentration of 0.1 mM (except for hydroxymethylphosphonic acid, that caused reduction of the discussed parameter at the concentration of 0.25 mM). An increased ROS production was observed in PBMCs exposed with all analysed compounds. The obtained results are consistent with data published, which observed ROS formation in human PBMCs treated with glyphosate, AMPA and particularly glyphosate preparation - Roundup 360 PLUS. It has been shown that the increase in ROS level, and hydroxyl radical in particular may contribute to DNA damage, and thus apoptotic cell death. For that reason, the formation of highly reactive oxygen species (including hydroxyl radical) was assessed in PBMCs treated with glyphosate, its metabolites and impurities. It has been noted that glyphosate, its impurities: N-methylglyphosate, hydroxymethylphosphonic acid and bis(phosphonomethyl)amine as well as its metabolites: AMPA and methylphosphonic acid at the concentration of 5 mM caused an increase in hydroxyl radical level. The highest increase in this parameter was noted in PBMCs exposed to PMIDA (from 0.5 mM Similarly, our study showed that AMPA at lower concentration did not induce hydroxyl radical formation, and the increase in discussing parameter was noted only at its highest level of 5 mM. The proteolytic activity of caspases involves cleavage of their substrates at aspartate residues. In this study we have observed that glyphosate, its metabolites and impurities caused chromatin condensation in human PBMCs. Based on our own research, and also on studies of other authors it may be suggested that glyphosate, its metabolites and impurities induce apoptosis both via the intrinsic pathway (evidenced by the observed increase in total ROS and hydroxyl radical levels, a decrease in transmembrane mitochondrial potential and an increase in caspase-9 activity), and - to a lesser extent via the extrinsic pathway (evidenced by changes in caspase-8 activity) (except for methylphosphonic acid, Nmethylglyphosate and hydroxymethylphosphonic acid).

III. CONCLUSION

Toxicity of pure glyphosate versus its metabolites and impurities: The results obtained in this study do not indicate an essential role of metabolites and production impurities of glyphosate in toxic (proapoptotic) action of glyphosate and possibly glyphosate-based preparations. Research presented in this paper indicated that both AMPA and MPA exerted a smaller effect on ROS and hydroxyl radical formation than glyphosate. For other analysed parameters, no significant differences have been demonstrated between glyphosate and its metabolites activities. Studies on toxicity of glyphosate metabolite - MPA - are even more limited, while our results clearly demonstrated a relatively low toxicity of this compound. The study also revealed that some of glyphosate impurities were characterized by a slightly stronger proapoptotic potential than the parent compound. They constitute, however, a minor impurities of glyphosate and should not significantly increase toxicity of N-(phosphonomethyl)glycine-based products (contrary to surfactants).
Obtained results clearly indicate low proapoptotic properties of all analysed compounds. Initial clear apoptotic effects are associated with their highest analysed concentrations, which correspond to the concentrations to which a human organism could be exposed only as a result of acute or subacute poisoning with glyphosate.

1. Assessment and conclusion

Assessment and conclusion by applicant:

The study describes in-vitro investigations of glyphosate, its metabolites (AMPA and

methylphosphonic acid) and impurities (PMIDA, N-methylglyphosate, hydroxymethylphosphonic acid, and bis-(phosphonomethyl)amine) on six intermediate endpoints of apoptosis (membrane permeability, cytosolic calcium concentration, mitochondrial transmembrane potential, caspase activity, chromatin condensation, and ROS quantitation by two methods) in human peripheral blood mononuclear cells. The reason for selection of this model is not stated but is possibly as potential target tissue for Non-Hodgkins Lymphoma. The methodologies used are frequently reported in literature but are not a standardized or validated method by GLP standards; there is no OECD guideline. Positive control results are not presented and it is unclear if positive controls were used for all assays; wording is sufficiently poor that it may be inferred that some positive controls were used, e.g. nigericin and valinomycin in the studies of mitochondrial transmembrane potential, campothecin in the caspase assays, although these may alternatively be reagents for the assay. It is unclear if assays were conducted in duplicate or triplicate (the stated term was "trice" which may be either twice or thrice), which may then also influence statistical evaluation. However, the methodology appears basically sound.

Apoptotic or pre-apoptotic activity was seen generally consistently across the assays. While glyphosate, its metabolites, and impurities were seen to increase apoptotic endpoints in these assays (0.5 mM and higher), clear effects occurred only at high concentrations.

This publication is considered relevant for the risk assessment of glyphosate but reliable with restrictions because no proper cytotoxicity tests were performed, no positive controls were used and the concentration range at which most of the effects were observed is beyond the acceptable physiological range (> 1 mM). The concentration range at which the glyphosate impurities were tested is the same as that for glyphosate which is not a realistic approach for risk assessment of impurities.

Studies with N-acetyl AMPA

The metabolite N-acetyl AMPA was investigated for acute oral toxicity, subchronic toxicity and mutagenicity. All studies presented are submitted on EU level for the first time.

The oral LD_{50} for N-acetyl AMPA was determined to be > 5000 mg/kg bw (limit test), based on the results of an acute oral toxicity study in female rats. No death occurred, but diarrhoea and general clinical signs of toxicity were observed in all animals ([redacted], 2007, CA 5.8.1/032).

In a 90-day feeding study in rats, no adverse effects were noted on in-life parameters, neurobehavioral evaluation and clinical and anatomic pathology at any dose tested. Therefore, a NOAEL of 1163 and 1400 mg/kg bw/day was derived for males and females, respectively ([redacted], 2008, CA 5.8.1/033).

N-acetyl AMPA was tested negative for mutagenicity in bacteria (Ames test) and mammalian cells (HPRT test) ([redacted], 2007, CA 5.8.1/034; [redacted] 2007, CA 5.8.1/036). Furthermore, no clastogenic/aneugenic activity was observed in an *in vitro* chromosomal aberration test in human lymphocytes and in an *in vivo* micronucleus test in mice ([redacted], 2007, CA 5.8.1/035; [redacted], 2007, CA 5.8.1/037).

2. Full summary

Executive summary

A single dose of IN-EY252 was administered by oral gavage to 3 fasted female rats at a dose of 5000 mg/kg bw. The rats were dosed one at a time at a minimum of 48-hour intervals. The rats were observed for mortality, body weight effects and clinical signs for 14 days after dosing. All rats were necropsied to detect grossly observable evidence of organ or tissue damage.
No deaths occurred. Clinical signs of toxicity were observed in all rats up to 2 days after dosing and included diarrhoea, dark eyes, lethargy, high posture, stained fur/skin, wet fur, ataxia and/or hyper-reactivity. No body weight losses occurred after dosing. No test substance-related gross lesions were found in the study.
Under the conditions of this study, the oral LD_{50} for IN-EY252 was greater than 5000 mg/kg bw for female rats.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	N-Acetyl AMPA (IN-EY252)
Identification:	[(Acetylamino)methyl]phosphonic acid
Description:	White solid
Lot/Batch #:	(IN-EY252-) 003
Purity:	79 %
Stability of test compound:	The test substance appeared to be stable under the conditions of the study. No evidence of instability, such as a change in colour or physical state was observed. Expiry date: 2010-05-16.
2. Vehicle and/ or positive control:	Deionised water / none
3. Test animals:	
Species:	Rat
Strain:	Crl:CD(SD)
Source:	[redacted]

Age:	10 – 11 weeks
Sex:	Female
Weight at dosing:	207.9 – 216.2 g
Acclimation period:	6 days
Diet/Food:	PMI® Nutrition International, LLC Certified Rodent LabDiet® 5002, *ad libitum*
Water:	Water, *ad libitum*
Housing:	Individually in stainless steel, wire-mesh cages suspended above cage boards
Environmental conditions:	Temperature: 18 – 26 °C Humidity: 30 – 70 % Air changes: Not reported 12 hours light / dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 2007-08-28 to 2007-09-12

Animal assignment and treatment:
A single oral dose of IN-EY252, suspended in deionised water, was administered by oral gavage to 3 fasted female rats at a dose of 5000 mg/kg bw. The rats were dosed one at a time at a minimum of 48-hour intervals. The rats were fasted approximately 16 – 18 hours prior to dosing, with food being returned to the rats approximately 3 – 4 hours after dosing. Individual dose volumes were calculated using the fasted body weights obtained prior to dosing. The rats were dosed at a volume of 20 mL per kg of body weight. The dosing suspensions were stirred throughout the dosing procedure.

Clinical observations
Observations for signs of illness, injury or abnormal behaviour were made daily.
The rats were observed for clinical signs at the beginning of fasting, just before dosing (test day 0), once during the first 30 minutes after dosing and 2 more times on the day of dosing and once each day thereafter for the 14 day observation period.

Body weight
The rats were weighed on test days –1, 0, 7 and 14.

Sacrifice and pathology
On test day 14, the rats were anesthetised by carbon dioxide, euthanised by exsanguination and necropsied to detect grossly observable evidence of organ or tissue damage.

II. RESULTS AND DISCUSSION

A. MORTALITY

There were no animals found dead or killed *in extremis* in any group during the treatment period.

B. CLINICAL OBSERVATIONS

Clinical signs of toxicity were observed in all rats up to 2 days after dosing and included diarrhoea, dark eyes, lethargy, high posture, stained fur/skin (abdomen, yellow; inguen, yellow or brown; perineum, yellow or brown), wet fur (perineum), ataxia and/or hyper-reactivity.

C. BODY WEIGHT

No body weight losses occurred after dosing.

D. NECROPSY

Gross pathology

No test substance-related gross lesions were found in the study. The only gross lesion observed, uterus dilatation in rat 3308, was non-specific and not indicative of target organ toxicity.

III. CONCLUSIONS

Under the conditions of this study, the oral LD_{50} for IN-EY252 was greater than 5000 mg/kg bw for female rats.

3. Assessment and conclusion

Assessment and conclusion by applicant:

This study is considered to be valid as it was conducted under GLP and no deviations from the recent guideline could be identified.

Under the conditions of this study, the oral LD_{50} for IN-EY252 was greater than 5000 mg/kg bw for female rats.

Assessment and conclusion by RMS:

Short-term toxicity

CA 5.8.1/033

1. Information on the study

Data point	CA 5.8.1
Report author	[redacted]
Report year	2008
Report title	IN-EY252: Subchronic Toxicity 90-Day Feeding Study in Rats
Report No	[redacted]-23316
Document No	n.a.
Guidelines followed in study	OPPTS 870.3100 (1998); OECD Guideline 408 (1998)
Deviations from current test guideline (OECD 408, 2018)	Clinical chemistry was performed without determining LDL, HDL, T3, T4 and TSH; organ weights were determined without prostate (+seminal vesicles and coagulating glands), thyroid and pituitary gland; histopathology was performed without coagulating glands, gall bladder and male mammary glands.
Previous evaluation	No, not previously submitted
GLP/Officially recognised	Yes

testing facilities	
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

In a 90-day feeding study, IN-EY252 technical was administered to male and female Crl:CD(SD) rats (10 rats/sex/concentration) at concentrations of 0, 900, 6000, and 18000 ppm (equivalent to 0, 55, 374 and 1163 mg/kg bw/day for males and 0, 68, 455 and 1400 mg/kg bw/day for females). Parameters evaluated included body weight, body weight gain, food consumption, food efficiency, clinical signs, abbreviated functional observational battery (FOB), haematology, clinical chemistry, urinalysis, ophthalmology, organ weights and gross and microscopic pathology.

No adverse effects were noted in any of the parameters examined. Test substance-related clinical signs, soft faeces, and dried and/or wet brown material around the anogenital area were observed in 18000 ppm group males and females. Final body weights (test day 91) and overall body weight gains (test day 0 – 91) in males and females were 7.6 % and 5.0 % and 11.5 % and 9.3 %, respectively, lower (statistically non-significant) than controls in the 18000 ppm group. These changes were considered test substance related, but not adverse.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	N-Acetyl AMPA (IN-EY252)
Identification:	[(Acetylamino)methyl]phosphonic acid
Description:	Solid
Lot/Batch #:	(IN-EY252-) 003
Purity:	79 %
Stability of test compound:	The test substance appeared to be stable under the conditions of the study. No evidence of instability, such as a change in colour or physical state was observed. Expiry date: 2010-05-16.
2. Vehicle and/ or positive control:	Diet / none
3. Test animals:	
Species:	Rat
Strain:	Crl:CD(SD)
Source:	[redacted]
Age:	Approximately 8 weeks
Sex:	Male and female
Weight at dosing:	♂ 237 – 333 g; ♀ 164 – 212 g
Acclimation period:	20 days
Diet/Food:	PMI® Nutrition International, LLC Certified Rodent LabDiet® 5002, *ad libitum*
Water:	Reverse osmosis-treated (on-site) drinking water, *ad libitum*

Housing:	Individually in stainless steel, wire-mesh cages suspended above cage boards	
Environmental conditions:	Temperature:	22 ± 3 °C (21.8 – 22.1 °C)
	Humidity:	50 ± 20 % (36.7 – 62.4 %)
	Air changes:	10 air changes / hour
	12 hours light / dark cycle	

B. STUDY DESIGN AND METHODS

In life dates: 2007-08-20 to 2007-11-19/20

Animal assignment and treatment:
The test substance, IN-EY252, was administered on a continuous basis in the basal diet for 90 or 91 days to 3 groups (Groups 2 – 4) of Crl:CD(SD) rats. Dose levels were 900, 6000 and 18000 ppm. A concurrent control group (Group 1) received the basal diet on a comparable regimen. Each group consisted of 10 animals per sex.

Table 5.8.1-76: IN-EY252: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2008): Study design

Test group	Dietary concentration [ppm]	Mean daily intake mg/kg bw/day	Number of animals	
			Males	Females
Control	0	♂: 0; ♀: 0	10	10
Low	900	♂: 55; ♀: 68	10	10
Intermediate	6000	♂: 374; ♀: 455	10	10
High	18000	♂: 1163; ♀: 1400	10	10

Analysis of the test substance
Prior to the initiation of dose administration, quadruplicate samples (approximately 25 g each) for homogeneity determination were collected from the top, middle and bottom strata of the 900, 6000 and 18000 ppm test diet preparations. In addition, quadruplicate samples (approximately 25 g each) for stability determinations were collected from the middle strata of these same test diet preparations at dietary levels of 900 and 18000 ppm and stored at room temperature or refrigerated for 7 or 15 days. Quadruplicate samples (approximately 25 g each) for concentration analyses were collected from the middle stratum of each test diet preparation, including the diet preparation administered to the control group, prepared on study week 0, study week 6 and study week 12. Two samples from each set of 4 samples collected were shipped frozen to the Sponsor, DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, Delaware, for analysis. The remaining samples from each sample set were kept frozen at [redacted], and were retained as back-up samples. In addition, a 100 g sample of the basal diet was shipped to the sponsor with each shipment of test diet samples. The basal diet was used by the sponsor to prepare matrix-matched analytical chemistry standards for the homogeneity, stability and confirmation of concentration analyses.

Mortality
All animals were observed twice daily, once in the morning and once in the afternoon, for mortality and moribundity.

Clinical observations
Clinical examinations were performed once daily for all animals. The daily observations were performed at approximately the same time each day and were omitted on days of detailed physical examinations. All significant findings were recorded. Detailed physical examinations were conducted on all animals weekly, beginning 1 week prior to test substance administration and prior to the scheduled necropsy. A separate computer protocol was used to record any observations noted outside of the above-specified intervals.

Body weight
Individual body weights were recorded at least weekly, beginning 3 weeks prior to test substance administration (study week -3). Mean body weights and mean body weight changes were calculated for the corresponding intervals. Final body weights were recorded on the day prior to (un-fasted) and on the day of (fasted) the scheduled necropsy.

Food consumption and test substance intake
Individual food consumption was recorded weekly, beginning 3 weeks prior to test substance administration (study week -3 to -2). Food intake was calculated as g/animal/day for the corresponding body weight intervals. Food efficiency (body weight gained as a percentage of food consumed) was also calculated and reported for these intervals.
The mean amounts of test substance consumed (mg/kg bw/day) by each sex of each dietary group was calculated from the mean food consumed (g/kg of bw/day) and the appropriate target concentration of test substance in the food (mg/kg of diet).

Abbreviated Functional Observational Battery (FOB)
Abbreviated functional observational battery (FOB) assessments were recorded for all animals prior to the initiation of dose administration and during study week 12. Testing was performed by the same trained technicians, whenever possible, without knowledge of the animals' group assignments. The FOB was performed in a sound-attenuated room equipped with a white-noise generator set to operate at 70 ± 10 dB, to minimise environmental variations in the test conditions. The FOB used at [redacted] is based on previously developed protocols ([redacted], 1991; [redacted], 1968; [redacted], 1982; [redacted]., 1988; [redacted], 1989; [redacted], 1989). All animals were observed for the following parameters as described below:

1. Home Cage Observations: Feces consistency
2. Sensory Observations: Approach response, startle response, pupil response, touch response and tail pinch response
3. Neuromuscular Observations: Grip strength - hind and forelimb

Locomotor activity
Locomotor activity was assessed for all animals prior to the initiation of dose administration and during study week 12. Locomotor activity, recorded after the completion of the abbreviated FOB, was measured automatically using the SDI Photobeam Activity System (San Diego Instruments, Inc., San Diego, California). This personal computer-controlled system utilised a series of infrared photobeams surrounding a clear plastic, rectangular cage to quantify the motor activity of each animal. Four-sided black plastic enclosures were used to surround the clear plastic boxes and decrease the potential for distraction from extraneous environmental stimuli or activity by technicians or adjacent animals. The black enclosures rested on top of the photobeam frame and did not interfere with the path of the beams. The locomotor activity assessment was performed in a sound-attenuated room equipped with a white-noise generator set to operate at 70 ± 10 dB, to minimise environmental variations in the test conditions. The testing of treatment groups was conducted according to replicate sequence. Each animal was tested separately. Data were collected in 5-minute epochs and the test session duration was 60 minutes. These data were compiled as four 15-minute sub-sessions for tabulation.
Data for ambulatory and total motor activity were tabulated. Total motor activity was defined as a combination of fine motor skills (i.e., grooming, interruption of 1 photobeam) and ambulatory motor activity (interruption of 2 or more consecutive photobeams).

Ophthalmoscopic examination
Ocular examinations were conducted on all animals prior to the initiation of dose administration (study week -3) and near the end of the treatment period (study week 12). All ocular examinations were conducted using an indirect ophthalmoscope and slit lamp biomicroscope preceded by pupillary dilation with tropicamide ophthalmic solution, USP, 0.5 %.

Haematology, clinical chemistry and urinalysis

Blood and urine samples for clinical pathology evaluations (haematology, coagulation, serum chemistry and urinalysis) were collected from all surviving animals at the scheduled necropsy (study week 13). In addition, blood samples for clinical pathology evaluations (haematology, coagulation and serum chemistry) were collected and analysed from the Group 3 male euthanised *in extremis* (prior to euthanisation). The animals (excluding the animal euthanised *in extremis*) were fasted overnight prior to blood collection while in metabolism cages for urine collection. Blood was collected for haematology and serum chemistry evaluation via the retro-orbital sinus of animals anesthetised by inhalation of isoflurane. Blood samples for analysis of coagulation parameters were collected at the time of euthanasia via the *vena cava* of animals' euthanised by inhalation of carbon dioxide. Blood was collected into tubes containing EDTA (haematology), sodium citrate (clotting determinations) or no anticoagulant (serum chemistry).

The following haematological parameters were evaluated: Blood smears, total leukocyte count, erythrocyte count, haemoglobin, haematocrit, mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC), platelet count, prothrombin time, activated partial thromboplastin time (APTT), reticulocyte count (percent/absolute) and differential leukocyte count (percent and absolute: Neutrophil, lymphocyte, monocyte, eosinophil, basophil and large unstained cells).

The following clinical chemistry parameters were evaluated: Albumin, total protein, globulin, albumin/globulin ratio (A/G Ratio), total bilirubin (Total Bili), urea nitrogen, creatinine, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, gamma glutamyl-transferase, glucose, total cholesterol, calcium, chloride, phosphorus, potassium, sodium, sorbitol dehydrogenase and triglycerides.

The following urinalysis parameter were evaluated: Specific gravity, pH, urobilinogen, total volume, colour, clarity, protein, glucose, ketones, bilirubin, occult blood, leukocytes, nitrites, microscopy of sediment and osmolality.

Sacrifice and pathology

Gross pathology

A complete necropsy was conducted on all animals. Animals were euthanised by carbon dioxide anaesthesia and exsanguinated. The necropsies included, but were not limited to, examination of the external surface, all orifices, and the cranial, thoracic, abdominal and pelvic cavities, including viscera.

Organ weights

The following organs were weighed from all animals at the scheduled necropsy: Adrenals, brain, epididymides, heart, kidneys, liver, ovaries with oviducts, spleen, testes, thymus and uterus. Paired organs were weighed together. Organ / body weight and organ / brain weight ratios were calculated.

Histopathology

After fixation, protocol-specified tissues were trimmed according to standard operating procedures and the protocol. Trimmed tissues were processed into paraffin blocks, sectioned at 4 to 8 microns, mounted on glass microscope slides and stained with haematoxylin and eosin. The following organs were examined: Adrenals, aorta, bone with marrow (with femur and sternum), bone marrow smear, brain, cervix, epididymides, exorbital lacrimal glands, eyes with optic nerve, oesophagus, stomach, duodenum, jejunum, ileum, Peyer's Patches, caecum, colon, rectum, heart, kidneys, larynx, liver, lungs, lymph nodes (mandibular and mesenteric), nasal cavity, mammary gland (females only), ovaries (with oviducts), pancreas, peripheral nerve (sciatic), pharynx, pituitary, prostate, salivary glands (mandibular), seminal vesicles, skeletal muscle (rectus femoris), skin, spinal cord (cervical, thoracic, lumbar), spleen, testes, thymus, thyroid/parathyroids, tongue, trachea, urinary bladder, uterus, vagina and all gross lesions and masses.

Statistics

Body weight, food intake parameters, abbreviated FOB, clinical pathology, and organ weight data were subjected to a parametric one-way analysis of variance (ANOVA) to determine intergroup differences. If the ANOVA revealed statistically significant ($p<0.05$) intergroup variance, Dunnett's test was used. Functional observational battery parameters that yielded scalar or descriptive data were analysed using

Fisher's Exact Test. Non-parametric statistical analysis was conducted for gamma glutamyl transferase.

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSIS

Homogeneity and stability were verified prior to study start and concentration verification was done 3 times during the study (start, middle and end). The test substance was at target concentrations (95.6 – 109.4 % nominal), homogeneous (94.2 – 102.2 % nominal) throughout the feed, and was stable (88.3 – 111.1 %) for up to 15 days at room temperature. Based on this information, it can be concluded that the animals received the targeted dietary concentrations of test substance during the study.

B. MORTALITY

One 6000 ppm group male was euthanised *in extremis* on study day 36, which was associated with nasal cavity fractures and was unrelated to test substance administration. Clinical observations noted in this male included dermal atonia, gasping, upper and lower incisors malaligned/broken, red material around the left and right eyes, soft faeces, decreased defecation, smaller than normal faeces, dried yellow material around the urogenital area and dried brown material around the anogenital area.
Additionally one control group male was found dead on study day 71. The cause of death was undetermined, as there were no significant or remarkable clinical findings for this animal throughout the study or at the unscheduled necropsy.

None of the deaths was related to treatment.

C. CLINICAL OBSERVATIONS

Clinical findings were primarily limited to the 18000 ppm group males and females and included occurrences of soft faeces and dried and/or wet brown material around the anogenital area. These clinical findings were considered to be test substance-related, but non-adverse. Other clinical signs were common findings for laboratory rats of this age and strain.

D. BODY WEIGHT

There were no adverse effects on body weights or body weight gains. Final body weights (test day 91) were 7.6 % and 5 % lower than controls in the 18000 ppm males and females, respectively. Overall (test day 0 – 91) body weight gains were 11.5 % and 9.3 % lower than controls in the 18000 ppm males and females, respectively (or there were no test substance-related effects on body weights or body weight gains). These changes were not statistically significant and not adverse. No changes were observed in lower groups.

Table 5.8.1-77: IN-EY252: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2008): Body weight, body weight gain, food consumption and food efficiency

	Dose group [ppm]							
	Males				Females			
	0	900	6000	18000	0	900	6000	18000
Final body weight [g], (% control)	593	↓561 (95 %)	↓563 (95 %)	↓548 (92 %)	305	↓312 (98 %)	↓302 (99 %)	↓290 (95 %)
Body weight gain [g], (% control)	304	↓277 (91 %)	↓282 (93 %)	↓269 (88 %)	118	↑123 (104 %)	↓115 (97 %)	↓107 (91 %)
Food consumption [g], (% control)	29	↓27 (93 %)	↓28 (97 %)	↓28 (97 %)	20	20 (100 %)	20 (100 %)	20 (100 %)
Food efficiency [g bw gain/g FC], (% control)	11	11 (100 %)	↓7 (64 %)	↓10 (91 %)	6	↑7 (117 %)	6 (100 %)	6 (100 %)

E. FOOD COMSUMPTION; FOOD EFFICIENCY AND DAILY INTAKE

There were no test substance-related effects on food consumption and food efficiency. The mean daily intakes for male rats were 0, 55, 374 and 1163 mg/kg bw/day. The mean daily intakes for female rats were 0, 68, 455 and 1400 mg/kg bw/day.

F. OPHTHALMOLOGICAL EXAMINATIONS

There were no test substance-related ophthalmoscopically visible changes in the eyes of either male or female rats at any dietary concentration.

G. NEUROBEHAVIORAL EVALUATIONS

There were no definitive test substance-related effects on sensory or neuromuscular parameters at the study week 12 abbreviated FOB evaluations.

Home cage observations

Test substance-related effects on home cage parameters included a statistically significantly greater number of 18000 ppm group males (10/10 animals) and females (7/10 animals) with partially formed pellets (faeces consistency) in comparison to the control group males (0/10 animals) and females (0/10 animals) during the study week 12 evaluation. These home cage observations are consistent with the abnormal excreta observations (soft faeces and dried and/or wet brown material around the anogenital area) noted in the 18000 ppm group animals during the daily clinical examinations and are considered to be non-adverse.

Sensory Observations

There were no test substance-related effects on sensory parameters when the test substance-treated males and females were compared to the control group at the study week 12 abbreviated FOB evaluations.

Neuromuscular Observations

There were no test substance-related effects on neuromuscular parameters when the test substance-treated males and females were compared to the control group at the study week 12 abbreviated FOB evaluations. Males in the 18000 ppm group had slightly lower forelimb and hind limb grip strength compared to the control group during the study week 12 evaluation. Since the difference was also present at the pre-test evaluation, the slightly lower grip strength during the study week 12 evaluation in the 18000 ppm group males was not considered to be test substance-related. Females in the 18000 ppm group also had slightly lower grip strength compared to the control group during the study week 12 evaluation. Since cumulative body weight gain for the 18000 ppm group males and females was slightly lower compared to the respective control group, the slightly lower grip strength in the 18000 ppm group males and females may also be secondary to the lower cumulative body weight gain in this group

Locomotor Activity

Within-session repeated measures analyses of variance were conducted across the subintervals of each test session for total and ambulatory counts and for overall interval means (representing the entire 60-minute session activity) during each test session. Locomotor activity patterns (mean ambulatory and total motor activity counts) were unaffected by test substance administration. There were no statistically significant differences for the test substance-treated males and females when compared to the control group during study week 12. Values obtained from the four epochs (0 – 15 minutes, 16 – 30 minutes, 31 – 45 minutes and 46 – 60 minutes) evaluated and the overall 60-minute test session values were comparable to the concurrent control values. No remarkable shifts in the pattern of habituation occurred in any of the test substance-treated groups when the animals were evaluated during study week 12.

H. HAEMATOLOGY, CLINICAL CHEMISTRY AND URINALIYIS

There were no test substance-related alterations in haematology, serum chemistry and urinalysis parameters.

Haematology

A statistically significant higher prothrombin time in the 18000 ppm group males was noted at study week

13 but was not toxicologically significant because the increase was very small and well within the [redacted] Historical Control Range Version 2.5 (reference range of 13.0 – 19.6 seconds from 15 studies).

Table 5.8.1-78: IN-EY252: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2008): Selected haematological parameters

Parameter	Dose group [ppm]							
	Males				Females			
	0	900	6000	18000	0	900	6000	18000
Prothrombin time [s]	13.1 ± 0.56	↑13.4 ± 0.43	↑13.5 ± 0.81	**↑14.3* ± 1.26**	12.6 ± 0.36	↓12.3 ± 0.58	↓12.3 ± 0.60	↓12.4 ± 0.53

*: Statistically significant from control ($p<0.05$)

Clinical Chemistry
There were no test substance-related alterations in serum chemistry parameters.

Urinalysis
Urine pH was 9 % lower in the 18000 ppm group males at study week 13. Eighty percent of the 18000 ppm group males had a urine pH of 6.0, compared with 0 %, 10 % and 20 % of 0, 900 and 6000 ppm group males at study week 13. Urine volume was 51 % lower and osmolality was 41 % higher in the 18000 ppm group males at study week 13 and the small change in urine pH may have been related to concentrated urine and was not adverse.

Table 5.8.1-79: IN-EY252: Subchronic Toxicity 90-Day Feeding Study in Rats [redacted], 2008): Selected urinalysis parameters

Parameter	Dose group [ppm]							
	Males				Females			
	0	900	6000	18000	0	900	6000	18000
pH value	6.7 ± 0.26	↓6.5 ± 0.44	↓6.6 ± 0.39	**↓6.1** ± 0.21**	6.3 ± 0.35	↑6.5 ± 0.41	↓6.1 ± 0.46	↓6.2 ± 0.35
Urine volume [mL]	8.9 ± 4.51	↓6.7 ± 3.92	↓8.7 ± 5.24	↓4.4 ± 1.96	8.7 ± 10.52	↓5.5 ± 4.3	↓4.1 ± 1.73	↓5.6 ± 2.95
Osmolality [mOsm/kg]	1378 ± 418.6	↑1388 ± 521.4	↓1275 ± 531.3	↑1944 ± 618.1	1089 ± 484.7	↑1215 ± 568.9	↑1433 ± 615.4	↓1012 ± 453.3

**: Statistically significant from control ($p<0.01$)

I. NECROPSY

No test substance-related changes in mean organ weights (absolute or relative) and gross lesions were observed at any dietary concentration. There were no test substance-related microscopic findings in the male or female 18000 ppm groups.

Histopathology
Inflammation was multifocally present within the lungs of individuals throughout the control and 18000 ppm groups (6/10 and 8/10 males and 5/10 and 8/10 females in the control and 18000 ppm groups, respectively). A mixed population of inflammatory cells consisting primarily of mononuclear cells (macrophages and lymphocytes) occasionally admixed with low numbers of neutrophils was typically noted in perivascular areas. Occasionally, inflammatory infiltrate extended into adjacent parenchyma and was associated with septal thickening and alveolar infiltration. This idiopathic pulmonary lesion has been described in multiple rat strains, and the most severe lesions occur in 10 – 12 week old animals. Lesions appear to be transient, with apparent resolution in older rats, and etiology remains undetermined although a viral agent is suspected ([redacted] 1997; [redacted]., 1997; [redacted]., 1998). The inflammatory lesion observed in this study is consistent with those reported and the presence of this lesion did not hinder histopathological evaluation of potential test substance-related effects. There were no test substance-related

alterations in the lungs.
Remaining histologic changes were considered to be incidental findings or related to some aspect of experimental manipulation other than administration of the test substance. There was no test substance-related alteration in the prevalence, severity or histologic character of those incidental tissue alterations.

III. CONCLUSIONS

There were no indications of systemic toxicity when IN-EY252 was administered on a continuous basis in the basal diet for 90 or 91 days to 3 groups (Groups 2 – 4) of Crl:CD(SD) rats at dose levels of 900, 6000 and 18000 ppm. IN-EY252 was well tolerated with no adverse effects on clinical observations, body weights, food consumption, FOB parameters and clinical pathology parameters. In addition, there were no ophthalmic, histologic or gross alterations related to test substance administration. Therefore, the no-observed-adverse-effect level (NOAEL) in this study for administration of IN-EY252 on a continuous basis in the basal diet for 90 or 91 days to Crl:CD(SD) rats was 18000 ppm (equivalent to 1163 and 1400 mg/kg bw/day for males and females, respectively).

3. Assessment and conclusion

Assessment and conclusion by applicant:
Despite the deviations in clinical chemistry (LDL, HDL, T3, T4 and TSH not determined), organ weights (prostate + seminal vesicles and coagulating glands), thyroid and pituitary gland not determined) and histopathology (coagulating glands, gall bladder and male mammary glands not examined) this study was conducted under GLP and was considered to be valid.
Based on a lack of adverse effects on in-life parameters, neurobehavioral evaluation and clinical and anatomic pathology in males and females at any dose level, the NOAEL for males and females was 18000 ppm (equivalent to 1163 and 1400 mg/kg bw/day, respectively).

Assessment and conclusion by RMS:

Genotoxicity

2. Full summary

Executive summary

[(Acetylamino)methyl]phosphonic acid (IN-EY252, batch: IN-EY252-001, purity: 76 %), metabolite of glyphosate was investigated for its potential to cause gene mutation in bacteria (Ames test). *S. typhimurium* strains TA 98, TA 100, TA 1535 and TA 1537 and *E. coli* strain WP2 uvrA were exposed to the test item, solvent (water) and appropriate positive controls in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). A preliminary cytotoxicity and mutagenicity experiment was performed to identify cytotoxic concentrations of the test item. In a standard plate test (plate incorporation method), test item concentrations in the range of 1.5 to 5000 µg/plate were applied in the presence and absence of S9 mix. No cytotoxicity was observed in any tester strain up to the highest tested concentration, neither in the presence, nor in the absence of S9 mix.

The preliminary experiment was designated Experiment B1 of the main mutation assay. However, as no bacterial growth was observed on the tester strain plates TA 1535, TA 1537 and WP2 uvrA in the presence and absence of S9 mix, a repeat experiment was conducted with the respective strains (Experiment B2). In addition, a second standard plate test (Experiment B3) was performed using concentrations in the range of 50 – 5000 µg/plate. Both experiments were performed with triplicate plates. After 48 – 72 hours of incubation at 37 ± 2 °C, the bacterial background lawn was examined and the number of revertant colonies were counted for each plate.

Precipitation of the test item in vehicle or cytotoxicity, evident as a reduction in the number of revertant colonies or in the bacterial background lawn were not observed for any strain in any tested concentration, neither with nor without S9 mix.

There was no statistically significant and biologically relevant increase in the number of his^+ or trp^+ revertant colonies observed in any experiment for any strain at any concentration, neither in the presence nor in the absence of metabolic activation. The number of revertant colonies induced by the solvent and the positive controls were within the range of the laboratories historical control data, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

Under the conditions of the test, [(Acetylamino)methyl]phosphonic acid, metabolite of glyphosate, is not mutagenic in the Ames standard plate test with and without metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	[(Acetylamino)methyl]phosphonic acid (metabolite of glyphosate)
Identification:	IN-EY252
Description:	White powder
Lot/Batch number:	IN-EY252-001
Purity:	76 %
Stability of test compound:	The stability of the test item at storage conditions (at room temperature in the dark with desiccant) was guaranteed until the reported expiry date 25 Apr 2009. The stability of the test item in solvent was confirmed by analytical methods.
Solvent (vehicle) used:	Water

2. Control materials:

Negative control:	A negative control was not employed in this study.

Solvent (vehicle) control: Water

Solvent (vehicle)/final concentration: 0.1 mL per plate.

Positive controls: Please refer to table below.

Strain	Metabolic activation	Mutagen	Conc. [µg/plate]
S. typhimurium strains			
TA 100	-S9	Sodium azide	1.0
	+S9	2-Aminoanthracene[#]	1.0
TA 1535	-S9	Sodium azide	1.0
	+S9	2-Aminoanthracene[#]	1.0
TA 98	-S9	2-Nitrofluorene	1.0
	+S9	2-Aminoanthracene[#]	1.0
TA 1537	-S9	9-Aminoacridine	75.0
	+S9	2-Aminoanthracene[#]	1.0
E. coli strains			
WP2 uvrA	-S9	Methyl methanesulfonate	1000.0
	+S9	2-Aminoanthracene[#]	10.0

[#]: The functionality of the S9 mix batch used was additionally checked with 7,12-dimethylbenz(a)anthracene and showed the expected results.

3. Metabolic activation:

S9 mix was purchased from [redacted] and obtained from the livers of male Sprague-Dawley rats. The animals received a single intraperitoneal injection of Aroclor 1254 at a dose of 500 mg/kg bw. The livers were prepared 5 days after treatment. The S9-mix was thawed prior to each experiment and co-factors were immediately added to prepare S9 mix containing the following components:

S9 mix component	Concentration	Unit
Phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	10	% (v/v)

4. Test organisms:

Tester strains				Bacteria batch checked for	
S. typhimurium		***E.coli***			
TA 98	✓	WP2 uvrA	✓	deep rough character (rfa)	✓
TA 100	✓	WP2 uvrA (pKM101)		ampicillin resistance (R factor plasmid)	✓
TA 1535	✓			UV-light sensitivity (absence of uvrB and uvrA genes in *S. typhimurium* and *E. coli* strains, respectively)	✓
TA 1537	✓				
TA 1538				Histidine auxotrophy (automatically via the spontaneous rate)	✓

5. Test concentrations:

(a) Preliminary cytotoxicity and mutagenicity test / Experiments B1 & B2 of the main mutation assay:

Plate incorporation test ± S9 mix:	

Concentrations:	*1.5, 5, 15, 50, 150, 500, 1500 and 5000 µg/plate**	
Tester strains:	TA 98, TA 100, TA 1535, TA 1537 and WP2uvrA	
Replicates:	*Duplicate*	

* *Dosing solutions were adjusted to compensate the purity of the test substance (76 %) by using a correction factor of 1.45.*

(b) Experiment B3 of the main mutation assay:

Plate incorporation test ± S9 mix:	
Concentrations:	*50, 150, 500, 1500 and 5000 µg/plate**
Tester strains:	TA 98, TA 100, TA 1535, TA 1537 and WP2uvrA
Replicates:	*Triplicates*

*: Dosing solutions were adjusted to compensate the purity of the test substance (76 %) by using a correction factor of 1.45.

B: Study design and methods

Dates of experimental work: 01 – 21 Mar 2007
Finalisation date: 23 Jul 2007

1. Standard plate test (plate-incorporation test, SPT):
An aliquot of 0.1 mL test solution, vehicle or positive control, an aliquot of 0.1 mL fresh bacterial culture and 0.5 mL S9 mix (in tests with metabolic activation only) or S9 substitution buffer (in tests without S9 mix) were added to 2 mL of molten selective top agar (supplemented with 0.05 mM L-histidine + 0.05 mM L-biotin or 0.05 mM L-tryptophan). When plating the positive controls, the test item solution was replaced by 50 µL aliquot of the respective positive control. After vortexing, the mixture was overlaid onto the surface of a minimal bottom agar plate. After the overlay had solidified, the plates were inverted and incubated for approx. 48 – 72 hours at 37 ± 2 °C. Following incubation, the bacterial background lawn was examined and the number of his^+ revertant colonies were counted. Plates that were not counted immediately following the incubation period were stored at 2 – 8 °C until evaluation. Each concentration and the controls were tested in triplicates.

2. Cytotoxicity
Toxicity was detected by a

- reduction in the number of spontaneous revertants by > 50 %. The reduction must have been accompanied by an abrupt dose-dependent drop in the revertant count.
- clearing or diminution of the background lawn (= reduced his^- or trp^- background growth)

and recorded for all test groups both with and without S9 mix in all experiments.

3. Statistics
For each replicate plating, the mean and standard deviation of the number of revertants per plate were calculated. No further statistical analysis was performed.

4. Acceptance criteria
The test was considered valid if the following criteria were met:

- All bacterial cultures demonstrated the characteristic mean number of spontaneous revertants in the vehicle controls.
- To ensure that appropriate numbers of bacteria were plated, tester strain cultures must have been greater or equal to 0.3 x 10^9 cells/mL.
- The mean of each positive control exhibited at least a 3.0-fold increase in the number of revertants over the mean value of the respective vehicle control.
- A minimum of 3 non-toxic dose levels were included for the evaluation of data.

5. Evaluation criteria

A test item was considered positive (mutagenic) in the assay if the following criteria were met:

- There was a dose-related increase in the mean number of revertants per plate in at least one tester strain over a minimum of two increasing concentrations of the test substance when compared to the vehicle control.
- The increase in the mean number of revertant colonies per plate were at least 3.0-fold for tester strains TA 1535 and TA 1537 and at least 2.0-fold for tester strains TA 98, TA 100 and WP2uvrA.

An equivocal response was obtained if there was a biologically relevant increase in the number of revertants that partially met the criteria for evaluation as a positive substance. This was for example the case if a dose-responsive increase did not achieve the respective threshold or if a non-dose-responsive increase was equal to or greater than the respective threshold.

A test item was considered negative (non-mutagenic) if it was neither evaluated positive nor equivocal.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

Analytical determinations of test item solutions in vehicle were performed for the concentrations 0.5, 5 and 50 mg/mL. Concentrations were measured by high performance liquid chromatography (HPLC) and UV detection. The actual concentrations were between 106 – 110 % of the target, meeting the acceptance criteria of 85 – 115 % of target. There was no test substance in the 0 mg/mL sample. Stability analysis showed that the test substance in vehicle was stable for approx. 4 hours when stored at room temperature.

B. CYTOTOXICITY

In the preliminary toxicity and mutagenicity test / Experiments B1 and B2 of the main mutation assay there was no cytotoxicity observed up to the highest tested concentration, neither in the presence, nor absence of metabolic activation. Due to the lack of bacterial growth on all assay plates, tester strains TA 1535, TA 1537 and WP2 uvrA in the presence and absence of S9 mix were not evaluated in experiment B1, but were re-tested in an independent experiment (Experiment B2).

In the second experiment of the main mutagenicity assay (Experiment B3) there was no cytotoxicity in any tester strain at any tested concentration, neither in the presence nor absence of S9 mix.

C. SOLUBILITY

Precipitation of the test substance in vehicle was not observed.

D. MUTATION ASSAY

There was no biologically relevant increase in the number of his^+ or trp^+ revertant colonies observed in any experiment for any strain at any concentration, neither in the presence nor in the absence of metabolic activation.

The number of revertant colonies induced by the solvent and the positive controls were within the range of the laboratories historical control data, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

III. CONCLUSIONS

Based on the experimental findings, [(Acetylamino)methyl]phosphonic acid (IN-EY252), metabolite of glyphosate, was negative for gene mutation in bacteria in the Ames standard plate test in the presence and absence of metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, [(Acetylamino)methyl]phosphonic acid was negative for gene mutation in bacteria (*S. typhimurium* TA 100, TA 98, TA 1535 and TA 1537 and *E. coli* WP2 uvrA) with and without metabolic activation.

The study was conducted under GLP conditions and in accordance with OECD guideline 471 (1997). There were no deviations from the guideline. The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/035

1. Information on the study

Data point	CA 5.8.1
Report author	[redacted]
Report year	2007
Report title	IN-EY252*: In vitro* Mammalian Chromosome Aberration Test in Human Peripheral Blood Lymphocytes
Report No	AB47BT.341.BTL
Document No	DuPont-22225
Guidelines followed in study	OECD 473 (1997), US EPA OPPTS 870.5375 (1998), EC Commission Directive 2000/32/EC Annex 4A-B10 (2000), JMAFF 12-NouSan-8147 (2000 and 2001)
Deviations from current test guideline	Only 200 cells in metaphase were evaluated, whereas the currently valid OECD 473 (2016) recommends the evaluation of 300 metaphase cells per condition.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

[(Acetylamino)methyl]phosphonic acid (IN-EY252, batch: IN-EY252-001, purity: 76 %) was tested in a mammalian chromosome aberration test in peripheral human lymphocytes *in vitro* for its potential to induce structural and numerical chromosome aberrations in the presence and absence of metabolic activation (rat liver S9 fraction).

Concentrations for the cytogenicity study were selected based on the results of a preliminary toxicity test, in which no cytotoxicity was observed up to 1530 µg/mL (corresponding to 10 mM) in the presence and absence of S9 mix. Duplicate cultures were exposed to the test item, solvent (water) or positive control (mitomycin C in the absence of S9 mix and cyclophosphamide in the presence of S9 mix) in the presence and absence of metabolic activation. Test item concentrations ranged from 191.25 to 1530 µg/mL.

The cells were exposed for 4 hours in the presence and absence of S9 mix and for 20 hours in the absence of S9 mix. Cells of the 4-hour exposure period were washed with calcium and magnesium-free phosphate buffered saline following treatment and re-incubated in culture medium for the remaining 16 hours of incubation. All cultures were sampled 20 hours after start of exposure and chromosome preparations were made.

A total of 200 metaphase cells per condition were scored for structural and numerical chromosome aberrations. Cytotoxicity was evaluated as mitotic index and assessed for 500 cells per culture.

Precipitation of the test substance in vehicle or culture medium, or cytotoxicity, evident as a ≥ 50 % reduction in the mitotic index were not observed for any treatment schedule or any concentration, neither in the presence, nor in the absence of S9 mix.

There was no statistically significant increase in the number of cells with structural or numerical chromosomal aberrations observed for any treatment schedule, neither in the presence nor in the absence of metabolic activation. The percentage of aberrant cells in the test substance-treated groups was comparable to those of solvent controls at any dose level.

The positive and vehicle controls fulfilled the criteria for a valid test and demonstrated the functionality of the metabolic activation system and the validity of the test.
Under the conditions of the test, [(Acetylamino)methyl]phosphonic acid, metabolite of glyphosate, did not induce chromosomal aberrations in human peripheral lymphocytes *in vitro*, neither in the presence nor in the absence of metabolic activation.

Materials and methods

A. MATERIALS

1. Test material: [(Acetylamino)methyl]phosphonic acid (metabolite of glyphosate)

Identification: IN-EY252
Description: White powder
Lot/Batch number: IN-EY252-001
Purity: 76 %
Stability of test compound: The stability of the test item at storage conditions (at room temperature in the dark with dessicant) was guaranteed until the expiry date 25 Apr 2009. The stability of the test item in solvent was confirmed by analytical methods.
Solvent (vehicle) used: Water

2. Control material:

Negative control: The negative control was actually the solvent control.
Solvent (vehicle) control: Water
Positive control: - S9 mix: Mitomycin C (MMC), 0.6 µg/mL for the 4-hour treatment and 0.3 µg/mL for the 20-hour treatment
+ S9 mix: Cyclophosphamide (CP), 20 µg/mL

3. Metabolic activation:

S9 mix was purchased from [redacted] (Lot no. 2074) and each batch was assayed for sterility and it's ability to metabolise 2-aminoanthracene and 7,12-dimethyl-benzanthracene to mutagens in *Salmonella typhimurium* strain TA 100.
Immediately prior to use, S9 was thawed and mixed with co-factors as follows:

S9 mix component	Concentration	Unit
KCl	6	mM
NADPH-generating system		
Glucose 6-phosphate	1	mM
NADP	1	mM
$MgCl_2$	2	mM
S9	2	% (v/v)

4. Test organism:

Human peripheral blood lymphocytes were obtained from a healthy, non-smoking, 25-year old female (preliminary cytotoxicity test) and from a healthy, non-smoking 30-year old male (main cytogenicity test) and collected in heparinised vessels.

5. Cell culture media:

Medium: RPMI 1640 medium, supplemented with 100 U/mL penicillin,

Incubation:	100 µg/mL streptomycin and 2 mM L-glutamine *Cultures were incubated at 37 ± 1 °C in a humidified atmosphere of 5 ± 1 % CO_2.*
Cell culture establishment prior to exposure:	*0.6 mL of heparinised blood was cultured with 9.4 mL culture medium and 0.1 % phytohaemagglutinin for 44 - 48 hours prior to treatment.*

6. Test concentrations and number of replicates:

(c) Preliminary cytotoxicity assay

Metabolic activation	Duration of exposure (Fixation time)	Concentrations§	Replicates
- S9 mix	4 h (20 h)	0.153, 0.459, 1.53, 4.59, 15.3, 45.9, 153, 459 and 1530# µg/mL	Single culture
- S9 mix	20 h (20 h)	0.153, 0.459, 1.53, 4.59, 15.3, 45.9, 153, 459 and 1530# µg/mL	Single culture
+ S9 mix	4 h (20 h)	0.153, 0.459, 1.53, 4.59, 15.3, 45.9, 153, 459 and 1530# µg/mL	Single culture

#: highest concentration, corresponding to 10 mM
§: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 1.45.

(d) Main cytogenicity test:

Metabolic activation	Duration of exposure (Fixation time)	Concentrations§	Replicates
- S9 mix	4 h (20 h)	191.25, 382.5*, 765* and 1530*# µg/mL	Duplicate
- S9 mix	20 h (20 h)	191.25, 382.5*, 765* and 1530*# µg/mL	Duplicate
+ S9 mix	4 h (20 h)	191.25, 382.5*, 765* and 1530*# µg/mL	Duplicate

* Samples analysed for chromosomal aberrations

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 08 Mar – 17 Apr 2007
Finalisation date: 18 Jun 2007

2. Preliminary cytotoxicity test:
In a preliminary cytotoxicity test, human peripheral lymphocytes were treated with the test item at concentrations in the range of 0.153 – 1530 µg/mL in the presence and absence of S9 mix. The test was conducted under the same conditions as in the main cytogenicity experiment. A single cell culture per condition was exposed for 4 hours in the presence and absence of S9 mix and for 20 hours in the absence of S9 mix. All cells were harvested 20 hours after start of exposure. Two hours prior to harvest, 0.1 µg/mL colcemid was added to the cultures to arrest cells in metaphase. At harvest, the cells were collected by centrifugation, treated with hypotonic potassium chloride (75 mM), fixed and stained. The number of cells in mitosis was determined per 500 cells scored in order to evaluate the test item effect on mitotic index.

3. Main cytogenicity test:

Treatment:	Following cell culture establishment, duplicate cultures per condition were exposed to the test item, solvent (water) or positive control (mitomycin C in the absence of S9 mix and cyclophosphamide in the presence of S9 mix) in the presence and absence of metabolic activation. The cells were exposed for 4 hours in the presence and absence of S9 mix and for 20 hours in the absence of S9 mix. Cells of the 4-hour exposure period were washed with calcium and magnesium-free phosphate buffered saline (CMF-PBS) following treatment, re-fed with culture medium and returned to the incubator for 16 further hours. For all conditions, chromosome preparations were made 20 hours after start of exposure.
Spindle inhibition:	During the last 2 hours of the culture period, cell division was arrested by addition of 0.1 µg/mL colchicine each culture.
Cell harvest:	The cell cultures were harvested by centrifugation, the pellets were re-suspended in 75 mM potassium chloride and swollen for 20 minutes at 37 ± 1 °C. Afterwards, the cells were gently mixed and approx. 0.5 mL of fixative (methanol : glacial acetic acid, 3 : 1, v/v) was added to each tube. Cells were collected by centrifugation, washed twice in fixative and stored in fixative until preparation.
Slide preparation:	Fixed cells were centrifuged and re-suspended in 0.1 – 0.3 mL of the supernatant fixative above the cell pellet. One or two drops of cell suspension were placed on glass slides and allowed to air-dry. Dried slides were coded, stained with 5 % Giemsa, air-dried and permanently mounted.
Metaphase analysis:	A total number of 200 metaphase cells per condition (100 per duplicate treatment condition) were examined by microscopy. Only metaphase cells with 46 centromers were examined. In case the percentage of aberrant cells reached a significant level (≥ 10 %) before 100 cells were scored, less metaphases were investigated. Chromatide-type and chromosome-type aberrations were recorded, including breaks, exchange figures and complex re-arragements. In addition, pulverised chromosomes and cells and severely damaged cells were recorded. The percentage of polyploidy and endoreduplicated cells was evaluated per 100 cells.
Cytotoxicity:	The mitotic index of each culture was calculated based on the number of cells in metaphase observed per 500 cells scored.

4. Statistics

Statistical analysis of the percent aberrant cells was performed using the Fisher's Exact test. Fisher's Exact test was used to compare pairwise the percent aberrant cells of each treatment group with that of the solvent control. In the event of a positive Fisher's Exact test at any test substance dose level, the Cochran-Armitage test was used to measure dose-responsiveness.

5. Acceptance criteria

The chromosome aberration test was considered acceptable if the following criteria were met:

- The frequency of cells with structural chromosome aberrations in the vehicle control was within the laboratories historical range.
- The percentage of cells with chromosome aberrations in the positive control was statistically increased ($p \leq 0.05$) relative to the solvent control.

6. Evaluation criteria

A test substance was considered positive (clastogenic) in the chromosome aberration test if the following criteria were met:

- The percentage of cells with aberrations was increased in a dose-related manner with one or more concentrations being statistically elevated relative to the solvent control group ($p \leq 0.5$).
- Values that were statistically significant but did not exceed the range of historical solvent control data were judged as not biologically significant.

A test substance not demonstrating a statistically significant increase in aberrations was concluded to be negative.

II. RESULTS AND DISCUSSION

E. ANALYTCAL DETERMINATIONS

Analytical determinations of the test substance in the solvent were performed for the formulations 1.9125, 3.825 and 15.30 mg/mL. The concentrations determined were 111.9 %, 110.8 % and 107.8 % of the nominal concentration, respectively, which were within the accepted range of 85 – 115 % of the target concentration. The formulations proved to be stable for 5 hours at room temperature.

F. CYTOTOXICITY

Preliminary cytotoxicity test

In the preliminary cytotoxicity test, substantial cytotoxicity (at least 50 % reduction in mitotic index when compared to the solvent control) was not observed for any treatment schedule, up to the highest tested concentration of 1530 µg/mL, neither in the presence, nor in the absence of S9 mix.

The osmolality of the highest test substance concentration in treatment medium did not exceed the osmolality of the solvent by more than 20 % and was therefore considered acceptable. The pH of the highest test substance concentration was 7.0.

Based on these results, 1530 µg/mL was chosen as the highest test item concentration for the main cytogenicity study.

Main mutagenicity test

In the main mutagenicity test, cytotoxicity evident as a reduced mitotic index of ≥ 50 % was not observed for any treatment schedule or any concentration, neither in the presence, nor in the absence of S9 mix.

G. SOLUBILITY

Precipitation of the test item in solvent or culture medium was not observed for any treatment schedule, neither in the presence, nor in the absence of metabolic activation.

H. CYTOGENICITY

There was no statistically significant increase in the number of cells with structural or numerical chromosomal aberrations observed for any treatment schedule, neither in the presence nor in the absence of metabolic activation. The percentage of aberrant cells in the test substance-treated groups was comparable to those of solvent controls at any dose level. The number of average aberrations per cell observed for the highest test item concentration after 4 hours of exposure in the presence of S9 mix (0.005 ± 0.071) was increased when compared to those of the solvent controls (0.0 ± 0.0). The value observed for the test item is explained by a single chromosome aberration of gap-type, which is not included in the assessment of total aberration frequency. As the percentage of structural aberrant cells was within the range of historical control data, the observation was considered not relevant. The frequency of chromosomal aberrations observed for the solvent and positive controls was within the range of the laboratory's historical control data. The positive controls (mitomycin C without S9 mix and cyclophosphamide with S9 mix) induced a statistically significant increase in the number of structural chromosome aberrations,

demonstrating the functionality of the metabolic activation system and proving the validity of the test.

% of aberrant cells: numerical includes polyploidy and endoreduplicated cells; structural excludes cells with only gaps
** $p \leq 0.01$ using Fisher's Exact Test

III. CONCLUSIONS

Based on the experimental findings there is no evidence for an induction of structural or numerical chromosome aberrations by IN-EY252, metabolite of glyphosate, in peripheral human lymphocytes, neither in the presence nor in the absence of metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, [(Acetylamino)methyl]phosphonic acid was negative for cytogenicity (chromosome aberrations *in vitro*) in peripheral human lymphocytes with and without metabolic activation.

The test was performed under GLP conditions and in accordance with OECD guideline 473 (1997).

There were only minor deviations when compared to OECD 473 (2016). The number of metaphases investigated was only 200, which was the number to be investigated recommended by the previous OCED 473 (1997). The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/036

1. Information on the study

Data point	CA 5.8.1
Report author	[redacted]
Report year	2007
Report title	IN-EY252: In Vitro Mammalian Cell Gene Mutation Test (CHO/HGPRT)
Report No	DuPont-22224
Document No	-
Guidelines followed in study	OECD 476 (1997), US EPA OPPTS 870.5300, EC Commission Directive 2000/32/EC Annex 4E-B17 (2000), JMAFF (1985)

Deviations from current test guideline	The newly introduced cytotoxicity parameter RS (relative survival) in OECD 476 (2016) and the adjusted cloning efficiency were not re-calculated, since no data on the number of cells after treatment were provided. In the current study, cytotoxicity was evaluated based on cloning efficiency after treatment (CE_1, survival) and after selection (CE_2, viability), in accordance with the previous guideline version. Historical control data for the negative control were reported without 95 % control limits. In addition, acceptability and evaluation criteria specified in the study report were inconsistent with those specified in the current guideline.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

[(Acetylamino)methyl]phosphonic acid (IN-EY252, batch: IN-EY252-002, purity: 72 %) was tested *in vitro* for its ability to induce forward mutations in mammalian cells by assessing the mutation of the HPRT locus in Chinese hamster ovary (CHO K_1) cells. Duplicate cultures were exposed to the test item, solvent (water) and positive controls (ethylmethane sulfonate for cultures without S9 mix and benzo(a)pyrene for cultures with S9 mix) in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). Based on the results of a preliminary toxicity test, in which no substantial cytotoxicity was observed up to 1531 µg/mL (corresponding to 10 mM), the concentrations for the main mutagenicity study were selected. [(Acetylamino)methyl]phosphonic acid concentrations in the range of 100 – 1531 µg/mL were applied. After 5 hours of exposure with and without S9 mix, the cells were incubated for 7 days to allow expression of the mutant phenotype. The expression period was followed by a selection period, in which the cells were cultivated in 6-thioguanidine-enriched medium for 10 days. Cytotoxicity was assessed as relative survival and relative viability after the expression and selection period, respectively.

There was no precipitation of the test item in solvent and in culture medium, neither in the presence nor absence of S9 mix. Substantial cytotoxicity was not observed for any condition at any concentration. The relative cloning efficiency at the highest concentration of 1531 µg/mL was 67 % without S9 mix and 83 % with S9 mix.

There was no increase in the number of mutant colonies upon treatment with the test substance, neither in the presence nor in the absence of metabolic activation. For all conditions and at all dose levels, mutant frequencies were below the minimum value for a positive response.

Mutant frequencies of the control cultures remained within the range of the laboratories historical control data. The positive control mutagens ethylmethane sulfonate and benzo(a)pyrene induced mutant frequencies that were at least 3-fold above those of vehicle controls, demonstrating the functionality of the S9 mix and the sensitivity of the test.

Under the conditions of the test, there was no evidence for gene mutation in mammalian cells *in vitro*, neither in the presence nor in the absence of metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: [(Acetylamino)methyl]phosphonic acid

Identification: IN-EY252
Description: White solid
Lot/Batch number: IN-EY252-002

Purity:	72 %
Stability of test compound:	The stability of the test item at storage conditions (with a desiccator) was guaranteed until the expiry date 13 Apr 2010. The stability of the test substance in vehicle was confirmed by analytical methods.

2. Control material:

Negative control:	The negative control was actually the solvent control.
Solvent (vehicle) control:	Water
Positive control:	- S9 mix: Ethylmethane sulfonate (EMS), 0.2 µL/mL in DMSO + S9 mix Benzo(a)pyrene (BaP), 4 µg/mL in DMSO

3. Metabolic activation:

S9 mix was purchased from [redacted]. ([redacted]). The liver homogenate was produced from the livers of male Sprague-Dawley rats that were induced with Aroclor 1254. Immediately prior to use the S9 liver homogenate was thawed and mixed with co-factors as follows:

S9 mix component	Concentration	Unit
Sodium phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	10	% (v/v)

4. Test organism:

Chinese hamster ovary (CHO-K_1) cells were obtained from American Type Culture Collection (ATCC) in Manassas, Virginia, USA. The cell stocks were stored in liquid nitrogen and routinely tested for mycoplasma contamination. Cells used in the mutation assay were within three to four subpassages from cleansing in pre-treatment medium supplemented with hypoxanthine, aminopterin and thymidine (HAT) in order to assure karyotypic stability.

5. Cell culture media:

Pre-treatment medium (HAT medium):	Ham's F12 medium supplemented with hypoxanthine, aminopterin and thymidine
Cultivation medium (F12FBS5-Hx):	Ham's F12 medium, supplemented with 5 % dialysed fetal bovine serum, 100 U/mL penicillin and 100 µg/mL streptomycin
Treatment medium (± S9):	*Cultivation medium (F12FBS5-Hx)*
Selection medium:	Cultivation medium (F12FBS5-Hx) supplemented with 10 µM 6-thioguanidine (6TG)
Incubation:	*At 37.5 ± 2 °C in a humidified atmosphere of 5 ± 2 % CO_2*

6. Locus examined: Hypoxanthin guanine phosphoribosyltransferase (HGPRT)

7. Test concentrations and number of replicates:

(c) Preliminary cytotoxicity and mutagenicity test:

Metabolic activation	Duration of exposure	Concentrations§	Replicates
± S9 mix	5 h	5, 10, 25, 50, 100, 250, 500, 1000 and 1531 µg/mL	Triplicate plates from a single culture

§: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 1.389.

(d) Main gene mutation test:

Metabolic activation	Duration of exposure	Concentrations§	Replicates
± S9 mix	5 h	100, 250, 500, 1000 and 1531 µg/mL	Triplicate plates from duplicate cultures

§: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 1.389.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 30 May – 12 Sep 2007
Finalisation date: 25 Sep 2007

2. Preliminary cytotoxicity and mutagenicity test:
A preliminary test was performed to identify suitable dose levels for the main mutagenicity study. Cell cultures were established identically to the performance in the main mutagenicity test described below. The cells were exposed to nine test substance concentrations in the range of 5 – 1531 µg/mL for 5 hours in the presence and absence of S9 mix at 37 ± 2 °C. The highest concentration was equivalent to a 10 mM concentration. Following exposure, the cells were washed with Hank's Balanced Salt Solution (HBSS), re-incubated in fresh culture medium for approx. 20 hours, harvested and plated for determination of cell survival (cloning efficiency 1). After incubation for 8 days, the formed colonies were fixed, stained and counted.
Based on the results of the preliminary test, the test item concentrations for the main mutagenicity test were selected.

3. Main mutation assay:
Pre-treatment of cells:
For each test group, 5 x 10^5 cells were seeded into 25 cm^2 flasks and incubated for 16 - 24 hours prior to treatment.

Treatment:
On the day of treatment, the medium was exchanged. For treatment in the presence of S9 mix, 20 % of the medium were replaced by S9 mix. Duplicate cultures were exposed to the test item, vehicle (water) and positive controls (0.2 µL/mL ethylmethane sulfonate without S9 mix and 4 µg/mL benzo(a)pyrene with S9 mix) for 5 hours in the presence and absence of metabolic activation at 37 ± 2 °C. Test item concentrations ranged from 100 – 1531 µg/mL. Following exposure, the cells were washed with Hank's Buffered Salt Solution (HBSS) and the culturing was continued for another 18 – 24 hours. After the incubation period, the cells were trypsinised and counted. Triplicates of 100 cells/ 60 mm dish were seeded for the determination of survival (cloning efficiency 1) and duplicate cultures with ≤ 10^6 cells/ 100 mm dish were seeded for the expression of the mutant phenotype.

Expression period:
After treatment, duplicate cultures with ≤ 10^6 cells/ 100 mm dish were seeded and sub-cultured at 2 - 3

day intervals for a 7-day expression period. After the expression period, each culture was divided. Triplicates of 100 cells/ 60 mm dish were seeded for the determination of viability (cloning efficiency 2) and five culture dishes with 2 x 10^5 cells/ 100 mm dish were seeded for the selection of mutants.

Selection period:
For the selection of mutants, five culture dishes with 2 x 10^5 cells/ 100 mm dish were seeded in medium enriched with 10 µM 6-thioguanidine (selection medium). After an incubation period of 10 days, the colonies were fixed, stained and counted.

4. Cytotoxicity:

Cloning efficiency CE_1 (survival)
The survival (cloning efficiency 1) of [(Acetylamino)methyl]phosphonic acid-treated cells relative to solvent controls was determined in parallel to the mutagenicity test. At the end of the exposure period, a sample of each cell culture was collected to assess survival of the cells. Triplicates of 100 cells/60 mm dish were seeded and incubated for 7 days. Afterwards, the colonies were fixed, stained and counted.

Cloning efficiency CE_2 (viability)
The viability (cloning efficiency 2) was determined in parallel to the selection of mutants. After the expression period, triplicates of 100 cells/60 mm dish were seeded in medium without 6-thioguanine to assess cell viability. After an incubation period of 10 days, the developed colonies were fixed, stained and counted.

5. Evaluation:

Cytotoxicity (cloning efficiency CE)
The number of colonies divided by the number of cells plated was calculated for each sample. The absolute cloning efficiency was determined for each test group, as well as the relative cloning efficiency in comparison to the solvent control group.

CE_1 (survival)
The cytotoxicity of the test substance after the exposure period was determined for each test group and is indicated as absolute and relative cloning efficiency (CE_1 and RCE_1, respectively).

CE_2 (viability)
The cytotoxicity of the test substance at the end of the expression period was determined for each test group and is given as absolute and relative cloning efficiency (CE_2 and RCE_2, respectively).

The cloning efficiency (CE, %) was calculated for each test group as follows:

$$\mathrm{CE_{absolute}} = \frac{\text{Total number of colonies}}{\text{Total number of cells plated}} \times 100$$

$$\mathrm{RCE_x} = \frac{\mathrm{CE_{absolute}} \text{ of the test group}}{\mathrm{CE_{absolute}} \text{ of the vehicle control group}} \times 100$$

Mutant frequency (MF)
The cloning efficiency of mutant colonies in selective medium divided by the cloning efficiency in non-selective medium measured for the same culture at the time of selection was calculated for each sample.

Uncorrected mutant frequency:
The uncorrected mutant frequency (MF_{uncorr}) was calculated for each test group as follows:

$$\text{MF uncorrected} = \frac{\text{Total number of mutant colonies}}{\text{Number of seeded cells}} \times 10^6$$

Corrected mutant frequency
The corrected mutation frequency (MF_{corr}) was calculated regarding the values of CE_2:

$$\text{MF corrected} = \frac{\text{MF uncorrected}}{CE_2} \times 100$$

6. Statistics:
Statistical analysis was not performed.

7. Acceptance criteria:
The test was considered valid if the following criteria were met:

- The cloning efficiency of the vehicle control was > 50 % with a spontaneous mutant frequency within the range of the laboratories historical control data.
- The mutant frequency of the positive control was at least 3-fold as compared to the concurrent vehicle control and exceeded 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data).
- At least 4 analysable concentrations showing mutants were required for evaluation.

8. 8. Evaluation criteria:
A test item was judged positive for gene mutation in mammalian cells if the following criteria were met:

- A mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at 2 or more consecutive concentrations of the test substance when compared to the solvent control.
- The observed increase in mutant frequency was accompanied by a concentration-related increase.
- A mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at the highest concentration only.

The test item was judged equivocal if a mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at any dose level other than the highest concentration.

The test item was judged negative for gene mutation in mammalian cells if a mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was not observed at any dose level.

II. RESULTS AND DISCUSSION

1. ANALYTICAL DETERMINATIONS

Analytical determinations were performed using a high performance liquid chromatography (HPLC) with UV/Vis detection. The test item formulations were ± 7 % (preliminary toxicity test) and ± 5 % (main mutation assay) of the nominal concentrations and therefore within the acceptable range (± 10 % of the nominal concentration). There was no test substance in the 0 mg/mL sample. Stability of the test item in vehicle was confirmed for 23 hours at room temperature.

2. CYTOTOXICITY

In the preliminary cytotoxicity test, no cytotoxicity, evident as a cloning efficiency of ≤ 50 %, was observed. The relative cloning efficiency at the highest test item concentration (1531 µg/mL) was 59 % in the absence of S9 mix and 308 % in the presence of S9 mix. Osmolality and pH measurements of test substance in medium at 1531 µg/mL were found to be within an acceptable range (≤ 20 %). Based on these findings, the concentrations for the main mutagenicity study were selected to be in the range of 100 – 1531 µg/mL,

corresponding to 0.65 – 10 mM.
In the main mutagenicity experiment, no substantial cytotoxicity was observed at any dose level, neither in the presence nor absence of S9 mix.

3. SOLUBILITY

There was no precipitation observed up to the highest concentration tested, neither in the presence, nor absence of metabolic activation.

4. MUTANT FREQUENCY

In a first trial, a high spontaneous mutant frequency was observed for the solvent controls in both, cultures with and without S9 mix (data not shown). The test was therefore considered invalid and repeated.
In the second trial, there was no increase in the number of mutant colonies upon treatment with [(Acetylamino)methyl]phosphonic acid, neither in the presence nor in the absence of metabolic activation. For all conditions and at all dose levels, mutant frequencies were below 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) and no dose-response relationship was evident.
Mutant frequencies of the solvent control cultures remained within the range of the laboratory's historical control data. The positive control mutagens ethylmethane sulfonate and benzo(a)pyrene induced mutant frequencies that were at least 3-fold above those of vehicle controls, demonstrating the functionality of the S9 mix and the sensitivity of the test.

HCD: Historical control data, generated in the laboratory from 1989 - 2005

III. CONCLUSIONS

Based on the experimental findings and under the conditions of the test, [(Acetylamino)methyl]phosphonic acid did not induce gene mutations in the HGPRT locus of CHO-K$_1$ cells, neither in the presence nor in the absence of metabolic activation and is therefore considered negative for mutagenicity in mammalian cells *in vitro*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, [(Acetylamino)methyl]phosphonic acid was negative for mutagenicity at the HGPRT locus in CHO-K$_1$ cells with and without metabolic activation.
The study was conducted in compliance with GLP and according to OECD guideline 476 (1997). There were only minor deviations when compared to OECD 476 (2016), which were considered to not compromise the validity of the study. The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/037

1. Information on the study

Data point	CA 5.8.1
Report author	[redacted]
Report year	2007
Report title	IN-EY252: Mouse Bone Marrow Micronucleus Test
Report No	[redacted]-22226
Document No	NA
Guidelines followed in study	OECD 474 (1997), US EPA OPPTS 870.5395 (1998), EEC Directive 2000/32/EC B12 (2000), JMAFF 12 Nousan (2000)
Deviations from current	According to the current guideline OECD 474 (2016), at least 4000

test guideline	polychromatic erythrocytes per animal should be evaluated for the presence of micronuclei. However, in the present study only 2000 polychromatic erythrocytes were evaluated, since that was required in the previous OECD guideline (1997). Bone marrow exposure, indicated by a reduced polychromatic to normochromatic erythrocyte ratio, was not confirmed and there was no systemic toxicity observed, but dose levels included limit concentrations specified in the current guideline. In addition, no 95 % control limits were reported for the historical control data.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

[(Acetylamino)methyl]phosphonic acid (IN-EY252, batch: IN-EY252-002, purity: 72 %) was tested for its potential to induce micronuclei in male and female Crl:CD1 (ICR) mice. Based on the results of a preliminary toxicity study, dose levels for micronucleus tests were selected. Groups of 5 mice per sex per dose level were administered a single dose of 500, 1000 or 2000 mg/kg bw by oral gavage. For the high dose group, 2 additional mice/sex/sampling time point were treated and served as backup (scoring of micronuclei was not performed). Similar constituted groups received the vehicle (deionised water) or the positive control (30 mg/kg bw cyclophosphamide).

Body weights of the animals were collected prior to treatment and 24 and 48 hours post dosing. The animals were observed for clinical signs of toxicity and mortality 1, 3.5, 24 and 48 hours after treatment. About 24 and 48 hours after dosing, the animals of the test item-treated and vehicle control groups were sacrificed and bone marrow smears were prepared. For animals of the positive control group, bone marrow was sampled 24 hours after dosing. For each animal, 2000 polychromatic erythrocytes (PCE) were scored for the presence of micronuclei. In addition, the proportion of PCE among 1000 erythrocytes, expressed as ratio PCE / normochromatic erythrocytes (NCE) was determined.

Treatment with [(Acetylamino)methyl]phosphonic acid induced no mortality in the animals and no clinical signs of toxicity were noted at any dose level. In addition, body weight and body weight gain were not affected in any dose group at any sampling time point. Based on the ratio of PCE / NCE, there was no evidence for bone marrow toxicity.

There was no statistically significant and no biologically relevant increase in the frequency of micronucleated PCE (mPCE) when compared to vehicle control animals at any dose level and for any sampling time.

Incidences of mPCE in solvent and positive control animals were within the range of the laboratory's historical control data and demonstrated the validity and sensitivity of the test system.

Based on the experimental findings of the present study and under the conditions of the test, the test item did not induce micronuclei in the bone marrow of male and female mice *in vivo*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	[(Acetylamino)methyl]phosphonic acid
Identification:	IN-EY252
Description:	White solid
Lot/Batch #:	IN-EY252-002

Purity:	72 %
Stability of test compound:	The stability of the test item at storage conditions (with a desiccator) was guaranteed until the expiry date 13 Apr 2010. The stability of the test substance in vehicle was confirmed by analytical methods.
Solvent (vehicle) used:	Deionised water

2. Control materials

Solvent (vehicle) control:	Deionised water
Positive control:	Cyclophosphamide, 30 mg/kg bw in deionised water

3. Test animals:

Species:	Mouse
Strain:	Crl:CD1 (ICR)
Sex:	Male and female
Source:	[redacted]
Age at study initiation:	Approx. 7 weeks
Mean weight at dosing:	28.2 – 37.5 g (males) and 21.4 – 27.6 g (females)
Acclimation period:	At least 5 days
Diet/Food:	LLC Certified Rodent LabDiet® 5002 (PMI® Nutrition International), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually

4. Environmental conditions:

Temperature:	18 - 26 °C
Humidity:	30 - 70 %
Air changes:	Not specified
Photoperiod:	12-hour light and dark cycle

5. Test concentrations and treatment groups:

a) Preliminary toxicity study

Dose levels:	2000 mg/kg bw
Concentrations:	Not specified
Dose volume:	Not specified
Number of animals:	3 males
Route of administration:	Oral gavage

b) Main micronucleus test

Dose levels:	500, 1000 and 2000 mg/kg bw[36]
Concentrations:	50, 100 and 200 mg/mL
Dose volume:	10 mL/kg bw
Number of animals:	5/sex/group and additional 2/sex/sampling time point as backup for the high dose group (additional animals were not used for scoring of micronuclei)
Route of administration:	Oral gavage

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 22 May – 23 Jul 2007
Finalisation date: 07 Sep 2007

2. Animal assignment and treatment:

Preliminary toxicity study:
In a preliminary range-finding test 3 male animals were administered a single dose of 2000 mg/kg bw by oral gavage. The animals were observed for clinical signs of toxicity and mortality immediately after dosing and daily for two days. Based on the results of the preliminary toxicity study, the dose levels for the micronucleus test were selected.

Main micronucleus test:
Groups of 5 mice per sex and dose level were administered a single dose of 500, 1000 or 2000 mg/kg bw. For the high dose group, 2 additional mice/sex/sampling time point were treated and served as backup (scoring of micronuclei was not performed). The test substance was dissolved in deionised water and administered by oral gavage at a constant dosage volume of 10 mL/kg bw. Similar constituted groups of 5 mice/sex received the vehicle (deionised water) or the positive control (30 mg/kg bw cyclophosphamide).
Individual body weights were collected prior to treatment and 24 and 48 hours post dosing. The animals were observed for clinical signs of toxicity and mortality 1, 3 - 5, 24 and 48 hours after treatment. About 24 and 48 hours after dosing, the animals of the test item-treated and control groups were sacrificed by CO_2 asphyxiation and bone marrow samples were generated. Animals of the positive control group were sacrificed 24 hours after administration.

3. Slide preparation:

After sacrifice, both femurs of the animals were removed, and marrow was aspirated with the aid of a syringe containing fetal bovine serum (FBS). After centrifugation, the pellet was re-suspended in FBS and a small drop was placed on pre-cleaned microscope slides. Smears were made using a Mini Prep® blood smearing instrument. At least 3 slides were prepared for each animal. The slides were air-dried, fixed in methanol and stained in acridine orange.

4. Slide evaluation:

[36]: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor.

Slides were coded and evaluated by fluorescent microscopy. For each animal, 2000 polychromatic erythrocytes (PCE) were scored for the presence of micronuclei. Cells containing more than one micronucleus were scored as single micronucleated PCE (mPCE). In addition, the proportion of PCE among 1000 erythrocytes, expressed as ratio PCE / normochromatic erythrocytes (NCE) was determined.
If no increase in the incidence of mPCE was observed at the 24-hour sampling time point at any dose level, slide evaluation for the 48-hour sampling was performed for animals of the high dose and control group only.

5. Statistics:

Data for the amount of micronucleated polychromatic erythrocytes (mPCE) among 2000 erythrocytes and the ratio of PCE among normochromatic erythrocytes (NCE) were transformed prior to analysis using an arcsine square root or Freeman-Tukey function. Transformed data for PCE and MNPCE frequencies were analyzed separately for normality of distribution and equal variance using the Shapiro-Wilk and Levene's tests, respectively.
For those data that were normally distributed and had equal variance, parametric statistics (e.g. analysis of variace (ANOVA) and Dunnett's test) were performed using the transformed data. For those data that were normally distributed but had unequal variance, a robust ANOVA and unequal-variance Dunnett test was done. For those data that were not normally distributed, nonparametric statistics (e.g., Kruskal-Wallis and Dunn's tests) utilizing non-transformed data was performed. The individual animal was considered the experimental unit. All data analyses was one-tailed and conducted at a significance level of 5 %.

6. Acceptance criteria:

The study was considered valid if the following criteria were met:

- In the vehicle control group, the mean frequency of micronucleated polychromatic erythrocytes (mPCE) was within the range of the laboratories historical control range.
- The positive control induced a statistically significant increase in the frequency of mPCE as compared to the vehicle control group.

7. Evaluation criteria:

The test item was considered positive if the following criteria were met:

- The group mean number of micronucleated polychromatic erythrocytes (mPCE) was statistically significantly increased at one or more concentrations when compared to the concurrent vehicle control value.
- An accompanying statistically significant dose-response increase in mPCE was observed.

The test item was considered negative if the following criteria were met:

- There was no statistically significant, dose-related increase in the group mean mPCE above the concurrent vehicle control at any concentration.
- The mPCE values were within reasonable limits of the recent (past 3 years) laboratory historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The dosing formulations were analysed by high performance liquid chromatography (HPLC) and UV/Vis detection. The data indicated that the achieved concentration of test substance in vehicle was ± 5 % of the nominal concentration, which was considered acceptable. Stability of the test substance in vehicle was confirmed for 5 hours at room temperature.

B. PRELIMINARY TOXICITY STUDY

Data on clinical signs of toxicity in the preliminary toxicity study were not included.

C. MAIN MICRONUCLEUS TEST

Systemic toxicity:

Mortality:

No mortality occurred.

Clinical signs of toxicity:

Clinical signs of toxicity were not observed at any time point or at any dose level.

Body weight and body weight gain:

There were no significant changes in body weight or body weight gain in either male or female animals of any test group.

Evaluation of bone marrow slides:

Upon treatment with the test substance at any dose level and sampling time point, the ratio of polychromatic (PCE) to normochromatic erythrocytes (NCE) was not affected, indicating that no bone marrow toxicity was evident.

In addition, there was no statistically significant and no biologically relevant increase in the frequency of mPCE when compared to vehicle control animals at any dose level and for any sampling time.

Incidences of mPCE in solvent and positive control animals stayed within the range of the laboratory's historical control data and proved the validity and sensitivity of the test system.

III. CONCLUSIONS

Based on the experimental findings [(Acetylamino)methyl]phosphonic acid did not induce micronuclei in bone marrow of male and female mice and is therefore considered negative for clastogenicity *in vivo*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, [(Acetylamino)methyl]phosphonic acid was negative for clastogenic and aneugenic effects in the bone marrow of male and female Crl:CD1 (ICR) mice *in vivo*.
The study was conducted under GLP conditions and in accordance with OECD guideline 474 (1997). Only 2000 polychromatic erythrocytes were evaluated, since that was required in the previous OECD guideline (1997). Bone marrow toxicity, indicated by a reduced polychromatic to normochromatic erythrocyte ratio, or systemic toxicity were not observed. However, the test was performed at limit dose levels in line with the current guideline. The deviations were considered to be of minor degree and do not compromise the validity of the study. The study is therefore considered valid.

Assessment and conclusion by RMS:

Studies with N-acetyl glyphosate

The metabolite N-acetyl glyphosate was investigated for metabolism/pharmacokinetics, acute oral toxicity, subchronic toxicity and mutagenicity. All studies presented are submitted on EU level for the first time.

In an ADME study in male rats, it was shown, that N-acetyl glyphosate is rapidly absorbed from the gastrointestinal tract. The mean maximum concentrations (Cmax) in blood and plasma were 2.93 and 5.31 µg equivalents/g at 1 and 2 hours post-dose, respectively. Radioactivity was eliminated from blood and plasma with half-life values of 20.1 and 15.6 h, respectively.
Approx. 66 % of the total radioactivity was excreted in urine and 26 % in faeces. Over 90 % of the radioactivity was eliminated within 48 h post-dose. No metabolites were detected in plasma and urine.
A metabolite found at less than 0.25 % of the administered radioactivity in faeces was glyphosate, which was formed by N-deacetylation ([redacted] 2004, CA 5.8.1/038). This is further confirmed, by metabolite analysis conducted in a 90-day study in rats ([redacted], 2007, CA 5.8.1/040). Here it was shown that N-acetyl glyphosate was marginally metabolised to glyphosate and N-acetyl AMPA, as only very small quantities (close to LOD) were detected in urine and plasma samples at day 82/83.
The analytical results from the 90-day study (CA 5.8.1/040) of urine and plasma samples from rats confirm that N-acetyl glyphosate was marginally metabolised to glyphosate and N-acetyl AMPA, as only very small quantities (close to LOD) were detected in urine and plasma samples at day 82/83.

The oral LD_{50} for N-acetyl glyphosate was determined to be > 5000 mg/kg bw (limit test), based on the results of an acute oral toxicity study in female rats. Mortality occurred in 20 % of the males and 40 % of females. Further, liquid/soft faeces and general clinical signs were observed in all surviving animals ([redacted] 2004, CA 5.8.1/039).
In a 90-day feeding study in rats, no adverse effects were noted on in-life parameters, neurobehavioral evaluation and clinical and anatomic pathology at any dose tested. Therefore, a NOAEL of 1157 and 1461 mg/kg bw/day was derived for males and females, respectively ([redacted], 2007, CA 5.8.1/040).

N-acetyl glyphosate was tested negative for mutagenicity in bacteria (Ames test) and mammalian cells (HPRT test) ([redacted], 2004, CA 5.8.1/041; [redacted] 2006, CA 5.8.1/043). Furthermore, no clastogenic activity was observed in an *in vitro* chromosomal aberration test in CHO cells and in an *in vivo* micronucleus test in mice ([redacted], 2004, CA 5.8.1/042; [redacted], 2006, CA 5.8.1/044).

2. Full summary

Executive summary

The pharmacokinetics, absorption, elimination, and metabolism were studied in male rats following a single oral administration of [^{14}C]-N-acetyl-glyphosate at a nominal dose of 15 mg free acid equivalent/kg bw. Blood was collected from four rats per time point up to 72 hours post-dose. Excreta were collected from five animals at specified intervals through 7 days post-dose. Plasma, urine, and faeces were analysed for unchanged parent compound and metabolites.

The mean total recovery of radioactivity was 95.5 %, with 66.1 % in urine, 26.4 % in faeces, 2.79 % in cage wash and wipe, and 0.23 % in residual carcass. More than 90 % of the total radioactivity was excreted within 48 hours. The mean maximum concentrations (Cmax) in blood and plasma were 2.93 and 5.31 µg equivalents/g 1 and 2 hours after application, respectively. Radioactivity was eliminated from blood and plasma with half-life values of 20.1 and 15.6 hours, respectively. Comparison of blood and plasma values for area under the curve (AUC) indicated that [^{14}C]-N-acetyl-glyphosate distributed preferentially into plasma.

Unchanged [^{14}C]-N-acetyl-glyphosate recovered in urine and faeces represented over 99 % of the administered radioactivity. A metabolite, glyphosate, was detected in faeces and represented less than 1 % of the total radioactivity. Plasma radioactivity consisted entirely of unchanged [^{14}C]-N-acetyl-glyphosate.

I. MATERIALS AND METHODS

A. MATERIALS

1. Non-labelled test material: N-acetyl-glyphosate

Identification: N-acetyl-glyphosate, sodium salt

Description: Not reported

Lot #: 123K5012 (PTRL West Log No. 1247W-001)

Purity: 84.3 % sodium salt (67.4 % based on free acid)

Stability of test compound: Responsibility of sponsor

2. Radiolabelled test material: [^{14}C]-N-acetyl-glyphosate

Identification: N-acetylglyphosate-phosphonomethyl-^{14}C

Position of radiolabel:

Lot #: 123K9416

Radiochemical purity: 99.181 % (confirmed by HPLC prior to dose preparation)

Specific activity: 8.0 mCi/mmol

Stability of test compound:	Stability was confirmed by pre- and post-dose HPLC analysis of radiochemical purity values
3. Analytical standard:	
Identification:	Glyphosate-phosphonomethyl - ^{14}C sodium salt
Lot No.	012K9430/31
Specific activity:	2.2 mCi/mmol
Radiochemical purity:	99.237 %
4. Vehicle:	Sterile water for injection
5. Test animals:	
Species:	Rat
Strain:	Sprague-Dawley (Crl:CD(SD)IGS BR)
Source:	[redacted]
Age:	10 weeks at dosing
Sex:	Males
Weight at dosing:	266 to 292 g at dosing
Acclimation period:	At least 4 days; all animals appeared clinically healthy throughout acclimation
In-life dates:	09 to 16 Mar 2004
Diet/Food:	Certified Rodent Diet #8728CM (Harlan Teklad, Inc.), *ad libitum*
Water:	Water, *ad libitum*
Housing:	During acclimatisation: Individual, suspended, stainless steel, wire mesh cages. During test period: Animals designated for collection of excreta were housed in individual Nalgene cages designed for the separation and collection of urine and faeces; Animals designated for pharmacokinetic analyses were housed in individual, suspended, stainless steel wire-mesh cages.
Environmental conditions:	Temperature: 22 ± 4 °C Humidity: 50 ± 20 % Air changes: not stated 12-hour light/dark cycle

B. STUDY DESIGN

Animal assignment and treatment

Administration

Group	Number of male rats	Route of dosing	Frequency of dosing	Dose level (mg/kg bw)	Dose Volume (mL/kg bw)	Radioactive dose (µCi/kg)	Sampling
1	5	Oral gavage	Single	15	5	100	Faeces, urine, cage wash, carcass
2	40*	Oral	Single	15	5	100	Blood

		gavage					

*4 animals per blood sampling time point

Animals were allocated to the different dose groups randomized based on body weight. Animals were fasted overnight through approximately 4 hours after application of 15 mg [^{14}C]-N -acetyl-glyphosate/kg bw.

Observation of animals

Cage-side observations

Animals were observed for mortality and signs of pain and distress twice daily. Cage side observations for general health and appearance were done once daily.

Body Weights

Animals were weighed at randomization and on the day of dose administration.

Animal assignment and treatment: Excretion/mass balance study (Group 1)

Each of five male rats received a single gavage administration of 15 mg [^{14}C]-N-acetyl-glyphosate/kg bw. Urine and faeces were collected at 0 - 6, 6 - 12, and 12 - 24 hour intervals and at 24-hour intervals through 168 hours. The weight of each sample was recorded. After the last excreta collections, cages were washed and wiped with a solution of methanol: 1 % trisodium phosphate (TSP) in water (50:50, v:v) and gauze pads. The cage wash samples and gauze were collected into separate plastic containers and the weight of each cage wash sample was recorded. Animals were sacrificed with an overdose of halothane anaesthesia and the residual carcass from each animal was retained.

Animal assignment and treatment: Pharmacokinetic study (Group 2)

Each male rat received a single gavage administration of 15 mg [^{14}C]-N-acetyl-glyphosate/kg bw. Four animals per time point were sacrificed via exsanguination (cardiac puncture) under halothane anaesthesia. Samples were collected pre-dose, and at 0.5, 1, 2, 4, 8, 12, 24, 48, and 72 hours post-dose. At sacrifice blood was collected via syringe and needle into tubes containing K_3EDTA anticoagulant from each animal. Blood was aliquoted for radio-analysis and centrifuged to obtain plasma.

Sample Preparation and radioanalysis

All sample combustions were done in a Model 307 Sample Oxidizer (Packard Instrument Company) and the resulting $^{14}CO_2$ was trapped in a mixture of Perma Fluor and Carbo-Sorb. Ultima Gold XR scintillation cocktail was used for samples analysed directly. All samples were analysed for radioactivity in liquid scintillation counters (Packard Instrument Company) for at least 5 minutes or 100,000 counts. Each sample was homogenized before radioanalysis (unless the entire sample was used for analysis). All samples were analysed in duplicate if sample size allowed. If results from sample duplicates (calculated as ^{14}C dpm/g sample) differed by more than 10 % from the mean value, the sample was re-homogenized and re-analysed (if the sample size permitted). This specification was met for all sample aliquots that had radioactivity greater than 100 dpm. Scintillation counting data (cpm) were automatically corrected for counting efficiency using the external standardization technique and an instrument-stored quench curve generated from a series of sealed quenched standards.

Blood and Plasma

Duplicate weighed aliquots of blood and plasma were analysed by LSC.

Urine and Cage Wash

Duplicate weighed aliquots of urine were analysed directly by LSC. If no urine sample was visible, a sufficient amount of water was added to thoroughly rinse the container, the sample was mixed by shaking, and duplicate aliquots were taken and analysed by LSC.

Faeces

A sufficient amount of methanol:water (50:50, v:v) was added to facilitate homogenization. Duplicate weighed aliquots were combusted and analysed by LSC.

Cage Wipe
A sufficient amount of methanol:water (50:50, v:v) was added to cover each sample. Samples were allowed to extract, mixed by gentle shaking, and duplicate weighed aliquots were analysed by LSC.

Carcass (residual)
Each sample was cut into pieces, which were frozen in liquid nitrogen and homogenized in a Wiley Mill that had been precooled with dry ice. Additional dry ice was ground to clear any remaining sample from the mill. After the dry ice had sublimed, the homogenate was digested in 1N sodium hydroxide. Duplicate weighed aliquots were taken and hydrogen peroxide was added in a dropwise fashion. After any foaming had dissipated, Ultima Gold XR scintillation cocktail was added, the aliquots were allowed to sit overnight and analysed by LSC.

Characterisation of Metabolites
Group 1 urine samples collected at 0 - 6, 6 - 12, 12 - 24, 24 - 48, and 48 - 72 hours post-dose were pooled across animals by time point. (Urine collected from Animal No. C16498 was excluded from the pool due to suspected cross-contamination of radioactivity between urine and faeces for this animal). Each pool was analysed by LSC. The pools were microfuged, and the supernatants were analysed by LSC and HPLC to determine the metabolic profile. The HPLC eluents for each pooled sample were also analysed by LSC.

Group 1 faeces samples collected from 6 - 12, 12 - 24, and 24 - 48 hours post-dose were pooled across animals by time point. (Faeces collected from Animal No. C16498 were not included in the pools; however, samples collected from this animal at 12 - 24 and 24 - 48 hours post-dose were analysed separately.) In general, aliquots from each pool or sample were oxidized and analysed by LSC. Approximately 1 to 5 g of each faeces pool or sample was extracted twice with approximately 10 mL of methanol. The samples were sonicated, shaken, and centrifuged. The supernatants were combined and analysed by LSC. The extraction solvent was evaporated under nitrogen. The remaining solids were then extracted twice with approximately 10 mL of mobile phase A (50 mM potassium phosphate, monobasic, pH 2:methanol 96:4, v:v). Samples were sonicated, vortex mixed, and centrifuged. The resulting mobile phase A supernatants were combined and analysed by LSC and HPLC. For two samples, the 6 to 12-hour pool and the 24-hour single sample, the methanol residues and the mobile phase A extracts were combined and the solvent was evaporated under nitrogen. The samples were reconstituted in mobile phase A:methanol (9:1, v:v), and microfuged. The resulting supernatants were analysed by HPLC to determine the metabolite profile. The HPLC column eluents for each pooled sample were also analysed by LSC. Following extraction and centrifugation, remaining solids were allowed to air dry, weighed, combusted, and analysed by LSC to determine the total extraction recovery.

Group 2 plasma samples collected at 0.5, 1, 2, 4, 8, 12, and 24 hours post-dose were pooled across animals by time point and the radioactivity in each pool was analysed by LSC. Approximately 3 to 6 mL of each plasma pool was extracted twice with approximately 3 times the volume of methanol. Samples were vortex mixed, sonicated, and centrifuged. The extracts were combined, analysed by LSC, and evaporated to near dryness. Plasma supernatants from the 8-, 12-, and 24-hour pools were further cleaned (using C18 solid phase extraction cartridge and eluting with water and methanol) then again reduced to dryness. Each sample was reconstituted in an appropriate volume of mobile phase A (50 mM potassium phosphate, monobasic, pH 2:methanol 96:4, v:v) and methanol (6:4 v:v). The samples were microfuged and each supernatant was analysed by HPLC to determine the metabolite profile. The post-extraction residues were dried, weighed, combusted, and analysed by LSC to determine the total extraction recovery.

Dose Preparation, Verification and Stability
The oral dose of [^{14}C]-N -acetyl-glyphosate was formulated as a solution in sterile water for injection at a nominal concentration of 3 mg/mL. The day before dose administration, 1.80 mL (containing 47.5 mg free acid) of [^{14}C]-N-acetyl-glyphosate and 331.8 mg N-acetyl-glyphosate salt were transferred into a serum

vial and combined with 88.2 mL of the dose vehicle. Duplicate weighed aliquots were taken from the dose formulation prior to and following dose administration, and were analysed by liquid scintillation counting (LSC) to determine the concentration of radioactivity and homogeneity. Stability was demonstrated by analysing pre-dose and post-dose aliquots by HPLC.

LC/MS and LC/MS/MS Analyses
Selected urine samples, and extracts of faeces and plasma were analysed using liquid chromatography mass spectrometry (LC/MS) ionised via negative electro spray ionisation. Based on the fulls can LC/MS data, a number of LC/MS/MS analyses were performed for structural elucidation. The LC/MS /MS analyses used the same instrumentation and conditions as for the negative ion full-scan LC/MS with minor modifications.

Data Analyses
Statistical analyses were limited to simple expressions of variation, such as mean and standard deviation. Dose tables were compiled with mean and standard deviation values calculated using Excel, Version 8.0e (Microsoft Corporation). Data tables were generated by Debra, Version 5.2a (LabLogic Systems Ltd., Sheffield, UK). Debra is an automated and validated data capture and management system for data collection in absorption, distribution, and excretion studies using radiolabeled test article. Debra captures data from balances and scintillation counters. The maximum concentration (Cmax) in blood and plasma and the time to reach maximum concentration (Tmax) were obtained by visual inspection of the raw data. Pharmacokinetic parameters calculated included half-life (t1/2), area under the concentration -time curve from time 0 to the last measurable time point (AUC_{0-t}), and area under the concentration-time curve from 0 to infinity ($AUC_{0-\infty}$). Pharmacokinetic parameters were calculated by using WinNonlin Professional Edition (Pharsight Corporation, Mountain View, CA).

Data evaluation
If results of sample analysis are below twice background, Debra reports the result as less than the limit of quantitation (BLQ). Values of BLQ are included as 0 in calculations of mean and variance. The concentration associated with the limit of quantitation is calculated as follows:
Limit of Quantitation (µg equivalents/g) = 2× Background (dpm)+Aliquot weight (g) f /Dose specific activity (dpm/µg)

The percent of administered dose associated with the limit of quantitation is calculated as follows:
Limit of quantitation (% of dose) = Limit of Quantitation (µg equivalents/g) × Sample weight (g) × 100/ µg administered

II. RESULTS AND DISCUSSION

A. TEST ARTICLE AND DOSE FORMULATION ANALYSIS

Radiochemcial purity and Stability
The HPLC analyses showed the radiochemical purity of [^{14}C]-N-acetyl-glyphosate to be 99.8 % prior to dosing. The mean radiochemical purity values obtained from HPLC analysis of pre-dose and post-dose aliquots from the dose solution were 99.9 % and 99.2 %, respectively, confirming stability of the test article under the conditions of the study. Representative stability chromatograms were presented.

Concentration and Homogeneity
The LSC analysis results indicated the dose solution was homogenous during the dosing period.

Specific Activity
The specific activity of the [^{14}C]-N-acetyl-glyphosate as provided by the sponsor was 37.9 µCi/mg. The mean specific activity of [^{14}C]-N-acetyl-glyphosate in the dose solution was determined to be 7.05 µCi/mg.

B. DOSE ADMINISTRATION

The volume of radiolabelled dose formulation to be administered to each animal by oral gavage was calculated based on the body weight taken on the day of dose administration. The actual amount administered was determined by weighing the dose syringe before and after dose administration. All animals were fasted overnight through approximately 4 hours post-dose.

Table 5.8.1-86: Mean body weights and radioactivity doses administered to male rats dosed orally with [^{14}C]-N-acetyl-glyphosate at a target dose of 15 mg/kg

Group	Number of male rats		Body weight (g)	Dose weight (g)	Actual dose administered				
					(dpm)	(mg/animal)	(mg/kg)	(µCi/animal)	(µCi/kg)
1	5	Mean	280	1.39	66457821	4.25	15.1	30.0	107
		SD	8	0.05	2375031	0.15	0.2	1.1	2
2	40	Mean	277	1.38	66246716	4.24	15.3	29.8	108
		SD	8	0.04	2114489	0.14	0.2	1.0	1

SD: Standard deviation. Dose concentration was 4.79 x 10^7 dmp/g. Dose specific activity was 7.05 µCi/mg.

C. CAGE-SIDE OBSERVATIONS

All animals appeared healthy and exhibited no overt signs of toxicity throughout the study.

D. EXCRETION AND MASS BALANCE

The mean total recovery of radioactivity from the five animals in Group 1 was 98.0 % with 57.2 % in urine, 37.6 % in faeces, 2.91 % in cage wash and wipe, and 0.26 % in residual carcass. More than 90 % of the total radioactivity was eliminated within 48 hours, with renal excretion being the primary elimination route. For animal No. C16498, 82.4 % of the administered radioactivity was detected in faeces, indicating probable urine contamination of the faeces. Excluding this animal, mean total recovery was 95.5 %, with 66.1 % in urine, 26.4 % in faeces, 0.23 % in carcass, and 2.79 % in cage wash/wipe.

Table 5.8.1-87: Percent of radioactive dose in urine, faeces, cage wash, cage wipe and carcass at specified intervals after a single oral administration of [^{14}C]-N-acetyl-glyphosate to male rats (n=5) at 15 mg/kg bw

E.PHARMACOKINETICS

Following a single oral administration, the mean maximum concentrations (C_{max}) in blood and plasma were 2.93 and 5.31 µg equivalents/g after 1 and 2 hours, respectively. The values for half-life ($t_{1/2}$), and area under the curve (AUC_{0-t}, and $AUC_{0-\infty}$) were 20.1 hours, 12.0 µg equivalents-hour/g, and 12.1 µg equivalents- hour/g in blood and 15.6 hours, 20.7 µg equivalents-hour/g and 20.8 µg equivalents-hour/g in plasma.

Table 5.8.1-88: Concentrations of radioactivity in blood and plasma at specified times after a single oral administration of [^{14}C]N-acetyl-glyphosate to male rats at 15 mg/kg bw

F. METABOLITE CHARACTERISATION

Nearly 100 % of the radioactivity was recovered in pooled urine after micro-centrifugation for HPLC analysis. Total extraction recoveries for pooled faeces ranged from 93.2 to 106 %, with 92.9 to 101 % extracted and 0.15 to 5.75 % remaining in the post extraction solid. The total extraction recoveries for pooled plasma collected from 0.5 to 8 hours post-dose ranged from 97.1 to 105 %, with 88.0 to 103 % extracted and 1.35 to 9.05 % remaining in the post extraction solid. Due to low levels of radioactivity in the samples collected at 12 and 24 after dosing, recoveries were low in these samples. Extracted radioactivity from selected samples was analysed by using HPLC with radioactivity flow detection and LC/MS/MS.
One radiolabelled component was detected by HPLC analysis of urine and extracts of faeces and plasma. This component had retention times similar to the [^{14}C]-N-acetyl-glyphosate reference standard when the samples and the standard were co-injected. LC/MS/MS analysis of this component in urine, plasma, and faeces provided molecular ion and production spectra that were virtually identical to that of the [^{14}C]-N-acetyl-glyphosate reference standard.

Urine
The HPLC profile in urine showed only unchanged [^{14}C]-N-acetyl-glyphosate. A total of 65.2 % of the administered [^{14}C]-N-acetyl-glyphosate was excreted in urine.

Faeces
The HPLC profile in faeces showed mostly unchanged [^{14}C]-N-acetyl-glyphosate, with trace amounts of a metabolite. This metabolite was identified as glyphosate by co-chromatography of a faeces extract with the [^{14}C]-glyphosate reference standard; the metabolite was not confirmed by LC/MS analysis, due to the low levels of radioactivity in faeces samples.

Plasma
The HPLC profile for plasma showed only unchanged [^{14}C]-N-acetyl-glyphosate in samples collected from 0.5 to 12 hours post-dose.

Table 5.8.1-90: Detected metabolites in pooled samples following a single oral administration of [^{14}C]-N-acetyl-glyphosate at 15 mg/kg bw to male rats (n=5)

Pooled sample type	Proposed identification	Retention time (minutes)	Percent of Sample Radioactivity				
			0 - 6h	6 - 12h	12 - 24h	24 - 48h	48 - 72h

III. CONCLUSIONS

Following a single oral administration of [^{14}C]-N-acetyl-glyphosate to male rats, approximately 66 % of the total radioactivity was excreted in urine and approximately 26 % in faeces. Over 90 % of the radioactivity was excreted within 48 hours post-dose. Minimal metabolism occurred, with unchanged [^{14}C]-N-acetyl-glyphosate representing more than 99 % of the total administered radioactivity detected in urine and faeces. Trace amounts of [^{14}C]-glyphosate, representing less than 1 % of the total radioactivity, were detected in faeces. [^{14}C]-N-acetyl-glyphosate was the only circulating radioactive component in plasma, and was eliminated from plasma with a half-life of 15.6 hours.

3. Assessment and conclusion

Assessment and conclusion by applicant:

A single oral dose of [^{14}C]-N-acetyl-glyphosate at 15 mg free acid equivalent/kg body weight was administered to five male Sprague-Dawley rats. Urine and faeces were collected at different time points. Upon sacrifice the cage was and carcasses were analysed for radioactivity. The mean total recovery of radioactivity after a collection period of 7 days was 95.5 % with 66.1 % in urine, 26.4 % in faeces, 2.79 % in cage wash and wipe, and 0.23 % in residual carcass.

Pharmacokinetics
Blood was collected over a sufficient time period as only trace amounts were detectable at 72 hours post-dose. [^{14}C]-N-acetyl-glyphosate was the only circulating radioactive component in plasma, and was eliminated from plasma with a half-life of 15.6 hours. The mean maximum concentrations (Cmax) in blood and plasma were 2.93 and 5.31 µg equivalents/g at 1 and 2 hours post-dose, respectively. Radioactivity was eliminated from blood and plasma with half-life values of 20.1 and 15.6 hours, respectively. Comparison of blood and plasma values for area under the curve (AUC) indicated that [^{14}C]-N-acetyl-glyphosate distributed preferentially into plasma.
The limit of quantitation was not explicitly stated in the report, but was <0.01 µg Equivalents [^{14}C]-N-acetyI-glyphosate/g for blood and plasma.

Absorption
N-acetyl-glyphosate is quickly absorbed after oral application as indicated by the urinary excretion. 47.7 % of the applied radioactivity was excreted within 6 h after application. 63.4 % of the applied radioactivity was excreted within 24 h (excluding cage wash). This supported by Tmax values being 1 and 2 hours in blood and plasma, respectively.

Elimination
Approximately 66 % of the total radioactivity was excreted in urine and approximately 26 % in faeces. Over 90 % of the radioactivity was eliminated within 48 hours post-dose.

Metabolism
No metabolites were detected in plasma and urine. Plasma and urine radioactivity consisted entirely of unchanged [^{14}C]-N-acetyl-glyphosate. Unchanged [^{14}C]-N-acetyl-glyphosate recovered in urine and faeces represented over 99 % of the administered radioactivity. A metabolite found at less than 0.25 % of the administered radioactivity in faeces was glyphosate, which was formed by N-deacetylation.

Conclusion:
The study mainly focused on metabolism, elimination and pharmacokinetics of N-acetyl-glyphosate after single oral administration to male rats. Methods and results are acceptable and can be used as reliable supplementary data.

Assessment and conclusion by RMS:

Acute oral toxicity

CA 5.8.1/039

2. Full summary

Executive summary

The toxicity of the test article, N-acetyl-glyphosate (as the free acid), was evaluated following a single oral dose to the rat. The test article was suspended in cell culture grade water and administered by oral gavage at a dose level of 5000 mg/kg bw to five rats/sex. The rats were observed for mortality, body weight effects and clinical signs for 15 days after dosing. All animals were subjected to an abbreviated gross necropsy examination of the external features of the carcass, external body orifices, the abdominal, thoracic and cranial cavities and organs/tissues.

Mortality was observed in one female at the 4-hour post-dose observation interval and in one male and one female during the a.m. check on Day 2. All the remaining males and females survived until the scheduled sacrifice. Clinical observations observed in the males included hypoactivity, irregular respiration, liquid or soft feces, light-brown perineal staining, brown nasal crust and/or squinted eyes. Clinical observations observed in the females included slight hypoactivity, irregular respiration, liquid or soft feces and/or light-brown perineal staining. All clinical signs of toxicity were resolved in all surviving animals by Day 3.

All surviving animals gained weight from initiation of dosing to study termination. At necropsy, findings were noted in the one male and two females that were found dead prior to the terminal sacrifice, however no abnormal findings were noted in the remaining animals at necropsy. Findings in one male and one female involved the lungs (mottled or discolored bright-red), liver (discolored black), stomach (soft and/or with yellow fluid), abdominal cavity (fluid/clear fluid), and duodenum, jejunum and ileum (fluid). Finding in the second male involved the stomach (gel-like clear liquid and red walls), abdominal cavity (reddish-liquid), duodenum, jejunum and ileum (fluid).

Under the conditions of this study, the oral LD_{50} of the test article is greater than 5000 mg/kg bw. The mortality rate was 20 % in the males and 40 % in the females dosed at 5000 mg/kg.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:

Identification:	N-acetyl-glyphosate, sodium salt
Description:	White powder
Lot/Batch #:	123K5012 (1247W-001)
Purity:	84.3 % sodium salt
Stability of test compound:	The test substance appeared to be stable under the conditions of the study (sponsor's responsibility). Expiry date: 2006-02-10.

2. Vehicle and/ or positive control:	Cell culture grade water (Bio Whittaker/Cambrex; Lot No. 01102570; Expiration Date: 2005-08-04) / none

3. Test animals:

Species:	Rat
Strain:	Crl:CD®(SD)IGS BR
Source:	[redacted]
Age:	8 – 12 weeks
Sex:	Male and female
Weight at dosing:	♂ 223 – 247 g; ♀ 231 – 242 g
Acclimation period:	5 days
Diet/Food:	PMI® Nutrition International, LLC Certified Rodent LabDiet® 5002, *ad libitum*
Water:	Water, *ad libitum*
Housing:	Individually in sanitary, stainless-steel, screen-bottomed, hanging, wire cages
Environmental conditions:	Temperature: 18 – 26 °C Humidity: 50 ± 20 % Air changes: ≥10 air changes / hour 12 hours light / dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 2004-04-01 to 2004-04-16

Animal assignment and treatment:
A limit test using five animals/sex at a dose level of 5000 mg/kg bw was conducted. The animals were fasted overnight (17 to 20 hours before test material administration) and for approximately 4 hours after dosing. Dose calculations were adjusted by a factor of 67.4 % to obtain a dose of the free acid. On the day of dosing the test material was suspended in the vehicle, forming an opaque, viscous, white, homogeneous suspension. Individual doses were calculated based on each animal's fasted body weight taken just before test material administration and a dose volume of 10 mL/kg bw.
The test article was administered orally via a gavage needle attached to a disposable syringe. An assigned syringe and oral gavage needle was used for each dosing group. Prior to dose administration to each animal, the gavage needle was wiped with paper towels.

Table 5.8.1-91: Acute Oral Toxicity Study in Rats with N-Acetyl-Glyphosate, Sodium Salt (Acute Toxic Class

Method) ([redacted], 2004): Study design and mortality

Test group	Dose level [mg/kg bw]	Mortality / number of animals	
		Males	Females
N-acetyl-glyphosate, sodium salt	5000	1/5	2/5

Analysis of the test substance
The analysis of the test substance was in the responsibility of the sponsor.

Mortality
The animals were observed for general health and mortality at least once daily during acclimation and twice daily (at least 4 hours apart) for the duration of the study.

Clinical observations
Observations were performed for clinical signs of toxicity pre-dose on the day of dosing (Day 1), continuously for the first hour post-dose and at approximately 4 and 8 hours post-dose. Daily observations were performed thereafter until the day prior to sacrifice.

Body weight
The animals were weighed pre-dose on the day of dosing (Day 1; fasted), on Days 8 and 15, and at termination (Day 16; fasted).

Sacrifice and pathology
After 15 days of observation, all surviving animals were food fasted overnight, weighed (Day 16) and anesthetised with an appropriate barbiturate.

Necropsy
All animals were subjected to an abbreviated gross necropsy examination of the external features of the carcass, external body orifices, the abdominal / thoracic / cranial cavities and organs / tissues. Any abnormalities were recorded. After necropsy, the animals were discarded; no tissues were saved.

Statistics
Other than the calculation of the LD_{50} and the descriptive statistics of the body weights (when applicable) no statistical analyses were required.

II. RESULTS AND DISCUSSION

A. MORTALITY
Mortality was observed in one female at the 4 hour post-dose observation interval and in one male and one female during the a.m. check on Day 2. All the remaining males and females survived until the scheduled sacrifice. Please refer to the table above.

B. CLINICAL OBSERVATIONS
Clinical observations observed in the males included slight and distinct hypoactivity, irregular respiration, liquid or soft faeces, brown nasal crust, light-brown perineal staining and/or squinted eyes. Clinical observations observed in the females included slight hypoactivity, irregular respiration, liquid or soft faeces and/or light-brown perineal staining. All clinical signs of toxicity were resolved in all surviving animals by Day 3.

C. BODY WEIGHT
All surviving animals gained weight from initiation of dosing to study termination.

D. NECROPSY

Findings were noted in the one male and two females that were found dead prior to the terminal sacrifice, however no abnormal findings were noted in the remaining animals at necropsy. Findings in one male and one female involved the lungs (mottled or discoloured bright-red), liver (discoloured black), stomach (soft and/or with yellow fluid), abdominal cavity (fluid/clear fluid), and duodenum, jejunum and ileum (fluid). Finding in the second male involved the stomach (gel-like clear liquid and red walls), abdominal cavity (reddish-liquid), and duodenum, jejunum and ileum (fluid).

Table 5.8.1-92: Acute Oral Toxicity Study in Rats with N-Acetyl-Glyphosate, Sodium Salt (Acute Toxic Class Method) ([redacted], 2004): Necropsy findings

Animal number	Sex	Dose level [mg/kg bw]	Day of death	Necropsy Observation
5045	Male	5000	Terminal	No abnormal findings
5046	Male		Terminal	No abnormal findings
5047	Male		Terminal	No abnormal findings
5048	Male		Day 2	Lungs – mottled Liver – discoloured black Stomach – soft Abdominal cavity – clear fluid Duodenum, jejunum, ileum – fluid
5049	Male		Terminal	No abnormal findings
5050	Female		Terminal	No abnormal findings
5051	Female		Day 2	Lungs – discoloured bright-red Liver – discoloured black Stomach – soft with yellow fluid Abdominal cavity – fluid Duodenum, jejunum, ileum – fluid
5052	Female		Day 1	
5053	Female		Terminal	No abnormal findings
5054	Female		Terminal	No abnormal findings

III. CONCLUSIONS

Under the conditions of this study, the oral LD_{50} of the test article is greater than 5000 mg/kg bw. The mortality rate was 20 % in the males and 40 % in the females dosed at 5000 mg/kg bw. The test material, N-acetyl-glyphosate, sodium salt was toxic when administered once by oral gavage at a dose level of 5000 mg/kg bw (as the free acid) in male and female rats under the conditions of this assay.

3. Assessment and conclusion

Assessment and conclusion by applicant:
This study is considered to be valid as it was conducted under GLP and no deviations from the recent guideline could be identified.
Under the conditions of this study, the oral LD_{50} of N-acetyl-glyphosate, sodium salt is greater than 5000 mg/kg bw.

Assessment and conclusion by RMS:

Short-term toxicity

CA 5.8.1/040

Report author	[redacted] [redacted] supplement author)
Report year	2007
Report title	IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats
Report No	[redacted]-19008
Document No	NA
Guidelines followed in study	OPPTS 870.3100 (1998); OECD Guideline 408 (1998); Method B.26, Directive 2001/59/EC (2001); MAFF 2-1-9 Notification 12 Nousan 8147 and Notification 13 Seisan 1739 (2000 and 2001)
Deviations from current test guideline (OECD 408, 2018)	Clinical chemistry was performed without determining LDL, HDL, T3, T4 and TSH; organ weights were determined without prostate (+ seminal vesicles and coagulating glands), thyroid and pituitary gland; histopathology was performed without cervix, coagulating glands, gall bladder and male mammary glands.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

The objective of this study was to assess the potential sub-chronic toxicity of IN-MCX20 in rats. Five groups of young adult male and female Crl:CD(SD) rats (10/sex/group) were administered diets that contained 0, 180, 900, 4500 or 18000 ppm IN-MCX20 (equivalent to 0, 11.3, 55.7, 283 and 1157 mg/kg bw/day for males and 0, 13.9, 67.8, 360 and 1461 mg/kg bw/day for females) for approximately 90 days (95 days in males and 96 days in females). Samples of the diets were analysed to assess homogeneity, stability, and concentration of the test substance in the diet. Body weights, food consumption and detailed clinical observations were evaluated weekly. Ophthalmological and neurobehavioral (abbreviated functional observational battery, grip strength, motor activity) evaluations were performed on all rats prior to the start of dietary exposure and near the end of the exposure period. Clinical pathology endpoints (haematology, coagulation, clinical chemistry and urinalysis with metabolic analysis of IN-MCX20 (N-acetyl glyphosate) and its possible metabolites, IN-B2856 (glyphosate) and IN-EY252 (N-acetyl AMPA)) were evaluated at the end of the exposure period. After approximately 90 days of dietary exposure, the surviving rats were sacrificed and given a gross and microscopic pathological examination.

Analysis of the diets demonstrated that IN-MCX20 was present at the targeted concentrations and was stable under relevant storage conditions. The homogeneity of the test substance in the initial diet preparations, in particular at the 180 ppm concentration, indicated a coefficient of variance (CV) of >10 %. However, most individual diet samples were within the targeted concentration range, and analysis of subsequent diet preparations supported adequate homogeneity. Therefore, it was concluded that the rats were exposed to the targeted concentrations of test substance. The overall mean daily intake of IN-MCX20 in the 0, 180, 900, 4500 or 18000 ppm groups was 0, 11.3, 55.7, 283 and 1157 mg/kg bw/day, respectively, for male rats and 0, 13.9, 67.8, 360 and 1461 mg/kg bw/day, respectively, for female rats.

No adverse test substance-related effects on any body weight or nutritional parameters were observed. Statistically significantly lower overall mean body weight gain (86 % of control) was observed in 18000 ppm males but was not considered adverse as it was not associated with a statistically significant difference in mean final body weight or in overall mean food consumption or food efficiency.

No test substance-related deaths occurred and no clinical, ophthalmological or neurobehavioral observations were attributed to exposure to the test substance. There were no adverse effects on clinical pathology parameters, organ weights, gross pathology, or microscopic pathology in male or female rats.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Disodium N-acetyl-N-(phosphonomethyl)glycine
Identification:	IN-MCX20
Description:	White solid
Lot/Batch #:	27419
Purity:	63 %
Stability of test compound:	The test substance appeared to be stable under the conditions of the study and the study was completed prior to the expiration date on the Certificate of Analysis. No evidence of instability, such as a change in colour or physical state, was observed.
2. Vehicle and/ or positive control:	Diet / none
3. Test animals:	
Species:	Rat
Strain:	Crl:CD(SD)
Source:	[redacted]
Age:	7 weeks
Sex:	Male and female
Weight at dosing:	♂ 235.1 – 236.5 g; ♀ 173.8 – 175.9 g
Acclimation period:	6 days
Diet/Food:	PMI® Nutrition International, LLC Certified Rodent LabDiet® 5002, *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually in stainless steel, wire-mesh cages suspended above cage boards
Environmental conditions:	Temperature: 18 – 26 °C Humidity: 30 – 70 % Air changes: Not reported 12 hours light / dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 2007-05-18 to 2007-02-16

Animal assignment and treatment:
The test substance, IN-MCX20, was administered on a continuous basis in the basal diet for 95 or 96 days to 4 groups of (Crl:CD(SD)) rats. Dose levels were 180, 900, 4500 and 18000 ppm (equivalent to 0, 11.3, 55.7, 283 and 1157 mg/kg bw/day for males and 0, 13.9, 67.8, 360 and 1461 mg/kg bw/day for females). A concurrent control group received the basal diet on a comparable regimen. Each group consisted of 10 animals per sex.

Table 5.8.1-93: IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted] 2007): Study design

Test group	Dietary concentration [ppm]	Mean daily intake mg/kg bw/day	Number of animals	
			Males	Females
Control	0	♂: 0; ♀: 0	10	10
Low	180	♂: 11.3; ♀: 13.9	10	10

Intermediate low	900	♂: 55.7; ♀: 67.8	10	10
Intermediate high	4500	♂: 283; ♀: 360	10	10
High	18000	♂: 1157; ♀: 1461	10	10

Analysis of the test substance
IN-MCX20 was initially hand mixed with 500 grams of chow. Subsequently, this pre-mix was added to the diet and thoroughly mixed for a period of time that, by experience, was considered adequate to ensure homogeneous distribution in the diet. The manufacturer and production code of the feed was recorded in the study records. Diets were prepared weekly and refrigerated until used.
Duplicate samples (concentration and homogeneity verification) of all dietary concentrations were collected at the initial diet preparation and analysed to verify the concentration of IN-MCX20 in the diets. Duplicate samples were taken from the lowest and highest dietary concentration of the initial diet preparation and analysed to verify the stability of IN-MCX20 in the diets. The stability of IN-MCX20 in feed was demonstrated by comparing samples stored at room temperature or refrigerated with the mean measured values of the concentration (middle homogeneity) verification samples. Because of difficulties encountered with development of an analytical method, insufficient diet samples collected at study start were available to verify homogeneity in the diet. The analytical results of the middle homogeneity samples from this time point were used to support concentration at study start. Additional diet samples were collected from the top, middle, and bottom of the diet mixer of all dietary concentrations during the middle of the study and evaluated to confirm homogeneity of mixing, as well as to verify concentration at this time point. Toward the end of the study, additional samples were taken to verify concentration.

Mortality
Cage-site examinations to detect moribund or dead rats were conducted at least twice daily throughout the study.

Clinical observations
Cage-site examinations to detect abnormal behaviour and/or appearance among rats were conducted at least twice daily throughout the study. Abnormal behaviour/appearance was recorded by exception.
An additional cage-site evaluation was conducted daily, except on the days when detailed clinical observations were conducted, at approximately the same time (± 2 hours). Acute clinical signs of systemic toxicity were recorded.
At every weighing, each rat was individually handled and examined for abnormal behavior and appearance. Detailed clinical observations in a standardised arena were also evaluated on all rats. The detailed clinical observations included (but were not limited to) evaluation of fur, skin, eyes, mucous membranes, occurrence of secretions and excretions, autonomic nervous system activity (lacrimation, piloerection and unusual respiratory pattern), changes in gait, posture, response to handling, presence of clonic, tonic, stereotypical or bizarre behavior. Any abnormal clinical signs noted were recorded.

Body weight
All rats were weighed once per week.

Food consumption and test substance intake
The amount of food consumed by each rat over each weighing interval was determined throughout the study. From these determinations and body weight data, mean daily food consumption, mean food efficiency, and mean daily intake of IN-MCX20 were calculated.

Abbreviated Functional Observational Battery (FOB)
Sensory and motor function assessments were conducted by evaluating grip strength, responses to approach/touch, sharp auditory stimulus, and tail pinch, and pupillary constriction prior to administration and in week 13. Fore- and hind-limb grip strength was measured by a strain gauge device (Chatillon® Digital Force gauge). Responses to approach/touch, sharp auditory stimulus, and tail pinch were made while the animal was in a standard arena. Pupillary constriction was assessed after a beam of light was directed into each eye prior to removing the rats from the motor activity chambers because the darkened room in

which the apparatus was located facilitated observing the response.

Motor activity evaluation
Following the abbreviated functional observational battery, assessment of motor activity (MA) was conducted prior to treatment and in week 13. Rats were individually tested in 1 of 30 identical, automated activity monitors (Coulbourn® Infrared Motor Activity System). Group and sex were counterbalanced across the monitors and time of day to the fullest extent possible. The infrared monitoring device enables measurement of 2 dependent variables: duration of movement and number of movements. A continuous movement was counted as 1 movement regardless of duration. Each test session was 60 minutes in duration, and the results were expressed for the total session, as well as for 6 successive 10-minute blocks.
Presence of diarrhoea and polyuria on the cage boards below the motor activity monitor were also recorded following each motor activity session.

Ophthalmoscopic examination
Ophthalmology examinations were conducted by a veterinary ophthalmologist. Both eyes were examined by focal illumination and indirect ophthalmoscopy. The examinations were conducted under subdued lighting after mydriasis had been produced with a 1 % tropicamide solution. On test day -15, the initial examination was performed on all rats received for the study, prior to selection and grouping. All surviving rats were examined on test day 85 prior to the scheduled sacrifice.

Haematology, clinical chemistry and urinalysis
A clinical pathology evaluation was conducted on all animals on test days 95 – 96. The day before collection of samples for the clinical pathology evaluation, the animals were placed in metabolism cages. These animals were fasted after 3 p.m. for at least 15 hours and urine was collected from each animal. Blood samples for haematology and clinical chemistry measurements were collected from the orbital sinus of each animal while the animal was under carbon dioxide anaesthesia. Blood samples for coagulation parameters were collected at sacrifice from the abdominal vena cava of each animal while the animal was under carbon dioxide anaesthesia.
Additional blood collected from the vena cava was placed in a serum tube, processed to serum, and frozen at approximately -80 °C. Serum will be discarded without analysis because further tests were not required to support experimental findings. Bone marrow smears were prepared at sacrifice from all surviving animals. Bone marrow smears were stained with Wright-Giemsa stain, but analysis was not necessary to support experimental findings. All blood samples were evaluated for quality by visual examination. Results were maintained in the study records and reported only if the sample was analysed.

The following haematological parameters were evaluated: Red blood cell count, red cell distribution width, haemoglobin, absolute reticulocyte count, haematocrit, platelet count, mean corpuscular (cell) volume, white blood cell count, mean corpuscular (cell) haemoglobin, differential white blood cell count, mean corpuscular (cell) haemoglobin concentration, microscopic blood smear examination, prothrombin time and activated partial thromboplastin time.
The following clinical chemistry parameters were evaluated: Aspartate aminotransferase, alanine aminotransferase, sorbitol dehydrogenase, alkaline phosphatase, total bilirubin, urea nitrogen, creatinine, cholesterol, triglycerides, glucose, total protein, albumin, globulin, calcium, inorganic phosphorus, sodium, potassium and chloride.
The following urinalysis parameters were evaluated: Quality, colour, clarity, volume, osmolality, pH, glucose, ketone, bilirubin, blood, urobilinogen, protein and microscopic urine sediment examination.

Metabolite analysis
Additionally pooled urine samples for each treatment group were taken on Day 82 (males) and Day 83 (females) and individually plasma samples were taken on the same days to analyse N-MCX20 (N-acetyl glyphosate) and its possible metabolites, IN-B2856 (glyphosate) and IN-EY252 (N-acetyl AMPA).
The rat urine samples were prepared by adding 0.935 mL of 10 % formic acid to 0.05 mL of urine sample. The mixture was vortexed and 0.015 mL of $HClO_4$ was added. Finally, it was centrifuged after vortexing and the solution was transferred to a LC vial for LC/MS/MS analysis. The amount of 10 % formic acid

was reduced to 0.185 mL when analyte concentrations in the samples were very low (i.e., samples from the 180 and 900 ppm groups) and a more sensitive LC/MS/MS method was used to analyse these samples.
The rat plasma samples were prepared by adding 0.05 mL of trifluoroacetic acid to 0.05 mL of plasma sample. The mixture was vortexed well and 0.4 mL of 10 % formic acid was added. Finally, it was centrifuged after vortexing and the solution was transferred to a LC vial for LC/MS/MS analysis.
The individual stock solutions of IN-MCX20, IN-B2856 and IN-EY252 were prepared in NANOpure® water. The stock solutions were then used to prepare calibration standards in the control rat urine or plasma matrices. Each calibration standard contained all three analytes at the similar concentrations.

Sacrifice and pathology
After approximately 90 days on study (test day 95 for males and 96 for females), all male and female rats from each exposure group (0, 180, 900, 4500 and 18000 ppm) were sacrificed and necropsied for evaluation of sub-chronic toxicity. Rats sacrificed by design were fasted after 3 p.m. on the afternoon preceding the day of sacrifice. The order of sacrifice for scheduled deaths was stratified across dose groups within each sex. Rats were euthanised by carbon dioxide anaesthesia and exsanguination. Gross examinations were performed on all rats. Gross observations, final body weights and organ weights were recorded.

Organ weights
The following organs were weighed from all animals at the scheduled necropsy: Liver, kidneys, heart, spleen, thymus, adrenal glands, brain, testes, epididymides, ovaries (including oviducts), and uterus (including cervix). Group mean values and organ weight ratios (% body weight and % brain weight) were calculated.

Histopathology
The following organs were examined: Adrenals, aorta, bone with marrow (with femur and sternum), bone marrow smear, brain, epididymides, eyes, oesophagus, stomach, duodenum, jejunum, ileum, Peyer's Patches, caecum, colon, rectum, heart, kidneys, larynx, liver, lungs, lymph nodes (mandibular and mesenteric), nasal cavity, mammary gland (females only), ovaries, pancreas, peripheral nerve, pharynx, pituitary, prostate, salivary glands, seminal vesicles, skeletal muscle, skin, spinal cord, spleen, testes, thymus, thyroid/parathyroids, trachea, urinary bladder, uterus, vagina and all gross lesions and masses.

Statistics
Significance was judged at $p<0.05$. Separate analyses were performed on the data collected for each sex.

Table 5.8.1-94: IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted] 2007): Statistical analysis

Parameter	Preliminary Test	Method of Statistical Analysis	
		If preliminary test is not significant	If preliminary test is significant
Body weight Body weight gain Food consumption Food efficiency Clinical pathology Organ weight	Levene's test for homogeneity and Shapiro-Wilk test for normality	One-way analysis of variance followed by Dunnett's test	Kruskal-Wallis test followed by Dunn's test
Survival Incidence of FOB Descriptive parameters	None	Sequential application of Cochran-Armitage test for trend	
Motor activity Grip strength	Levene's test for homogeneity and Shapiro-Wilk test for normality	Repeated measures analysis of variance followed by Linear contrasts	Sequential application of the Jonckheere-Terpstra trend test

II. RESULTS AND DISCUSSION

A. TEST SUBSTANCE ANALYSIS

The results of diet analysis from samples submitted mid-study demonstrate that the test substance was homogeneously distributed (coefficients of variance [CV] = 4 – 10 %) and was at the targeted concentrations (± 13.7 % of nominal) in all diets. Analysis of diet samples from the end of the diet also demonstrated that all diets were at targeted concentrations (± 17.8 % of nominal). No test substance was detected in any control diet samples.

The results of diet analysis from samples submitted at study start demonstrate that the test substance was stable in the diet under relevant storage conditions (up to 21 days at room temperature or refrigerated). A few of the stability samples were not within the targeted concentration range, including 0-day room temperature 180 ppm sample (65.0 % of nominal) and 14-day room temperature 18000 ppm sample (140.6 % of nominal). All other stability samples were within 20.6 % of nominal. Except for the 180 ppm diet, the mean concentrations in fresh diets collected at study start were within 15.8 % of nominal.

The low value (65 % of nominal) measured in the 0-day room-temperature 180 ppm diet sample did not represent instability of the test substance. This is supported by the fact that this low value was measured in the freshly collected sample stored frozen until analysed. In addition, other 180 ppm samples collected from the same diet mixing and analysed for stability assessment were within an acceptable range, and there was no reduction in concentration over time for samples stored at either room temperature or refrigerated for either concentration.

Since the stability analysis did not demonstrate any breakdown of test substance in the diet matrix, it can be assumed that the concentration measured in all samples was comparable to the concentration at the time of mixing. Therefore, the concentration and homogeneity of test substance in the samples of diets collected at study start, at the time of mixing, can be estimated based on the mean and CV of all of the stability samples. Based on these stability sample data, the mean concentration of test substance in the two diets was estimated to be at the targeted levels (± 9 %) for both diets.

Although the initial homogeneity, based on these stability sample data, was outside the Haskell targeted range (CV <10 %), this was driven mainly by one outlier value in each diet. Excluding the one high value for the 18000 ppm diet, the CV for this diet was within the Haskell targeted range. These data, combined with the homogeneity data from the mid-study samples, support that the diets were at the targeted range and fairly homogeneously mixed, especially at the higher concentrations. The homogeneity data in the 180 ppm diet may represent true lower homogeneity at this concentration. However, most of the samples at this concentration at study start fell within the acceptable targeted concentration range (± 20 % of nominal). Since this concentration was below the NOAEL, the analytical results are not critical in evaluating the results of exposure to the test substance.

Thus, the animals were considered to have received the targeted concentration of test substance in the diets over the course of the study.

B. MORTALITY

No test substance-related deaths occurred. One male in the 4500 ppm group was found dead on test day 42. This death was attributed to trauma and not to exposure to the test substance. All other rats survived to scheduled sacrifice.

C. CLINICAL OBSERVATIONS

No clinical observations were attributed to test substance exposure. All observed signs were those typically seen in rats of this age and in this type of study.

D. BODY WEIGHT

No adverse effects on body weight or body weight gain were observed in male rats. Final (test day 91) mean body weight in the 18000 ppm group was 92 % of control (not statistically significant) and mean body weight in this group was not significantly different from control on any test day. Statistically significantly lower overall (test day 0 – 91) body weight gain was observed in male rats in the 18000 ppm group (86 % of control). However, while mean weekly body weight gain was lower than control over most

weekly intervals, the difference was only statistically significant over one weekly interval (test days 35 – 42), and body weight gain in this group exceeded that of control over two subsequent weekly intervals (not statistically significant). Therefore, this lower body weight gain was considered test substance-related but not adverse, as it didn't result in significantly lower mean body weight, and was not associated with a significant reduction in food consumption or food efficiency. No test substance-related effects on body weight or body weight gain were observed in any other male group. A statistically significant difference (reduction) in mean body weight gain was observed in the male 180 ppm group over test days 35 – 42. However, this difference was not considered test substance-related as there was no dose response.
No effects on body weight or body weight gain were observed in any female group. Final body weight and overall body weight gain in the female 18000 ppm group were 99 % and 97 % of control, respectively. Neither difference was statistically significant. No statistically significant difference in mean body weight or body weight gain was observed in any female dose group on any test day.
Lower body weight gain and/or body weight loss was observed in all male and female dose groups over the test day 77 – 84 interval. This lower weight gain is attributed to the stress of blood and urine collection on test days 82 (males) or 83 (females).

Table 5.8.1-95: IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2007): Selected body weight gain values

E. FOOD COMSUMPTION, FOOD EFFICIENCY AND DAILY INTAKE

No adverse effects on food consumption were observed in male or female rats. Overall food consumption in the 18000 ppm male and female groups was 93 % and 105 % of control, respectively. Neither difference was statistically significant. Statistically significantly lower mean food consumption, compared to control, was observed over one weekly interval each in all male dose groups except the 900 ppm group. Statistically significantly higher mean food consumption was observed in the 4500 ppm and 18000 ppm female groups over one or three weekly intervals. None of these differences was considered test substance related as overall mean food consumption was not significantly different from control.
No adverse effects on food efficiency were observed in male or female rats. Overall food efficiency in the 18000 ppm male and female groups was 92 % of control in both males and females. Neither difference was statistically significant. Mean weekly food efficiency was significantly lower than control in 18000 ppm males over test days 7 – 14 and in 180 ppm males over test days 35 – 42. These differences were not considered adverse as overall food efficiency was not significantly lower than control. No statistically significant differences in weekly food efficiency were observed in any female group during the study.
Mean daily intake of IN-MCX20 in males in the 0, 180, 900, 4500 and 18000 ppm groups was 0, 11.3, 55.7, 283 and 1157 mg/kg bw/day, respectively. Mean daily intake of IN-MCX20 in females in the 0, 180, 900, 4500 and 18000 ppm groups was 0, 13.9, 67.8, 360 and 1461 mg/kg bw/day, respectively.

F. OPHTHALMOLOGICAL EXAMINATIONS

No ophthalmological observations were attributed to test substance exposure. All observed signs were those typically seen in rats of this age and in this type of study.

G. NEUROBEHAVIORAL EVALUATIONS

Abbreviated Functional Observational Battery

There were no test substance-related or statistically significant effects for fore- or hind-limb grip strength and for any behavioural parameter in either males or females administered dietary concentrations of 180, 900, 4500 or 18000 ppm of the test substance.

Motor Activity

There were no test substance-related or statistically significant effects on duration of movement or number of movements in either males or females administered dietary concentrations of 180, 900, 4500 or 18000 ppm of the test substance.

H. HAEMATOLOGY, CLINICAL CHEMISTRY AND URINALIYIS

Haematology

There were no adverse changes in haematological parameters in male or female rats. The following statistically significant changes in mean haematological parameters were not adverse or not related to exposure to the test substance.

Mean monocyte count was mildly decreased at test day 95 in males fed 18000 ppm (mean was 61 % of the control group). Individual monocyte counts were within the overall range observed historically in similarly aged control rats, but several males fed 18000 ppm had values that were below the 95 % historical reference interval. This change was of uncertain relationship to treatment. Regardless, decreases in monocyte counts have no clinical significance; therefore, this change was considered to be non-adverse.

Minimally increased mean neutrophil count at test day 95 in males fed 4500 ppm was considered to be unrelated to treatment and non-adverse, because it was not dose-related.

Table 5.8.1-98: IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2007): Selected haematological parameters

Parameter	Dose group [ppm]									
	Males					Females				
	0	180	900	4500	18000	0	180	900	4500	18000
Monocytes [×10³/µL]	0.28 ± 0.11	↓0.25 ± 0.06	↓0.27 ± 0.11	↓0.27 ± 0.11	**↓0.17* ± 0.07**	0.22 ± 0.10	↓0.20 ± 0.09	↓0.21 ± 0.06	0.22 ± 0.11	↓0.23 ± 0.13
Neutrophils [×10³/µL]	1.36 ± 0.41	↑1.72 ± 0.37	↑1.68 ± 0.40	**↑2.04* ± 0.88**	↑1.41 ± 0.51	1.42 ± 1.04	↓1.15 ± 0.58	↓1.10 ± 0.31	↓1.31 ± 0.54	↓1.15 ± 0.47

*: Statistically significant from control (p≤0.05; Dunnett/Tamhane-Dunnett test)

There were no treatment-related or statistically significant changes in coagulation parameters in male or female rats.

Clinical Chemistry

There were no adverse or treatment-related changes in clinical chemistry parameters in male or female rats. Decreased glucose at test day 95 in males fed 900 ppm was considered to be unrelated to treatment and non-adverse because it was not dose-related.

Table 5.8.1-99: IN-MCX20: Subchronic Toxicity 90-Day Feeding Study in Rats ([redacted], 2007): Selected clinical chemistry parameters

Parameter	Dose group [ppm]									
	Males					Females				
	0	180	900	4500	18000	0	180	900	4500	18000

[$]: Statistically significant from control (p≤0.05; Dunn's test)

Urinalysis

There were no statistically significant or treatment-related changes in urinalysis parameters in male or female rats.

Urinalysis – Metabolic analysis

Rat Urine Sample Results

The urinary concentrations of IN-MCX20 increased with the increasing dietary levels of this test substance. Concentrations of IN-B2856 and IN-EY252 were detected above the limit of detection at higher dietary levels (900 to 18000 ppm) but at or below the limit of detection in urine samples from the 180 ppm dietary group. Further, the concentrations of these metabolites were much higher in urine samples from male rats than from corresponding female rats at 4500 and 18000 ppm. Neither IN-MCX20 nor either metabolite was detected in urine from control rats.

Rat Plasma Sample Results

The concentrations of IN-MCX20 also increased with the increasing dietary levels of this test substance. Concentrations of IN-MCX20 were <1.0 µg/mL for males and females in the 180 ppm dietary group. The concentrations increased from ~2 µg/mL up to ~14 µg/mL for the other dietary groups. In contrast to urine samples, little to none of IN-B2856 or IN-EY252 was detected for all dietary levels. Neither IN-MCX20 nor either metabolite was detected in plasma from control rats. The concentrations of IN-B2856 reported for 4500 ppm females were greater than those reported for the 18000 ppm females, although all concentrations were very low (close to the limit of detection). The reason for this could be that samples from different groups were analysed on different days, and the fact that the instrument responses were greater on the day the 4500 ppm rat plasma samples were analysed resulting in better quantitation, which is very common for LC/MS instruments. The standard deviation (± 0.26) for the 4500 ppm female samples indicates these results were not statistically significantly different from the 18000 ppm female samples.

Collectively, these analytical results of urine and plasma samples from rats exposed to INMCX20 confirm

that this test substance is metabolised to small quantities of IN-B2856 and INEY252.

I. NECROPSY

There was no test substance-related mortality. A single male rat from the intermediate high-dose group (4500 ppm) was found dead on day 42. Important macroscopic findings were nose fracture and red discoloration of the stomach. The death was considered accidental and unrelated to test substance administration. All other rats survived until scheduled termination.

Organ weights

There were no treatment-related organ weight changes following the exposure period.

Gross pathology

At the terminal sacrifice, there were no treatment-related macroscopic findings.

Histopathology

Following the dosing phase, there were no treatment-related microscopic findings. Subacute/chronic inflammation, biliary hyperplasia and cholangio-fibrosis in the liver of a single intermediate high-dose male rat were considered spontaneous and incidental with no apparent relationship to the test substance exposure.

III. CONCLUSIONS

The no-observed-adverse-effect level (NOAEL) for male and female rats was 18000 ppm, equivalent to 1157 and 1461 mg/kg bw/day in males and females, respectively. The NOAEL is based on a lack of adverse, test substance-related effects in either sex at 18000 ppm, the highest concentration tested.

3. Assessment and conclusion

Assessment and conclusion by applicant:

Statistically significantly lower overall mean body weight gain (86 % of control) was observed in 18000 ppm males but was not considered adverse as it was not associated with a statistically significant difference in mean final body weight or in overall mean food consumption or food efficiency.

Despite the deviations in clinical chemistry (LDL, HDL, T3, T4 and TSH not determined), organ weights (prostate + seminal vesicles and coagulating glands), thyroid and pituitary gland not determined) and histopathology (cervix, coagulating glands, gall bladder and male mammary glands not examined) this study was conducted under GLP and was considered to be valid.

Therefore, the no-observed-adverse-effect level (NOAEL) for male and female rats was 18000 ppm, equivalent to 1157 and 1461 mg/kg bw/day in males and females, respectively. The NOAEL is based on a lack of adverse, test substance-related effects in either sex at 18000 ppm, the highest concentration tested.

Further, the study provides additional information about metabolism of N-acetyl glyphosate. It was shown that N-acetyl glyphosate was marginally metabolised to glyphosate and N-acetyl AMPA, as only very small quantities (close to LOD) were detected in urine and plasma samples at day 82/83.

Assessment and conclusion by RMS:

Genotoxicity

Guidelines followed in study	OECD 471 (1997)
Deviations from current test guideline	None
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

N-acetyl-glyphosate sodium salt (batch: 123K5012, purity: 84.3 % as sodium salt; 67.4 % as free acid) metabolite of glyphosate, was assessed for gene mutation in bacteria (Ames test). *Salmonella typhimurium* strains TA 98, TA 100, TA 1535 and TA 1537 and *Escherichia coli* strain WP2 uvrA were exposed to the test item, solvent (deionised water) and appropriate positive controls in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). Dose levels were selected based on the results of a preliminary toxicity test in strain TA98, in which no cytotoxicity was observed up to 5000 µg/plate.

In the main mutagenicity study, two independent standard plate tests (plate incorporation method) were performed. Test item concentrations were in the range of 100 – 5000 µg/plate. After an incubation period of 52 ± 4 hours at 37 ± 2 °C, the bacterial background lawn was examined and the number of his^+ or trp^+ revertant colonies were counted.

There was no precipitation and no cytotoxicity observed for any tester strain at any concentration, neither in the presence nor in the absence of S9 mix.

In the first experiment, no increase in the mean number of revertant colonies was observed for any tester strain at any concentration, neither with nor without metabolic activation. In the confirmatory experiment, there was a 3.3-fold increase in the number of revertant colonies for strain TA 1537 in the absence of S9 mix. The increase was not dose-related and did not meet the criteria for a positive evaluation, therefore the observation was considered to be incidental. In addition, the mean value of spontaneous revertants obtained for the vehicle control with strain TA 98 in the absence of S9 mix was not within the acceptable range specified in the protocol. Therefore, a third experiment was performed for strain TA 98 in the absence of S9 mix. In the repeat mutagenicity test, all data were acceptable and there was no positive increase in the mean number of revertants per plate. In addition, the number of spontaneous revertants induced by the solvent control was as expected for all other strains in both experiments.

The number of revertant colonies induced by the positive controls were within the range of the laboratories historical control data, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

Based on the experimental findings, N-acetyl-glyphosate sodium salt, metabolite of glyphosate, did not induce gene mutations in bacteria and is therefore considered negative in the Ames standard plate test in the presence and absence of metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material: N-acetyl-glyphosate, sodium salt

Identification: Not specified

Description: White powder

Lot/Batch number: 123K5012

Purity: 84.3 % (N-acetyl-glyphosate sodium salt) and 67.4 % (N-acetyl-glyphosate as free acid)

Stability of test compound: The stability of the test item at storage conditions (at room temperature with desiccant) and the stability of the test item in solvent was not specified.

Solvent (vehicle) used: Deionised water

2. Control materials:

Negative control: A negative control was not employed in this study.

Solvent (vehicle) control: Deionised water

Solvent (vehicle)/final concentration: 0.05 mL per plate

Positive controls: Please refer to table below.

Strain	Metabolic activation	Mutagen	Conc. [µg/plate]
S. typhimurium strains			
TA 98	-S9	2-Nitrofluorene	1.0
	+S9	Benzo[a]pyrene	2.5
TA 100	-S9	Sodium azide	2.0
	+S9	2-Aminoanthracene	2.5
TA 1535	-S9	Sodium azide	2.0
	+S9	2-Aminoanthracene	2.5
TA 1537	-S9	ICR-191	2.0
	+S9	2-Aminoanthracene	2.5
E. coli strains			
WP2 uvrA	-S9	4-Nitroquinoline-N-oxide	1.0
	+S9	2-Aminoanthracene	25.0

3. Metabolic activation:

S9 mix was purchased from [redacted]. (Lot no. 1615 and 1626). The homogenate was prepared from the livers of male Sprague-Dawley rats that had been induced with a single intraperitoneal injection of Aroclor 1254 at a dose of 500 mg/kg bw. The S9 mix was thawed prior to each experiment and co-factors were immediately added to prepare S9 mix containing the following components:

S9 mix component	Concentration	Unit
Phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	10	% (v/v)

4. Test organisms:

Tester strains				Bacteria batch checked for	
S. typhimurium		*E.coli*			
TA 98	✓	WP2 uvrA	✓	deep rough character (rfa)	✓
TA 100	✓	WP2 uvrA (pKM101)		ampicillin resistance (R factor plasmid)	✓
TA 1535	✓			UV-light sensitivity (absence of uvrB and uvrA genes in *S. typhimurium* and *E. coli* strains, respectively)	✓
TA 1537	✓				
TA 1538				Histidine auxotrophy (automatically via the spontaneous rate)	✓

5. Test concentrations:

(e) Preliminary cytotoxicity assay:

Plate incorporation test ± S9 mix:	
Concentrations:	*6.67 - 5000 µg/plate**
Tester strains:	TA100 and WP2 uvrA
Replicates:	*One plate was used for each condition.*

*: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 67.4 %.

(f) Mutation assays:

Plate incorporation test ± S9 mix:	
Concentrations:	*100, 333, 1000, 3000 and 5000 µg/plate**
Tester strains:	TA 98, TA 100, TA 1535, TA 1537 and WP2 uvrA
Replicates:	*Triplicates*

*: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 67.4 %.

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 15 Mar – 04 May 2004
Finalisation date: 23 Dec 2004

2. Standard plate test (plate-incorporation test, SPT):
In tests with metabolic activation, an aliquot of 50 µL test solution, vehicle (deionized water) or positive control, an aliquot of 0.1 mL fresh bacterial culture and 0.5 mL S9 mix were added to 2 mL of molten top agar (supplemented with 0.5 mM histidine + 0.5 mM biotin or 0.5 mM tryptophan). In tests without metabolic action, 50 µL test solution, vehicle (deionized water) or positive control and 0.1 mL fresh bacterial culture were added to 2.5 mL of molten top agar. Afterwards, the mixture was vortexed and overlaid onto the surface of minimal bottom agar plates. After solidification, the plates were inverted and incubated for 52 ± 4 hours at 37 ± 2 °C. Each concentration and the controls were tested in triplicates. Following incubation, the bacterial background lawn was examined and the number of his^+ or trp^+ revertants colonies were counted.

3. Cytotoxicity
Toxicity was detected by a

- reduction in the number of spontaneous revertants
- clearing or diminution of the background lawn (= reduced his^- or trp^- background growth)

and recorded for all test groups both with and without S9 mix in all experiments.

4. Statistics

For all replicate platings, the mean revertants per plate and the standard deviations were calculated. No further statistical analysis was performed.

5. Acceptance criteria

The assay was considered valid if the following criteria were met:

- The tester strain cultures exhibited a characteristic number of spontaneous revertants per plate when treated with the solvent control. The acceptable ranges for the mean vehicle controls were 8 – 60 for TA 98, 60 – 240 for TA 100, 4 – 45 for TA 1535, 2 – 25 for TA 1537 and 5 – 40 for WP2 uvrA.
- The density of the tester strain cultures was ≥ 0.5 x 10^9 bacteria per mL and/ or had reached a target level of turbidity demonstrated to produce cultures with a density ≥ 0.5 x 10^9 bacteria per mL.
- The mean number of revertants induced by the positive controls were increased at least 3-fold over the mean value of the vehicle control for that strain.
- A minimum of three non-toxic concentrations was required to evaluate the assay data.

6. Evaluation criteria

A test item was considered positive (mutagenic) in the assay if the following criteria were met:

- There was an at least 2-fold increase in the mean number of revertant colonies per plate in at least one tester strain when compared to the appropriate vehicle control for tester strains TA 98, TA 100 and WP2 uvrA.
- There was an at least 3-fold increase in the mean number of revertant colonies per plate in at least one tester strain when compared to the appropriate vehicle control for tester strains TA 1535 and TA 1537.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

Analytical determinations were not performed in the study.

B. CYTOTOXICITY

In the preliminary toxicity test, as well as in the main mutagenicity study, no cytotoxicity was observed with any tester strain up to the highest concentration of 5000 µg/plate, neither with nor without metabolic activation.

C. SOLUBILITY

Precipitation was not observed in any tester strain, at any concentration, neither with nor without S9 mix.

D. MUTATION ASSAY

In the first experiment, there was no increase in the number of his^+ or trp^+ revertant colonies observed for any strain at any concentration, neither in the presence nor in the absence of S9 mix. In the confirmatory experiment, there was a 3.3-fold increase in the number of revertant colonies for strain TA 1537 in the absence of S9 mix. The increase was not dose-related and did not meet the criteria for a positive evaluation, therefore the observation was considered to be incidental. In addition, the mean value of spontaneous revertants obtained for the vehicle control with strain TA 98 in the absence of S9 mix was not within the acceptable range specified in the protocol. Therefore, a third experiment was performed for strain TA 98 in the absence of S9 mix. In the repeat mutagenicity test, all data were acceptable and there was no positive increase in the mean number of revertants per plate. In addition, the number of spontaneous revertants induced by the solvent control was as expected for all other strains in both experiments.

The number of revertant colonies induced by the positive controls were within the range of the laboratories historical control data, demonstrating the functionality of the metabolic activation system and the sensitivity of the test.

III. CONCLUSIONS

Under the conditions of the present study, N-acetyl glyphosate sodium salt, metabolite of glyphosate, was negative for gene mutation in the Ames standard plate test in the presence and absence of metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, N-acetyl glyphosate sodium salt was negative for gene mutation in bacteria (*S. typhimurium* TA 98, TA 100, TA 1535, TA 1537 and *E. coli* WP2 uvrA) with and without metabolic activation.
The study was conducted in compliance with GLP and according to OECD guideline 471 (1997), The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/042

1. Information on the study

Data point	CA 5.8.1/042
Report author	[redacted]
Report year	2004
Report title	Chromosomal Aberrations in Chinese Hamster Ovary (CHO) Cells

Report No	7535-102
Document No	VER04-COV-02
Guidelines followed in study	OECD 473 (1997)
Deviations from current test guideline	Only 200 cells in metaphase were evaluated, whereas the currently valid OECD 473 (2016) recommends the evaluation of 300 metaphase cells per condition. In addition, cytotoxicity was evaluated based on mitotic indices, which is not recommended for cell lines. Evaluation criteria specified in the study report were inconsistent with those specified in the guideline.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

N-acetyl-glyphosate, sodium salt (batch: 123K5012, purity: 84.3 % as sodium salt; 67.4 % as free acid), metabolite of glyphosate, was investigated in a chromosome aberration test in Chinese hamster ovary (CHO) cells. Duplicate cultures were exposed to the test item, negative (medium), solvent (water) and positive controls (mitomycin C in the absence of S9 mix and cyclophosphamide in the presence of S9 mix) in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). Test item concentrations in the range of 10 – 2800 µg/mL were screened for cytotoxicity by visual inspection, prior to selection of concentration levels used for chromosome analysis in the range of 960 – 2800 µg/mL.

The cells were treated for 3 hours in the presence and absence of metabolic activation and for 20 hours in the absence of metabolic activation at 37 ± 2 °C. In the 3-hour treatment schedule, the cells were washed following exposure and re-incubated afterwards. All cultures were harvested 20 hours after start of exposure and chromosome preparations were made. A total of 200 metaphases per condition (100 metaphases per culture) were scored for structural chromosome aberrations. In addition, the percentage of polyploid and endoreduplicate cells was scored among 100 metaphases. Cytotoxicity was assessed as mitotic index and evaluated for 1000 cells per culture.

Precipitation of the test item in solvent or medium was not observed for any concentration, neither in the presence nor absence of S9 mix and independent of the treatment period. Cytotoxicity, evident as a slight reduction of the mitotic index, was observed after 3 hours of exposure at 1960 and 2800 µg/mL in the absence of S9 mix.

There was no statistically significant increase in the number of cells with chromosomal aberrations observed in any experiment at any concentration when compared to vehicle controls, neither in the presence nor in the absence of S9 mix. In addition, there was no increase in the frequency of cells in polyploidy and endoreduplication for any condition.

The frequency of aberrant metaphases in the negative, solvent and positive control cultures were within the range of the laboratory's historical control data, demonstrating the sensitivity of the test and the functionality of the S9 mix.

Based on the experimental results obtained in the present study, N-acetyl-glyphosate, sodium salt, metabolite of glyphosate, did not induce chromosomal aberrations in CHO cells *in vitro*, neither in the presence, nor in the absence of metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test N-acetyl-glyphosate sodium salt

material:

Identification:	Not specified
Description:	White powder
Lot/Batch #:	123K5012
Purity:	84.3 % (N-acetyl-glyphosate, sodium salt) and 67.4 % (N-acetyl-glyphosate as free acid)
Stability of test compound:	The stability of the test item under storage conditions (at room temperature with desiccant) was guaranteed until the expiry date 10 Feb 2006. The stability of the test item in solvent was at the responsibility of the sponsor.
Solvent (vehicle) used:	Water

2. Control Materials:

Negative control:	Culture medium
Solvent (vehicle) control:	Cell culture grade water (CCGW)
Positive control:	-S9 mix: Mitomycin C (MMC): 0.75 and 1.5 µg/mL for the 3-h treatment, 0.2 and 0.4 µg/mL for the 20-h treatment, respectively +S9 mix: Cyclophosphamide (CP): 7.5* and 12.5 µg/mL (* analysed for chromosomal aberrations)

3. Metabolic activation:

The metabolic activation system consisted of a rat liver post-mitochondrial fraction (S9 mix) and an energy producing system (NADP plus isocitric acid).
S9 mix was routinely prepared from the livers of rats, which received a single intraperitoneal injection of 500 mg/kg bw Aroclor 1254. Five days after treatment, the animals were sacrificed and the S9 homogenates were isolated. The metabolic activation system was prepared immediately before the experiment as follows:

S9 mix component	Concentration	Unit
Isocitric acid	10.5	mM
NADP, sodium salt	1.8	mM
S9	1.5	% (v/v)

4. Test organism:

Chinese hamster ovary (CHO) cells were used, established from an ovarian biopsy of a female Chinese hamster. The cell line was obtained from the laboratory of [redacted] and sub-cloned in the testing laboratory. Stock cultures were stored in liquid nitrogen. The cell line has an average cell cycle time of 12 – 14 hours and a modal chromosome number of 21. Stock cultures were maintained for up to 8 weeks after thawing. Twice during this period, the cells were screened for mycoplasma contamination.

5. Cell culture:

Medium: McCoy's 5a culture medium supplemented with 10 % heat-inactivated fetal bovine serum, 2 mM L-glutamine, 100 U/mL penicillin G and 100 µg/mL streptomycin.

Incubation: *Cultures were incubated with loose caps in a humidified incubator at 37 ± 2 °C in an atmosphere of 5 ± 1.5 % CO_2 in the air.*

Cell culture establishment prior to exposure: *Cultures were initiated by seeding approx. 0.9 x 10^6 cells per 75 cm^2 flask 24 hours prior to treatment.*

6. Test concentrations and number of replicates:

Metabolic activation	Duration of exposure (Fixation time)	Concentrations§	Replicates
-S9 mix	3 h (20 h)	10.0, 19.0, 27.1, 38.8, 55.4, 79.1, 113, 161, 231, 329, 471, 672, 960*, 1370*, 1960* and 2800*# µg/mL	Duplicate
-S9 mix	20 h (20 h)	10.0, 19.0, 27.1, 38.8, 55.4, 79.1, 113, 161, 231, 329, 471, 672, 960*, 1370*, 1960* and 2800*# µg/mL	Duplicate
+S9 mix	3 h (20 h)	10.0, 19.0, 27.1, 38.8, 55.4, 79.1, 113, 161, 231, 329, 471, 672, 960*, 1370*, 1960* and 2800*# µg/mL	Duplicate

* Samples analysed for chromosomal aberrations; #: corresponding to > 10 mM of the free acid
§: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 67.4 %.

B. STUDY DESIGN AND METHODS

2. Dates of experimental work: 16 Mar – 22 Apr 2004
Finalisation date: 10 Sep 2004

3. Main cytogenicity test:

Treatment: Following cell culture establishment, duplicate cultures per condition were exposed to the test item, negative (culture medium), solvent (water) or positive control (mitomycin C in the absence of S9 mix and cyclophosphamide in the presence of S9 mix) in the presence and absence of metabolic activation.
The cells were treated for 3 hours with and without S9 mix and for 20 hours without S9 mix. After the 3-hour treatment period in the presence and absence of S9 mix, the cultures were washed with buffered saline, re-fed with culture medium and incubated for the remaining 17 hours until harvest. For the 20-hour treatment period in the absence of S9 mix, cells were harvested immediately following treatment.

Spindle inhibition: During the last 2 ± 0.5 hours of cultivation, cell division was arrested by addition of 0.1 µg/mL Colcemid to each culture.

Cell harvest: The cell cultures were trypsinised to collect mitotic and interphase cells. The

cells were swollen in 75 mM potassium chloride and fixed in methanol : glacial acetic acid (3 : 1 v/v) fixative.

Slide preparation: Fixed cells were dropped on glass slides and air-dried. The slides were stained with 5 % Giemsa solution, then air-dried and mounted permanently.

Metaphase analysis: A total number of 200 metaphase cells per condition (100 metaphase cells per culture) were examined by microscopy. Cells were selected for good morphology and only cells with the number of centromers equal to the model number 21 ± 2 (range 19 – 23) were evaluated. At least 25 cells were analysed from those cultures that had greater than 25 % of cells with one or more aberrations. The cells were analysed for different type of chromosome and chromatide aberrations, including gaps, breaks and complex exchanges. The percentage of polyploid and endoreduplicate cells was scored among 100 metaphases.

Cytotoxicity: Prior to harvest of the cultures, visual observations of cytotoxicity were made, including the assessment of confluency and the presence of mitotic (large, rounded cells) and dead, floating cells.
At scoring, the mitotic index of each culture was calculated based on the number of cells in metaphase observed per 1000 cells scored.

4. Statistics

The number and percentage of aberrant cells including and excluding gaps was analysed using a Cochran-Armitage test for linear trend and a Fisher's Exact test. The percentage of cells with aberrations in treated cells was compared to the results obtained for the vehicle control.
Statistical analysis was also performed for cells exhibiting polyploidy and/or endoreduplication in order to indicate significant events as indicators of possible induction of numerical aberrations; however, the test articles were evaluated only for structural aberrations and not for numerical aberrations in the protocol.

5. Acceptance criteria

The chromosome aberration test was considered acceptable if the following criteria were met:

- The vehicle control cultures contained less than approximately 5 % cells with aberrations.
- The positive control result was significantly higher than the vehicle control ($p \leq 0.01$).
- If the aberration results were negative and there was no significant reduction (≥ 50 %) in the mitotic index, the highest applicable dose (10 mM or 5 mg/mL) or a dose exceeding the solubility limit in culture medium must have been included.
- At least 3 dose levels for analysis of chromosome aberrations were included.

6. Evaluation criteria

A test substance was considered positive (clastogenic) in the chromosome aberration test if the following criteria were met:

- There was a significant increase in the number of cells with chromosomal aberrations observed at one or more concentrations.
- The linear trend evaluated the dose responsiveness. A dose-response was observed if a significant increase was seen at one or more concentrations.

A test substance was considered negative (not clastogenic) in the chromosome aberration test if no significant increase in the number of cells with chromosomal aberrations was observed at any

concentration.

II. RESULTS AND DISCUSSION

A. ANALYTCAL DETERMINATIONS

Analytical determinations of the test substance in the solvent were not perfomed.

B. CYTOTOXICITY

Visual inspection of the cultures prior to harvest revealed no indication of cytotoxic effects. Cytotoxicity, evident as a slight reduction of the mitotic index, was observed after 3 hours of exposure for the two highest concentrations in the absence of S9 mix. The mitotic indices were reduced by 20 and 15 % at 1960 and 2800 µg/mL, respectively. There was no cytotoxicity at any concentration after exposure for 3 hours in the presence of S9 mix or after 20 hours of exposure in the absence of S9 mix.

C. SOLUBILITY

Precipitation of the test item in vehicle or culture medium was not observed for any condition, up to the highest tested concentration, neither in the presence, nor in the absence of metabolic activation.

D. CYTOGENICITY

There was no statistically significant increase in the number of cells with chromosomal aberrations observed in any experiment at any concentration when compared to vehicle controls, neither in the presence nor in the absence of S9 mix. In addition, there was no increase in the frequency of cells in polyploidy and endoreduplication for any condition.

The frequency of aberrant metaphases in the negative, solvent and positive control cultures were within the range of the laboratory's historical control data, demonstrating the sensitivity of the test and the functionality of the S9 mix.

Table 5.8.1-103: Results of the cytogenicity test obtained with N-acetyl-glyphosate, sodium salt, metabolite of glyphosate, after 3 hours of exposure in the presence and absence of S9 mix and after 20 hours of exposure in the absence of S9 mix ([redacted] 2004)

III. CONCLUSIONS

Under the conditions of the test, N-acetyl-glyphosate, sodium salt, metabolite of glyphosate, has no clastogenic potential in Chinese hamster ovary (CHO) cells, neither in the presence nor in the absence of metabolic activation.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, N-acetyl-glyphosate, sodium salt was negative for induction of chromosomal aberrations in Chinese hamster ovary (CHO) cells with and without metabolic activation.
The test was performed under GLP conditions and in accordance with OECD guideline 473 (1997). There were only minor deviations when compared to OECD 473 (2016). The number of metaphases investigated was only 200, which was the number to be investigated recommended by the previous OCED 473 (1997). The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/043

1. Information on the study

Data point	CA 5.8.1/043
Report author	[redacted]
Report year	2006
Report title	In Vitro Mammalian Cell Gene Mutation Test (CHO/HGPRT)
Report No	DuPont-20155
Document No	-
Guidelines followed in study	OECD 476 (1997), US EPA OPPTS 870.5300, EC Commission Directive 2000/32/EC Annex 4E-B17 (2000), JMAFF (1985)
Deviations from current test guideline	The newly introduced cytotoxicity parameter RS (relative survival) in OECD 476 (2016) and the adjusted cloning efficiency were not re-calculated, since no data on the number of cells after treatment were provided. In the current study, cytotoxicity was evaluated based on cloning efficiency after treatment (CE_1, survival) and after selection (CE_2, viability), in accordance with the previous guideline version.

Previous evaluation	No, not previously submitted

2. Full summary

Executive summary

Disodium N-acetyl-N-(phosphonomethyl)glycine (IN-MCX20, batch: IN-MCX20-002, purity: 63 %) was tested *in vitro* for its ability to induce forward mutations in mammalian cells by assessing the mutation of the HPRT locus in Chinese hamster ovary (CHO K_1) cells. Duplicate cultures were exposed to the test item, solvent (water) and positive controls (ethylmethane sulfonate for cultures without S9 mix and benzo(a)pyrene for cultures with S9 mix) in the presence and absence of metabolic activation (Aroclor 1254-induced rat liver S9 fraction). Based on the results of a preliminary toxicity test, in which no substantial cytotoxicity was observed up to 2091 µg/mL (corresponding to 10 mM) with and without S9 mix, the concentrations for the main mutagenicity study were selected.

Test item concentrations in the range of 250 – 2091 µg/mL were used. After 5 hours of exposure with and without S9 mix, the cells were incubated for 7 days to allow expression of the mutant phenotype. The expression period was followed by a selection period, in which the cells were cultivated in medium supplemented with 6-thioguanidine for 9 days. Cytotoxicity was assessed as relative survival and relative viability after the expression and selection period, respectively.

There was no precipitation of the test item in solvent and in culture medium, neither in the presence nor absence of S9 mix. In addition, cytotoxicity, evident as a cloning efficiency ≤ 50 %) was not observed for any condition at any concentration. The relative cloning efficiency at the highest concentration of 2091 µg/mL was 115 % without S9 mix and 123 % with S9 mix. pH and osmolality were within an acceptable range.

Treatment with Disodium N-acetyl-N-(phosphonomethyl)glycine did not induce a significant increase in the number of mutant colonies at any concentration, neither in the presence nor in the absence of metabolic activation. For all conditions and at all dose levels, mutant frequencies were below the minimum value for a positive response.

Mutant frequencies of the control cultures remained within the range of the laboratory's historical control data. The positive control mutagens ethylmethane sulfonate and benzo(a)pyrene induced mutant frequencies that were at least 3-fold above those of vehicle controls, demonstrating the functionality of the S9 mix and the sensitivity of the test.

Under the conditions of the test, there was no evidence for gene mutation in CHO-K_1 cells *in vitro*, neither in the presence nor in the absence of metabolic activation.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Disodium N-acetyl-N-(phosphonomethyl)glycine
Identification:	IN-MCX20
Description:	White solid
Lot/Batch number:	IN-MCX20-002
Purity:	63 %
Stability of test compound:	The stability of the test item at storage conditions (under nitrogen in a desiccator) was guaranteed until the expiry date 25 Apr 2009. The stability of the test substance in vehicle was confirmed by analytical methods.

2. Control material:

Negative control: The negative control was actually the solvent control.
Solvent (vehicle) control: Water
Positive control: - S9 mix: Ethylmethane sulfonate (EMS), 0.2 µL/mL in DMSO
+ S9 mix Benzo(a)pyrene (BaP), 4 µg/mL in DMSO

3. Metabolic activation:

S9 mix was purchased from [redacted] ([redacted]). The liver homogenate was produced from the livers of male Sprague-Dawley rats that were induced with Aroclor 1254. Immediately prior to use the S9 liver homogenate was thawed and mixed with co-factors as follows:

S9 mix component	Concentration	Unit
Sodium phosphate buffer (pH 7.4)	100	mM
KCl	33	mM
NADPH-generating system		
Glucose 6-phosphate	5	mM
NADP	4	mM
$MgCl_2$	8	mM
S9	10	% (v/v)

4. Test organism:

Chinese hamster ovary (CHO-K_1) cells were obtained from American Type Culture Collection (ATCC) in Manassas, Virginia, USA. The cell stocks were stored in liquid nitrogen and routinely tested for mycoplasma contamination. Cells used in the mutation assay were within three to four subpassages from cleansing in pre-treatment medium supplemented with hypoxanthine, aminopterin and thymidine (HAT) in order to assure karyotypic stability.

5. Cell culture media:

Pre-treatment medium (HAT medium): Ham's F12 medium supplemented with hypoxanthine, aminopterin and thymidine

Cultivation medium (F12FBS5-Hx): Ham's F12 medium, supplemented with 5 % dialysed fetal bovine serum, 100 U/mL penicillin and 100 µg/mL streptomycin

Treatment medium (±S9): *Cultivation medium (F12FBS5-Hx)*

Selection medium: Cultivation medium (F12FBS5-Hx) supplemented with 10 µM 6-thioguanidine (6TG)

Incubation: *At 37.5 ± 2 °C in a humidified atmosphere of 5 ± 2 % CO_2*

6. Locus examined: Hypoxanthin guanine phosphoribosyltransferase (HGPRT)

7. Test concentrations and number of replicates:

(a) Preliminary cytotoxicity and mutagenicity test:

Metabolic activation	Duration of exposure	Concentrations[§]	Replicates
± S9 mix	5 h	25, 50, 100, 250, 500, 750, 1000, 1500 and 2091[#] µg/mL	Triplicate plates from a single culture

[§]: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 1.59.
[#]: corresponding to a concentration of 10 mM

(b) Main gene mutation test:

Metabolic activation	Duration of exposure	Concentrations[§]	Replicates
± S9 mix	5 h	250, 500, 1000, 1500 and 2091[#] µg/mL	Triplicate plates from duplicate cultures

[§]: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor of 1.59.
[#]: corresponding to a concentration of 10 mM

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 22 Jun – 03 Aug 2006
Finalisation date: 13 Sep 2006

2. Preliminary cytotoxicity and mutagenicity test:
A preliminary test was performed to identify suitable dose levels for the main mutagenicity study. Cell cultures were established identically to the performance in the main mutagenicity test described below. The cells were exposed to nine test substance concentrations in the range of 25 - 2091 µg/mL for 5 hours in the presence and absence of S9 mix at 37 ± 2 °C. The highest concentration was equivalent to a 10 mM concentration. Following exposure, the cells were washed with Hank's Balanced Salt Solution (HBSS), re-incubated in fresh culture medium for approx. 20 hours, harvested and plated for determination of cell survival (cloning efficiency 1). After incubation for 7 days, the formed colonies were fixed, stained and counted.
Based on the results of the preliminary test, the test item concentrations for the main mutagenicity test were selected.

3. Main mutation assay:
Pre-treatment of cells:
For each test group, 5 x 10^5 cells were seeded into 25 cm^2 flasks and incubated for 16 - 24 hours prior to treatment.

Treatment:
On the day of treatment, the medium was exchanged. For treatment in the presence of S9 mix, 20 % of the medium were replaced by S9 mix. Duplicate cultures were exposed to the test item, vehicle (water) and positive controls (0.2 µL/mL ethylmethane sulfonate without S9 mix and 4 µg/mL benzo(a)pyrene with S9 mix) for 5 hours in the presence and absence of metabolic activation at 37 ± 2 °C. Test item concentrations ranged from 250 - 2091 µg/mL. Following exposure, the cells were washed with Hank's Buffered Salt Solution (HBSS) and the culturing was continued for another 18 – 24 hours. After the incubation period, the cells were trypsinised and counted. Triplicates of 100 cells/ 60 mm dish were seeded for the determination of survival (cloning efficiency 1) and duplicate cultures with ≤ 10^6 cells/ 100 mm dish were seeded for the expression of the mutant phenotype.

Expression period:
After treatment, duplicate cultures with ≤ 10^6 cells/ 100 mm dish were seeded and sub-cultured at 2-3 day intervals for a 7-day expression period. After the expression period, each culture was divided. Triplicates of 100 cells/ 60 mm dish were seeded for the determination of viability (cloning efficiency 2) and five culture dishes with 2 x 10^5 cells/ 100 mm dish were seeded for the selection of mutants.

Selection period:
For the selection of mutants, five culture dishes with 2 x 10^5 cells/ 100 mm dish were seeded in medium enriched with 10 µM 6-thioguanidine (selection medium). After an incubation period of 9 days, the colonies were fixed, stained and counted.

4. Cytotoxicity:

Cloning efficiency CE_1 (survival)
The survival (cloning efficiency 1) of test item-treated cells relative to solvent controls was determined in parallel to the mutagenicity test. At the end of the exposure period, a sample of each cell culture was collected to assess survival of the cells. Triplicates of 100 cells/ 60 mm dish were seeded and incubated for 8 days. Afterwards, the colonies were fixed, stained and counted.

Cloning efficiency CE_2 (viability)
The viability (cloning efficiency 2) was determined in parallel to the selection of mutants. After the expression period, triplicates of 100 cells/ 60 mm dish were seeded in medium without 6-thioguanine to assess cell viability. After an incubation period of 9 days, the developed colonies were fixed, stained and counted.

5. Evaluation:

Cytotoxicity (cloning efficiency CE)
The number of colonies divided by the number of cells plated was calculated for each sample. The absolute cloning efficiency was determined for each test group, as well as the relative cloning efficiency in comparison to the solvent control group.

CE_1 (survival)
The cytotoxicity of the test substance after the exposure period was determined for each test group and is indicated as absolute and relative cloning efficiency (CE_1 and RCE_1, respectively).

CE_2 (viability)
The cytotoxicity of the test substance at the end of the expression period was determined for each test group and is given as absolute and relative cloning efficiency (CE_2 and RCE_2, respectively).

The cloning efficiency (CE, %) was calculated for each test group as follows:

$$CE_{absolute} = \frac{\text{Total number of colonies}}{\text{Total number of cells plated}} \times 100$$

$$RCE_x = \frac{CE_{absolute} \text{ of the test group}}{CE_{absolute} \text{ of the vehicle control group}} \times 100$$

Mutant frequency (MF)
The cloning efficiency of mutant colonies in selective medium divided by the cloning efficiency in non-selective medium measured for the same culture at the time of selection was calculated for each sample.

Uncorrected mutant frequency:
The uncorrected mutant frequency (MF_{uncorr}) was calculated for each test group as follows:

$$\text{MF uncorrected} = \frac{\text{Total number of mutant colonies}}{\text{Number of seeded cells}} \times 10^6$$

Corrected mutant frequency

The corrected mutation frequency (MF_{corr}) was calculated regarding the values of CE_2:

$$\text{MF corrected} = \frac{\text{MF uncorrected}}{CE_2} \times 100$$

6. Statistics:
Statistical analysis was not performed.

7. Acceptance criteria:
The test was considered valid if the following criteria were met:

- The cloning efficiency of the vehicle control was > 50 % with a spontaneous mutant frequency within the range of the laboratories historical control data.
- The mutant frequency of the positive control was at least 3-fold as compared to the concurrent vehicle control and exceeded 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data).
- At least 4 analysable concentrations showing mutants were required for evaluation.

8. 8. Evaluation criteria:
A test item was judged positive for gene mutation in mammalian cells if the following criteria were met:

- A mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at 2 or more consecutive concentrations of the test substance when compared to the solvent control.
- The observed increase in mutant frequency was accompanied by a concentration-related increase.
- A mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at the highest concentration only.

The test item was judged equivocal if a mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was observed at any dose level other than the highest concentration.

The test item was judged negative for gene mutation in mammalian cells if a mutant frequency of > 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) was not observed at any dose level.

II. RESULTS AND DISCUSSION

1. ANALYTICAL DETERMINATIONS

Analytical determinations were performed for formulations 2.5, 10 and 20.91 mg/mL using a high performance liquid chromatography (HPLC) with MS/MS detection. The test item formulations were ± 15.6 % of the nominal concentrations, thus the test item was considered to be present at acceptable concentrations in the dosing solutions. In addition, the formulations were shown to be uniformely mixed (Coefficient of variation (CV) = 1, 2 and 4 % for 2.5, 10 and 20.91 mg/mL, respectively. There was no test substance in the 0 mg/mL sample. Stability of the test item in vehicle was confirmed for 5 hours at room temperature.

2. CYTOTOXICITY

In the preliminary cytotoxicity test, no cytotoxicity, evident as a clonig efficiency of ≤ 50 %, was observed. The relative cloning efficiency at the highest test item concentration (2091 µg/mL) was 78 % in the absence of S9 mix and 95 % in the presence of S9 mix. Osmolality and pH measurements of test

substance in medium at 2091 µg/mL were found to be within an acceptable range. Based on these findings, the concentrations for the main mutagenicity study were selected to be in the range of 250 – 2091 µg/mL, corresponding to 1.2 – 10 mM.
In the main mutagenicity experiment, there was as well no cytotoxicity observed at any dose level, neither in the presence nor absence of S9 mix. The relative cloning efficiency at the highest concentration of 2091 µg/mL was 115 % without S9 mix and 123 % with S9 mix. The pH in activated (+S9) and non-activated (-S9) cultures was 7.36 and 7.69 and comparable to the pH of solvent controls (7.45 and 8.04 in cultures with and without S9 mix, respectively). The observed changes in osmolality were ≤ 20 % and not considered significant.

3. SOLUBILITY

There was no precipitation observed up to the highest concentration tested, neither in the presence, nor absence of metabolic activation.

4. MUTANT FREQUENCY

Treatment with Disodium N-acetyl-N-(phsphonomethyl)glycine did not induce a significant increase in the number of mutant colonies at any concentration, neither in the presence nor in the absence of metabolic activation. For all conditions and at all dose levels, mutant frequencies were below 40 mutants per 10^6 cells (minimum value for the positive control in the laboratories historical control data) and no dose-response relationship was evident.
Mutant frequencies of the solvent control cultures remained within the range of the laboratories historical control data. The positive control mutagens ethylmethane sulfonate and benzo(a)pyrene induced mutant frequencies that were at least 3-fold above those of vehicle controls, demonstrating the functionality of the S9 mix and the sensitivity of the test.

III. CONCLUSIONS

Based on the experimental findings and under the conditions of the test, Disodium N-acetyl-N-(phosphonomethyl)glycine did not induce gene mutations in the HGPRT locus of CHO-K_1 cells, neither in the presence nor in the absence of metabolic activation and is therefore considered negative for mutagenicity in mammalian cells *in vitro*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, Disodium N-acetyl-N-(phosphonomethyl)glycine was negative for mutagenicity at the HGPRT locus in CHO-K_1 cells with and without metabolic activation.
The study was conducted in compliance with GLP and according to OECD guideline 476 (1997). There were only minor deviations when compared to OECD 476 (2016), which were considered to not compromise the validity of the study. The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.1/044

1. Information on the study

Data point	CA 5.8.1/044
Report author	[redacted]

Report year	2006
Report title	IN-MCX20: Mouse Bone Marrow Micronucleus Test
Report No	[redacted]-20154
Document No	-
Guidelines followed in study	OECD 474 (1997), US EPA OPPTS 870.5395 (1998), EEC Directive 2000/32/EC B12 (2000), JMAFF 12 Nousan (2000)
Deviations from current test guideline	According to the current guideline OECD 474 (2016), at least 4000 polychromatic erythrocytes per animal should be evaluated for the presence of micronuclei. However, in the present study only 2000 polychromatic erythrocytes were evaluated, since that was required in the previous OECD guideline (1997). Bone marrow exposure, indicated by a reduced polychromatic to normochromatic erythrocyte ratio, was not confirmed and there was no systemic toxicity observed, but dose levels included limit concentrations specified in the current guideline. In addition, evaluation and acceptance criteria specified in the study report were different from those recommended in the guideline.
Previous evaluation	No, not previously submitted
GLP/Officially recognised testing facilities	Yes
Acceptability/Reliability	Valid
Category study in AIR 5 dossier (L docs)	Category 1

2. Full summary

Executive summary

Disodium N-acetyl-N-(phosphonomethyl)glycine (IN-MCX20, batch: IN-MCX20-002, purity: 63 %) was investigated in a micronucleus test in male and female Crl:CD1 (ICR) mice. Based on the results of a preliminary toxicity study, in which no toxicity was observed up to a limit dose of 2000 mg/kg bw, dose levels for micronucleus tests were selected. Groups of 5 mice per sex per dose level were administered a single dose of 500, 1000 or 2000 mg/kg bw by oral gavage. For the high dose group, 2 additional mice/sex/sampling time point were treated and served as backup (scoring of micronuclei was not performed). Similar constituted groups received the vehicle (Nanopure® water) or the positive control (30 mg/kg bw cyclophosphamide).

Body weights of the animals were collected before dosing, 24 hours after treatment and prior to scheduled necropsy. The animals were observed for clinical signs of toxicity and mortality 1, 3.5 and 24 hours after treatment and prior to scheduled necropsy. About 24 and 48 hours after dosing, the animals of the test item-treated and control groups were sacrificed and bone marrow smears were prepared. For animals of the positive control group, bone marrow was sampled 24 hours after dosing. For each animal, 2000 polychromatic erythrocytes (PCE) were scored for the presence of micronuclei. In addition, the ratio of PCE / normochromatic erythrocytes (NCE) was determined for 1000 erythrocytes.

Treatment with disodium N-acetyl-N-(phosphonomethyl)glycine induced no mortality in the animals and no clinical signs of toxicity were noted at any dose level. In addition, body weight and body weight gain were not affected in any dose group at any sampling time point. Based on the ratio of PCE / NCE, there was no evidence for bone marrow toxicity.

There was no statistically significant and no biologically relevant increase in the frequency of mPCE when compared to vehicle control animals at any dose level and for any sampling time.

Incidences of mPCE in solvent and positive control animals were as expected and fell within the range of the laboratory's historical control data, demonstrating the validity and sensitivity of the test system.

Based on the experimental findings of the present study and under the conditions of the test, disodium N-acetyl-N-(phosphonomethyl)glycine did not induce micronuclei in the bone marrow of male and female mice *in vivo*.

I. MATERIALS AND METHODS

A. MATERIALS

1. Test material:	Disodium N-acetyl-N-(phosphonomethyl)glycine
Identification:	IN-MCX20
Description:	White solid
Lot/Batch #:	IN-MCX20-002
Purity:	63 %
Stability of test compound:	The stability of the test item at storage conditions (under nitrogen in desiccator) was guaranteed until the expiry date 25 Apr 2009. The stability of the test substance in vehicle was confirmed by analytical methods.
Solvent (vehicle) used:	Nanopure® water
2. Control materials	
Solvent (vehicle) control:	Nanopure® water
Positive control:	Cyclophosphamide, 30 mg/kg bw in Nanopure® water
3. Test animals:	
Species:	Mouse
Strain:	Crl:CD1 (ICR)
Sex:	Male and female
Source:	[redacted]
Age at study initiation:	Approx. 7 weeks
Mean weight at dosing:	26.3 – 34.2 (males) and 20.6 – 27.1 (females)
Acclimation period:	At least 5 days
Diet/Food:	LLC Certified Rodent LabDiet® 5002 (PMI® Nutrition International), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually

4. Environmental conditions:

Temperature:	18 - 26 °C
Humidity:	30 - 70 %
Air changes:	Not specified
Photoperiod:	12-hour light and dark cycle

5. Test concentrations and treatment groups:

c) Preliminary toxicity study

Dose levels:	1500 and 2000 mg/kg bw
Concentrations:	Not specified
Dose volume:	Not specified
Number of animals:	3 males/group
Route of administration:	Oral gavage

d) Main micronucleus test

Dose levels:	500, 1000 and 2000 mg/kg bw[37]
Concentrations:	50, 100 and 200 mg/mL
Dose volume:	10 mL/kg bw
Number of animals:	5/ sex/group and additional 2/sex/sampling time point as backup for the high dose group (additional animals were not used for scoring of micronuclei)
Route of administration:	Oral gavage

B. STUDY DESIGN AND METHODS

1. Dates of experimental work: 24 May – 28 Jun 2006
Finalisation date: 28 Aug 2006

2. Animal assignment and treatment:

Preliminary toxicity study:
In a preliminary range-finding test, groups of 3 male mice were administered a single dose of 1500 or 2000 mg/kg bw by oral gavage. The animals were observed for clinical signs of toxicity and mortality immediately after dosing and daily for two days. Based on the results of the preliminary toxicity study, the dose levels for the micronucleus test were selected.

Main micronucleus test:
Groups of 5 mice per sex and dose level were administered a single dose of 500, 1000 or 2000 mg/kg bw. For the high dose group, 2 additional mice/sex/sampling time point were treated and served as backup (scoring of micronuclei was not performed). The test substance was dissolved in Nanopure® water and administered by oral gavage at a constant dosage volume of 10 mL/kg bw. Similar constituted groups of 5 mice/sex received the vehicle (Nanopure® water) or the positive control (30 mg/kg bw cyclophosphamide).
Individual body weights were collected before dosing and 24 and 48 hours after treatment. The animals were observed for clinical signs of toxicity and mortality 1, 3 - 5 and 24 hours after treatment and prior to scheduled necropsy. About 24 and 48 hours after dosing, the animals of the test item-treated and control groups were sacrificed by CO_2 asphyxiation and bone marrow smears were prepared. Animals of the positive control group were sacrificed 24 hours after administration.

3. Slide preparation:

After sacrifice, both femurs of the animals were removed, and marrow was aspirated with the aid of a syringe containing fetal bovine serum (FBS). After centrifugation, the pellet was re-suspended in FBS and a small drop was placed on pre-cleaned microscope slides. Smears were made using a Mini Prep® blood smearing instrument. At least 3 slides were prepared for each animal. The slides were air-dried, fixed in methanol and stained in acridine orange.

[37]: Dosing solutions were adjusted to compensate the purity of the test substance by a correction factor.

4. Slide evaluation:

Slides were coded and evaluated by fluorescent microscopy. For each animal, 2000 polychromatic erythrocytes (PCE) were scored for the presence of micronuclei. Cells containing more than one micronucleus were scored as single micronucleated PCE (mPCE). In addition, the proportion of PCE among 1000 erythrocytes, expressed as PCE / normochromatic erythrocytes (NCE) ratio, was determined.

If no increase in the incidence of mPCE was observed at the 24-hour sampling time point at any dose level, slide evaluation for the 48-hour sampling was performed for animals of the high dose and control group only.

5. Statistics:

Data for the amount of micronucleated polychromatic erythrocytes (mPCE) among 2000 erythrocytes and the ratio of PCE among normochromatic erythrocytes (NCE) were transformed prior to analysis using an arcsine square root or Freeman-Tukey function. Transformed data for PCE and MNPCE frequencies were analyzed separately for normality of distribution and equal variance using the Shapiro-Wilk and Levene's tests, respectively.

For those data that were normally distributed and had equal variance, parametric statistics (e.g. analysis of variace (ANOVA) and Dunnett's test were performed using the transformed data. For those data that were normally distributed but had unequal variance, a robust ANOVA and unequal-variance Dunnett test was done. For those data that were not normally distributed, nonparametric statistics (e.g., Kruskal-Wallis and Dunn's tests) utilizing non-transformed data was performed. The individual animal was considered the experimental unit. All data analyses was one-tailed and conducted at a significance level of 5 %.

6. Acceptance criteria:

The study was considered valid if the following criteria were met:

- In the vehicle control group, the mean frequency of micronucleated polychromatic erythrocytes (mPCE) was within the range of the laboratory's historical control range.
- The positive control induced a statistically significant increase in the frequency of mPCE as compared to the vehicle control group.

7. Evaluation criteria:

The test item was considered positive if the following criteria were met:

- The group mean number of micronucleated polychromatic erythrocytes (mPCE) was statistically significantly increased at one or more concentrations when compared to the concurrent vehicle control value.
- An accompanying statistically significant dose-response increase in mPCE was observed.

The test item was considered negative if the following criteria were met:

- There was no statistically significant, dose-related increase in the group mean mPCE above the concurrent vehicle control at any concentration.
- The mPCE values were within reasonable limits of the recent (past 3 years) laboratory historical control range.

II. RESULTS AND DISCUSSION

A. ANALYTICAL DETERMINATIONS

The dosing formulations were analysed by high performance liquid chromatography (HPLC) and UV/Vis detection. The data indicated that the achieved concentration of test substance in vehicle was ± 14 % of the nominal concentration, which was considered acceptable. In addition, the formulations were shown to be uniformely mixed (Coefficient of variation (CV) = 6, 9 and 3 %) for 50, 100 and 200 mg/mL, respectively. There was no test substance in the 0 mg/mL sample. Stability of the test item in vehicle was confirmed for 5 hours at room temperature.

B. PRELIMINARY TOXICITY STUDY

In the range-finding experiment, no clinical signs of toxicity or mortality were observed.

C. MAIN MICRONUCLEUS TEST

Systemic toxicity:

Mortality:

No mortality occurred.

Clinical signs of toxicity:

There were no clinical signs of toxicity observed at any time point or at any dose level in male or female animals exposed to the test substance.

Body weight and body weight gain:

There were no significant changes in body weight or body weight gain in either male or female animals of any test group.

Evaluation of bone marrow slides:

The ratio of polychromatic (PCE) to normochromatic erythrocytes (NCE) was not affected upon treatment with the test substance at any dose level and sampling time point, indicating that no bone marrow toxicity occurred.

In addition, there was no statistically significant and no biologically relevant increase in the frequency of mPCE when compared to vehicle control animals at any dose level and for any sampling time.

Incidences of mPCE in solvent and positive control animals were as expected and fell within the range of the laboratory's historical control data, demonstrating the validity and sensitivity of the test system.

III. CONCLUSIONS

Based on the results of the present study and under the conditions of the test, disodium N-acetyl-N-(phosphonomethyl)glycine did not induce micronuclei in bone marrow of male and female mice and is therefore considered negative for clastogenicity *in vivo*.

3. Assessment and conclusion

Assessment and conclusion by applicant:

In the present study, disodium N-acetyl-N-(phosphonomethyl)glycine was negative for clastogenic and aneugenic effects in the bone marrow of male and female Crl:CD1 (ICR) mice *in vivo*.
The study was conducted under GLP conditions and in accordance with OECD guideline 474 (1997). Only 2000 polychromatic erythrocytes were evaluated, since that was required in the previous OECD guideline (1997). Bone marrow toxicity, indicated by a reduced polychromatic to normochromatic erythrocyte ratio, or systemic toxicity were not observed. However, the test was performed at limit dose levels in line with the current guideline. The deviations were considered to be of minor degree and to not compromise the validity of the study. The study is therefore considered valid.

Assessment and conclusion by RMS:

CA 5.8.2 Supplementary studies on the active substance

In addition to the studies, which are mandatory to meet current data requirements, several further studies were performed with glyphosate and its salts, respectively.
A 28-day oral immunotoxicity study in female mice was performed according to US EPA OPPTS 870.7800 to assess the immunosupressive potential of glyphosate. Glyphosate did not suppress the humoral component of the immune system when evaluated using an antibody-forming cell (AFC) assay (CA 5.8.2/001) and thus did not show an immuntoxicological potential.
Two mechanistic studies were performed to assess the postulated relationship of alterations of the salivary gland observed in a number of repeated dose toxicity studies and the low pH-value of glyphosate acid-containing preparations. The comparative studies with citric and glyphosate acid on different strains of rats revealed that repeated application of diets at a low pH may result in higher parotid salivary gland weights and histological alterations. The observed findings in salivary glands are attributable to local irritation in the oral cavity and the subsequent adaptive response caused by the administration of glyphosate acid in the diet with a low pH. These adaptive responses can vary in severity between the different strains of rats (CA 5.8.2/002, CA 5.8.2/003), as does the strain-specific time for reversibility of these effects.
Additional pharmacological studies were performed in rats, guinea pigs, mice, and rabbits investigating the potential of glyphosate to affect parameters such as behaviour, haematology, cardiac and circulatory function, respiratory rate, or muscle contractibility *in vivo* and *ex vivo* (CA 5.8.2/004, CA 5.8.2/005, CA 5.8.2/006). Rats were dosed (oral gavage) with glyphosate technical at a dose level of 5000 mg/kg bw; control animals received vehicle only. One-hour post dosing control and treated animals were examined for haematological, electrocardiographic, or behavioural/functional changes. No treatment related effects were observed in treated animals. In addition, *ex vivo* studies on the isolated guinea pig ileum and isolated rat gastrocnemius muscle were performed using a saturated solution of glyphosate (12 mg/mL). This high

concentration of glyphosate caused a contraction of isolated guinea pig ileum, which could be antagonized with atropine indicating a parasympathomimetic activity of glyphosate *ex vivo* at high concentrations. No effect on muscle contraction of the rat gastrocnemius muscle when the sciatic nerve was stimulated was observed when glyphosate was injected (CA 5.8.2/004). The ammonium salt of glyphosate was applied to mice intraperitoneally and rabbits intravenously and clinical signs as well as respiratory parameters and blood pressure were monitored. Glyphosate was not tolerated at a dose level of 5000 mg/kg bw when injected intraperitoneally. Mice receiving a single i.p injection died within 30 min. Anaesthetised rabbits receiving a single intravenous injection of 500 mg/kg bw glyphosate ammonium salt died within a few minutes (unanesthetised rabbits did not die). Surviving animals and animals at lower dose levels of both species exhibited transient symptoms like decreased blood pressure, reduced activity and neuromuscular signs (CA 5.8.2/005). Similarly, the orally administered dose of 5000 mg/kg bw glyphosate, was not tolerated by rats, when the animals were previously anesthetised with chloralose-urethane mixture. Two hours post dosing, a marked decrease in arterial pressure was observed. All animals died within seven hours (CA 5.8.2/006).

Further, the potentiation of toxic effects by glyphosate when co-administered with other substances was investigated. The LD_{50} values of 2-4 D Na salt, isoproturon, or metolachlor decreased when co-administered with 5000 mg/kg bw glyphosate (CA 5.8.2/007). The effect was however, not pronounced.

The acute oral toxicity of glyphosate and the isopropylamine salt of glyphosate was assessed in female goats (CA 5.8.2/008, CA 5.8.2/009). The acute oral LD_{50} of glyphosate was calculated to be 3530 mg/kg bw in goats. Treated animals showed a decreased feed consumption, diarrhoea, and body weight loss (observation period 14 days) (CA 5.8.2/008). The acute oral LD_{50} of an aqueous solution of the isopropylamine salt of glyphosate was calculated to be 5700 mg/kg bw in goats. Considering the content of the glyphosate isopropylamine salt in the aqueous solution, both LD_{50} values are comparable (compare CA 5.8.2/008 and CA 5.8.2/009). Treated animals exhibited reduced feed consumption, diarrhoea, and body weight loss (observation period 14 days). In addition, several goats displayed various neurological signs (CA 5.8.2/009).

The subacute oral toxicity of the isopropylamine salt of glyphosate was investigated in female cattle. Glyphosate isopropylamine salt was administered in doses of 540, 830, 1290, and 2000 mg/kg bw/day on seven consecutive days by stomach tube administration to Brahman cross heifers. All top dose heifers died within 1.5 days after receiving the sixth or seventh dose. Clinical signs of general toxicity included a decrease in feed intake, body weight loss, diarrhoea and behavioural depression including signs of nervous dysfunction, and were noted at the two upper dose levels. Diarrhoea and decreased feed consumption were also seen in the mid dose group receiving 830 mg/kg bw/day (CA 5.8.2/010).

An *ex vivo* study examined the irritating effect of glyphosate isopropylamine salt in comparison with its product formulation or ingredients of the formulation on gastrointestinal mucosa of anesthetized dogs. Direct application of Roundup® herbicide, or surfactant caused mild mucosal damage in the stomach and intestine. These effects were more severe with the Roundup® formulation than with either the isopropylamine salt of glyphosate or the surfactant alone. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid (CA 5.8.2/011).

Acute toxicity of glyphosate was also studied after intraperitoneal injection in rats (CA 5.8.2/012, CA 5.8.2/013). The acute intraperitoneal LD_{50} was calculated to be 919 mg/kg bw in female rats (CA 5.8.2/012) and 281 mg/kg bw and 467 mg/kg bw in male and female rats, respectively (CA 5.8.2/013). Based on these results, the acute toxicity of glyphosate was higher by intraperitoneal injection as compared to oral, dermal or inhalation exposure.

In the study from [redacted] (2012, CA 5.8.2/014), the *in vitro* percutaneous absorption of glyphosate acid through abraded rabbit skin was assessed following a 6-hour exposure period and a subsequent 18 hour monitoring period. The results of this *in vitro* study indicate the dermal absorption of glyphosate through abraded rabbit skin is slow. The vast majority of glyphosate will be washed off during normal washing procedures. The mean total amount absorbed after 24 hours was 2.42 % of the applied dose. The reported total potentially absorbable amount, represented by the mean absorbed dose together with the mean amount in the remaining dermis was 2.66 % of the applied dose.

A literature search for the active substance glyphosate resulted in two publications considered relevant and reliable for reporting. The publications are summariaed in the summary table presented above the first

publication in the respective summary section below.
Glyphosate was investigated for its potential to interfere with cellular function *in vitro* (CA 5.8.2/014, CA 5.8.2/015). Glyphosate was shown to reduce liver and cardiac organoid integrity and viability at doses from 250 µM to 2500 µM. When cardiac organoids were exposed to glyphosate a reduction of the beating rate was found (CA 5.8.2/014).
The transcriptome and metabolome profile of differentiated HepaRG cells was examined after exposure to 0.06, 6, and 600 µM glyphosate. Glyphosate was found to be only weakly toxic, inducing little change in transcriptome profiles when compared to other concurrent test substances. Metabolomics analysis of HepaRG cells exposed to glyphosate revealed a significant decrease in long chain fatty acid- and polyunsaturated fatty acid-levels (CA 5.8.2/015).

Table 5.8.2-1: Other/special studies on toxicological properties of glyphosate

Annex point	Study	Study type	Substance(s)	Reference list- related category§	Result
CA 5.8.2/001	[redacted] 2012	*in vivo:* 28-Day Oral (Dietary) Immunotoxicity Study in Female B6C3F1 Mice	Glyphosate (Batch: GLP-0807-19475-T, Purity: 85.2 % by weight including water, 95.11 % dried)	Valid, Category 2a	Treatment with glyphosate did not suppress the humoral component of the immune system when evaluated using the splenic antibody-forming cell (AFC) assay.
CA 5.8.2/002	[redacted] 2010	*in vivo:* Eight-week oral (diet and gavage) toxicity study of citric acid in male Crl:CD® (Sprague Dawley) rats	Citric acid, anhydrous (Batch: XR3050, Purity: 99.9 %)	Valid, Category 2a	Rats, dosed with acidic diet or acidic fluid, exhibited higher parotid salivary gland weights when compared to pH neutral, basal diet fed control animals. Histologic effects consisted of cytoplasmic alterations in the parotid salivary glands characterized by the presence of hypertrophied acinar cells with basophilic granular cytoplasm. The observed effects are considered adaptive responses to local irritation of the low pH diet in the oral cavity rather than adverse effects.
CA 5.8.2/003	[redacted] 1996	*in vivo:* 28-Day Oral (Dietary) Study. Comparison of salivary gland effects in male Alpk:AP_fSD (Wistar-derived) [AP], Sprague Dawley (Charles River CD) [CD], and Fischer 344 [F344] rats	Glyphosate acid (Batch: P24, Purity: 95.6 %)	Valid, Category 2a	Administration of diets containing 20000 ppm glyphosate acid to rats produced marked strain differences in the severity of effect in the parotid salivary gland. Microscopic examination showed the most pronounced effect occurred in the F344 strain (diffuse cytoplasmic basophilia and enlargement of the parotid acinar cells). Similar but slight effects

Table 5.8.2-1: Other/special studies on toxicological properties of glyphosate

Annex point	Study	Study type	Substance(s)	Reference list- related category§	Result
					involving small foci of cells occurred in the AP and CD strains. Complete recovery of salivary gland effects was apparent in AP and CD strains following a 4-week post-exposure period; significant, but not complete, recovery was evident in the F344 strain.
CA 5.8.2/004	[redacted] 1996	*in vivo:* Pharmacology screening study in male and female Sprague Dawley (Charles River CD) rats *ex vivo*: Pharmacology screening study on isolated guinea pig ileum (male Dunkin Hartley Albino guinea pigs) and isolated rat gastrocnemius muscle	Glyphosate technical (Batch: H95D161A, Purity: 95.3 %)	Valid, Category 2a	*in vivo:* Following oral gavage (5000 mg/kg bw), haematological parameters, electrocardiograms, and nervous system parameters (open field observations, response to various stimuli) were investigated. There were no differences in response between treated and control animals. *ex vivo*: Glyphosate caused a contractile response to isolated guinea pig ileum similar to that seen with acetylcholine.
CA 5.8.2/005	[redacted] 1992	*in vivo:* General pharmacological study (7 days) in male and female ICR mice (single i.p. injection) and male albino rabbits (single i.v. injection)	Glyphosate, ammonium salt (MON-8750) (Batch: RUD-9201-3544F, Purity: 94.78 %)	Supportive, Category 2a	Mice were treated with 0, 78.1, 313, 1250, and 5000 mg/kg bw glyphosate. All animals dosed with 5000 mg/kg bw died. Mice dosed with 1250 mg/kg bw exhibited clinical signs of toxicity affecting awareness, motor activity, central nervous system excitation, posture, motor incoordination, muscle tone, reflexes, and autonomic signs. In addition, decreased blood pressure was observed. Mice receiving doses ≤313 mg/kg bw exhibited no clinical signs of toxicity. Rabbits were dosed with 0, 7.81, 31.3, 125, and 500 mg/kg bw glyphosate. Half of the rabbits were clinically observed. The other half was used for digital monitoring of respiratory and circulatory parameters under urethane-anaesthesia. Animals dosed with 500 mg/kg

Table 5.8.2-1: Other/special studies on toxicological properties of glyphosate

Annex point	Study	Study type	Substance(s)	Reference list- related category§	Result
					bw without anaesthesia showed decreased spontaneous activity and increased respiratory rate. Animals dosed with 500 mg/kg bw under anaesthesia died within a few minutes after injection. These animals exhibited decreased heart rate, blood pressure and respiratory rate, and voltage of QRS complex in electrocardiogram. Rabbits dosed with 125 or 31.3 mg/kg bw exhibited transient symptoms like decreased blood pressure, reduced activity and neuromuscular signs. Animals dosed with 7.81 mg/kg bw exhibited no clinical signs of toxicity.
CA 5.8.2/006	[redacted], 1988	*in vivo*: Toxicodynamic study, oral, in male S/Wistar rats	Glyphosate, technical (Batch: 72390788, Purity: 96 %)	Supportive, Category 3a	Toxicodynamics were examined by the measurement of heart rate, ECG, and venous- and arterial blood pressure. At 5000 mg/kg bw glyphosate the animals narcotised with chloralose-urethane mixture died within 2 to 7 hours. After treatment, decreased pulse, respiratory rate, and arterial pressure were measured. ECG-II and venous pressure changes were incidental and insignificant. White spots were seen in the edges of livers of the dead animals.
CA 5.8.2/007	[redacted] 1988	*in vivo:* Single oral administration of glyphosate in combination with either 2-4 D Na salt, isoproturon, or metolachlor to male Wistar rats	Glyphosate, technical (Batch: not specified, Purity: not specified)	Supportive, Category 2a	LD_{50} values of 2-4 D Na salt, isoproturon and metolachlor were slightly lower when co-administered with glyphosate at 5000 mg/kg bw.
CA 5.8.2/008	[redacted], 1987	*in vivo:* Acute oral toxicity (gavage), female Spanish goat	Glyphosate (Batch: XHJ-64, NBP1494248, Purity: 98.7 %)	Supportive, Category 2a	LD_{50} = 3530 mg/kg bw
CA 5.8.2/009	[redacted], 1987	*in vivo:* Acute oral toxicity (gavage), female Spanish goat	Glyphosate, isopropylamine salt (MON-0139) (Batch: LURT 08020, Purity: 62.5 %)	Supportive, Category 2a	LD_{50} = 5700 mg/kg bw

Table 5.8.2-1: Other/special studies on toxicological properties of glyphosate

Annex point	Study	Study type	Substance(s)	Reference list- related category§	Result
CA 5.8.2/010	[redacted] 1987	*in vivo:* Subacute toxicity, oral (gavage) exposure for seven days, in female cattle (Braham cross heifers)	Glyphosate, isopropylamine salt (MON-0139) (Batch: LBRT 08023, Purity: 62.4 %)	Supportive, Category 2a	Animals received doses of 540, 830, 1290, or 2000 mg/kg bw/day. Clinical signs of toxicity occurred at doses ≥830 mg/kg bw/day, including loss of appetite and diarrhoea. Mortality occurred at doses of ≥1290 mg/kg bw/day. Nervous system effects (head tremors, convulsions, ataxia, etc.) were observed at 2000 mg/kg bw/day prior to death.
CA 5.8.2/011	[redacted] 1987	*in vivo/ex vivo:* Irritating effect of glyphosate, surfactant, and roundup on exposed stomach and small intestine mucosa in anesthetized Beagle dogs	- Glyphosate, isopropylamine salt (MON139) (Batch: LIRT09023, Purity: 63.2 %) - Surfactant (MON-0818) (Batch: not specified, Purity: not specified) - Roundup (Batch: Oda B6E20 88.10, Purity/ Composition: 41 % isopropylamine salt of glyphosate, 15 % surfactant, water) - Hydrochloric acid, 6 N; diluted to 0.25 N with water	Supportive, Category 2a	Direct application of Roundup® herbicide, or surfactant caused mild mucosal damage in the stomach and intestine. These effects were more severe with the Roundup formulation than with either the IPA salt of glyphosate or the surfactant alone. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid.
CA 5.8.2/012	[redacted] 1980	*in vivo:* Acute intraperitoneal toxicity, female Wistar rat	Glyphosate (Batch: not specified, Purity: not specified)	Supportive, Category 4a	LD_{50} = 919 mg/kg bw

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	2012
Report title	Glyphosate – A 28-Day Oral (Dietary) Immunotoxicity Study in Female B6C3F1 Mice
Report No	[redacted]-50393
Document No	M-651162-01-1
Guidelines followed in study	US EPA OPPTS 870.7800 (1998)
Deviations from current test guideline (No equivalent EU or OECD Test Guideline. US EPA specific guideline developed under FIFRA)	The study was performed according to EPA OPPTS 870.7800 to meet and evaluate US EPA specific endpoint for immunotoxicity under the Federal Insecticide, Fungicide, and Rodenticide Act. No equivalent OECD study guideline exists.
Previous evaluation	Yes, accepted in RAR (2015).
GLP/Officially recognised testing facilities	Yes, conducted under GLP
Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

The potential immunotoxicity of glyphosate was evaluated after repeated dietary administration to B6C3F1 mice. Four groups of 10 female mice were offered diets containing glyphosate concentrations of 0, 500, 1500 or 5000 ppm (equivalent to 0, 150, 449, and 1448 mg/kg bw/day) and for 28 consecutive days. A further group of 10 females were used as positive immunosuppressive control group. These mice received basal diet for 28 days and were treated with an intraperitoneal (i.p.) injection of 50 mg/kg bw/day cyclophosphamide monohydrate (CPS) once daily for four consecutive days (study days 24 - 27).
The animals were checked twice daily for mortality and moribundity, and once daily for clinical signs. Detailed clinical examinations were performed once per week. Body weights were recorded twice weekly. Food consumption was recorded in weekly intervals, and food intake was calculated for the corresponding body weight intervals. Blood samples for IgM antibody analysis were collected from all mice at scheduled necropsy. At termination, the animals were sacrificed and subjected to a full macroscopic post-mortem examination. Spleens and thymus were weighed and specified tissues preserved.
There were no test substance-related effects on survival, clinical observations, body weight, food consumption, as well as any gross pathological changes. There were no test substance-related effects on spleen or thymus weights (absolute or relative to final body weight), spleen cellularity, or the T-cell dependent antibody response (TDAR), as measured by the splenic antibody-forming cell (AFC) IgM Specific Activity (AFC/10^6 spleen cells) and Total Spleen Activity (AFC/spleen), at any dosage level tested.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:

Identification:	Glyphosate
Description:	White powder
Lot/Batch #:	GLP-0807-19475-T
Purity:	95.11 % (dried)
Stability of test compound:	Expiry date: 2011-06-10
Vehicle and/ or positive control:	Basal diet Cyclophosphamide monohydrate
Test animals:	
Species:	Mouse
Strain:	B6C3F1/Crl
Source:	[redacted]
Age:	Approx. 37 days (on arrival)
Sex:	Female
Weight at dosing:	16.5 – 20.0 g
Acclimation period:	14 days
Diet/Food:	Certified Rodent LabDiet® # 5002 (meal) (PMI Nutrition International, LCC.), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Individually in stainless steel, wire-mesh cages suspended above cage-board.
Environmental conditions:	Temperature: 22 ± 3 °C Humidity: 50 ± 20 % Air changes: 10/hour Photocycle: 12 hours light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 2010-10-05 to 2010-11-16

Animal assignment and treatment

In a 28-day oral immunotoxicity study groups of 10 female B6C3F1/Crl mice received daily dietary doses of 0, 500, 1500 and 5000 ppm glyphosate (equivalent to 0, 150, 449 and 1448 mg/kg bw/day).

A further group of 10 females were used as positive immunosuppressive control group. These mice received basal diet for 28 days and were treated with an intraperitoneal (IP) injection of 50 mg/kg bw/day CPS once daily for four consecutive days (study days 24 - 27).

Test diets were prepared weekly and stored at room temperature. For the vehicle and positive control groups an appropriate amount of basal diet was weighed into a plastic storage bag. For the test substance groups 500 g of basal diet was weighed (pre-mixture). An appropriate amount of glyphosate was weighted into a mortar, mixed with a small amount of the pre-mixture basal diet, and ground until uniform. This admixture was transferred to a Hobart mixer and mixed with the remainder of the pre-mixture basal diet for five minutes. The resultant mixture was then transferred to a V-blender with a sufficient amount of basal diet to achieve the correct diet concentration and mixed for an additional 10 minutes using an intensifier bar during the first and last three minutes of mixing to ensure a homogeneous mixture. The test diets were prepared from the lowest to highest concentration. The stability and homogeneity of the test substance in the diet was determined in an in-house stability study at 450 and 5500 ppm. Analyses for achieved concentrations

on the test diets were done during study weeks 0 and 3.

Mortality
Each animal was checked for mortality or signs of morbidity twice a day during the treatment period.

Clinical observations
A check for clinical signs of toxicity was made once daily on all animals. In addition, a detailed clinical examination was performed once a week during the study period, beginning one week prior to randomisation, and on the day of scheduled necropsy.

Body weight
Individual body weights were recorded twice weekly, beginning approximately one week prior to randomization, at the time of animal selection for randomization, on study day 0, and just prior to the scheduled necropsy. Mean body weights and mean body weight changes were calculated for the corresponding intervals.

Food consumption and test substance intake
The quantity of food consumed was recorded for each animal weekly, beginning approximately one week prior to randomization, and just prior to the scheduled necropsy. Food intake was calculated as g/animal/day for the corresponding body weight intervals. The mean amounts of glyphosate consumed (mg/kg bw/day) per dose group were calculated from the mean food consumed (g/kg of body weight/day) and the appropriate target concentration of glyphosate in the food (mg/kg of diet).

Serum collection for possible IgM antibody analysis
All animals were immunised with an intravenous injection of sRBC on study day 24. For determination of the possible extent of the suppression of IgM antibody production blood samples were collected from all animals at scheduled necropsy and processed to serum. Following euthanasia by carbon dioxide inhalation, approximately 0.75 mL of blood was collected from the inferior vena cava of each mouse into a tube containing no anticoagulant and allowed to clot. Serum was obtained and aliquots of approximately 150 µL (including any remainder serum) were transferred to cryovials and stored frozen (approximately -70 °C).

Sacrifice and pathology
A complete necropsy was conducted on all animals at scheduled termination or on animals that died or were sacrificed during the study period. Any macroscopic findings were recorded. The following organ weights were determined from all animals surviving to scheduled termination: spleen and thymus. The ratio of organ weights to final body weights were calculated.
Tissue samples were taken from the spleen and thymus. Spleen samples were placed in EBSS/HEPES buffer. Thymus samples were preserved in 10 % neutral-buffered formalin.

Spleen processing for immunotoxicological evaluation
For the determination of the number of specific IgM antibody-forming cells directed towards sRBC an AFC assay, as a modification of the Jerne plaque assay (Jerne *et al.*, 1963, 1974) was conducted.

Spleens were collected from all animals at the scheduled necropsy (study day 28) immediately following blood collection. Individual spleens were placed into individual tared tubes containing EBSS with 15 mM HEPES, supplemented with gentamicin as a bacteriostat, and maintained on ice. Each tube was then weighed to provide a "wet" weight for each spleen. Spleen samples from Groups 1 - 4 animals were randomized and coded for antibody-forming cell (AFC) analysis. Spleen samples from Group 5 were labelled as positive control samples for analysis. The spleen samples were placed on crushed ice until procession for AFC analysis.
The spleen samples were processed into single-cell suspensions. The cell suspensions were then centrifuged and resuspended in EBSS with HEPES. Spleen cell counts were performed using a Model Z1™ Coulter Counter®. Viability of splenocytes was determined using propidium iodide and the Coulter® EPICS® XL-MCL™ Flow Cytometer.

Statistics
Body weight, body weight change, and food consumption data were subjected to a parametric one-way ANOVA (Snedecor and Cochran, 1980) to determine intergroup differences. If the ANOVA revealed statistically significant ($p<0.05$) intergroup variance, Dunnett's test (Dunnett, 1955, 1964) was used to compare the test substance treated groups to the control group.
The positive control data were evaluated using the Student's t-Test (Sokal and Rohlf, 1981) and compared to the basal diet control group.

Organ weight (wet spleen and thymus), final body weight, and AFC data obtained were first tested for homogeneity of variances using the Bartlett's Chi Square test (Bartlett, 1937). Homogeneous data were evaluated using a parametric one-way ANOVA (Kruskal and Wallis, 1952). When significant differences occurred, the treatment groups were compared to the basal diet control group using Dunnett's test (Dunnett, 1955, 1964). Non-homogeneous data were evaluated using a non-parametric ANOVA (Wilson, 1956). When significant differences occurred, the treatment groups were compared to the basal diet control group using the Gehan-Wilcoxon test when appropriate (Gross & Clark, 1975). The Jonckheere's test (Hollander & Wolfe, 1973) was used to test for dose-related trends across the basal diet control and test substance treated groups. The positive control data were evaluated using the Student's t Test (Sokal & Rohlf, 1981) and compared to the basal diet control group. The criteria for accepting the results of the positive control group included a statistically significant ($p\leq0.05$) decrease in the response when compared to the response of the basal diet control group.
The AFC data were expressed as Specific Activity, IgM antibody forming cells per million spleen cells (AFC/106 spleen cells), and as IgM Total Spleen Activity (AFC/spleen).

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The achieved concentrations of glyphosate in the dietary preparation were in the range of 85.6 – 97.5 % of nominal, and therefore within the acceptable range of 85 – 115 %. The diet formulations were homogeneous and stable for 10 days when stored at room temperature with the following exception. During homogeneity/concentration acceptability testing, the 450 ppm diet formulation was 83.1 % of target. The 5500-ppm diet formulation was within acceptable range (90.8 %) but was considered low, therefore, calibration standards were prepared as matrix-based samples and a cross-validation was conducted. The diet formulations were reanalysed using matrix-based calibration standards and met the testing facilities SOP acceptance criteria for homogeneity and concentration acceptability. Based on these results, the protocol-specified doses of test substance were offered to the animals. The test substance was not detected in the basal diet that was offered to the basal diet control (Group 1) and positive control (Group 5) groups.

B. MORTALITY AND CLINICAL SIGNS
There were no mortalities observed during the study period.

C. CLINICAL OBSERVATIONS
There were no test substance-related clinical findings.

D. BODY WEIGHT
There were no test substance related effects on body weights in any of the dose groups.

E. FOOD CONSUMPTION AND COMPOUND INTAKE
There were no test substance-related effects on food consumption noted.

The group mean achieved doses are summarised below.

Table 5.8.2-2: Glyphosate – A 28-Day Oral (Dietary) Immunotoxicity Study in Female B6C3F1 Mice ([redacted] 2012): Group mean achieved dose levels of glyphosate

Dose group	Dietary concentration (ppm)	Mean achieved dose level (mg/kg bw/day)
1 (vehicle control)*	0	0
2 (low)	500	150.1
3 (mid)	1500	449.1
4 (high)	5000	1447.5
5 (positive control)	50 mg/kg CPS**	0

* basal diet group
** CPS = cyclophosphamide

F. NECROPSY

Gross pathology

There were no test substance-related macroscopic effects.

Treatment with the positive control CPS produced a small thymus in three of the 10 animals. These changes were consistent with the known effects of CPS in female B6C3F1 mice.

Organ weights

There were no test substance-related effects on terminal body weights or on spleen or thymus weights (absolute or relative to final body weight) when the test substance-treated groups were compared to the basal diet control group.

Treatment with the positive control CPS produced statistically significantly lower spleen and thymus weights (absolute and relative to final body weight) when compared to the basal diet control group. These changes were consistent with the known effects of CPS in female B6C3F1 mice.

The results of final body and organ weight determinations are presented in the table below.

Table 5.8.2-3: Glyphosate – A 28-Day Oral (Dietary) Immunotoxicity Study in Female B6C3F1 Mice ([redacted] 2012): Final body weight and organ weight data

Dose group	Body weight (g)[#]	Spleen weight		Thymus	
		Absolut	Relative	Absolut	Relative
		(mg) [#]	(% of body weight) [#]	(mg) [#]	(% of body weight) [#]
1 (vehicle control)*	20.9 ± 0.3	85.3 ± 3.5	0.41 ± 0.02	44.3 ± 3.5	0.21 ± 0.02

G. AFC ASSAY RESULTS

There were no test substance-related effects on spleen cell numbers, and in the functional evaluation of the IgM antibody-forming cell (AFC) response, treatment with glyphosate did not result in a statistically significant suppression of the humoral immune response when evaluated as either Specific Activity (AFC/106 spleen cells) or Total Spleen Activity (AFC/spleen). There were no statistically significant differences nor any dose-related trends noted when the basal diet control and test substance-treated groups were compared.

Statistically significantly lower spleen cell numbers, mean specific activity, and mean total spleen activity values were noted in the positive control (CPS treated) group when compared to the basal diet control group. These effects were consistent with the known immunosuppressant effects of CPS and validated the appropriateness of the AFC assay.
The results of the AFC assay are summarised in the table below.

Table 5.8.2-4: Glyphosate – A 28-Day Oral (Dietary) Immunotoxicity Study in Female B6C3F1 Mice ([redacted] 2012): Results of AFC assay

Dose group	Spleen cells (x 10^7)#	IgM AFC / 10^6 spleen cells#	IgM AFC/spleen (x 10^3)#
1 (vehicle control)*	11.29 ± 0.65	1160 ± 131	127 ± 11
2 (low)	11.45 ± 0.64	1273 ± 123	144 ± 16
3 (mid)	13.45 ± 1.24	1368 ± 163	190 ± 37
4 (high)	12.51 ± 0.66	1514 ± 204	195 ± 32

** Statistically significant from vehicle control at p ≤0.01

Study conclusion
Repeated dietary administration of glyphosate to females B6C3F1 mice did not suppress the humoral component of the immune system. The no-observed-effect level (NOEL) for suppression of the humoral immune response in female B6C3F1 mice offered glyphosate in the diet for 28 days was considered to be 5000 ppm (equivalent to 1448 mg/kg bw/day), the highest dietary concentration.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Treatment of female B6C3F1 mice for 28 days with glyphosate did not suppress the humoral component of the immune system when evaluated using the AFC assay. The no-observed-effect level (NOEL) was considered to be 5000 ppm (equivalent to 1448 mg/kg of body weight/day) in female mice, the highest dietary concentration. The study was performed according to EPA OPPTS 870.7800 and no deviations were apparent. The study is considered informative and acceptable.

Assessment and conclusion by RMS:

2. Full summary

A number of repeat dose studies in rodents with glyphosate technical acid have identified alterations of the salivary glands, described as increased basophilic staining and enlargement of cytoplasm, especially in the parotid salivary glands. The toxicological significance of these observations were considered not relevant, by some reviewers and unknown by others. In the 2004 JMPR review of glyphosate, a hypothesis was proposed that the low pH of glyphosate technical acid in the diet caused local irritation in the oral cavity leading to the observed salivary gland effects. The objective of this study was to evaluate the potential effects of low pH diet on the parotid salivary glands. Citric acid was selected as an appropriate surrogate for glyphosate, having both a similar pH-dilution curve and low toxicity. Citric acid was presented in the diet (14000 ppm) and compared with a typical pH basal diet control group. A higher pH diet group fed basal diet with trisodium citrate dihydrate (21400 ppm, an equivalent citrate ion concentration to the citric acid group) was also compared with the typical pH basal diet control group. In addition, low pH aqueous citric acid was administered by gavage and compared to a control deionised water gavage group to evaluate potential systemic effects of the citrate ion on the parotid salivary glands. These five test groups, each consisting of 10 male rats, were dosed for eight weeks (minimum of 56 days).
Clinical signs, bodyweight and food consumption were monitored during the study. All animals were subjected to a gross necropsy examination and a comprehensive histopathological evaluation of tissues was performed. The findings are summarised as follows:
There were no test substance-related clinical signs of toxicity, as well as no test substance-related effects on body weight, and food consumption.

Test substance-related effects on organ weights consisted of statistically significantly higher parotid salivary gland weights in the low pH diet group only (citric acid) when compared to the respective control group. Non-statistically significantly higher parotid salivary gland weights were noted in the gavage citric acid and high pH dietary (trisodium citrate dihydrate) groups when compared to their respective control group. There were no statistically significant test substance-related effects on the fused mandibular/sublingual salivary gland weights when the respective control and test substance-treated groups were compared; however, a non-statistically significantly higher fused mandibular/sublingual salivary gland weight was noted in the low pH diet group (14000 ppm citric acid).

Histological effects consisted of cytoplasmic alterations in the parotid salivary glands characterized by the presence of hypertrophied acinar cells with basophilic granular cytoplasm. Although the overall incidence of affected animals was similar in all control and citric acid or trisodium citrate dihydrate-treated groups, these effects were clearly most severe in the low pH diet group (14000 ppm citric acid in basal diet). With

the absence of microscopic findings such as cytotoxicity and hyperplasia, the observed effects are considered to be an adaptive response to local irritation of the low pH diet in the oral cavity rather than an adverse effect.

Citric acid administered orally via gavage or diet and trisodium citrate dihydrate administered via the diet to Sprague Dawley rats for 56 days resulted in higher parotid salivary gland weights and a generally correlative increase in severity of background cytoplasmic alterations in the parotid salivary glands in all dose groups (gavage citric acid, diet citric acid, and diet trisodium citrate dihydrate). The magnitude of change in parotid gland weight and severity of the cytoplasmic alteration in the parotid salivary glands was most severe in the low pH diet citric acid group.

I. MATERIALS AND METHODS

A. MATERIALS

Test materials:

Identification:	Anhydrous Citric Acid
Description:	White powder
Lot/Batch #:	XR3050
Purity:	99.9 %
Stability of test compound:	Stable at room temperature until 2010-01-06
Identification:	Trisodium Citrate Dihydrate (TCD)
Description:	White crystalline solid
Lot/Batch #:	1387609
Purity:	99.3 %
Stability of test compound:	Stable at room temperature until 2011-03-01
Vehicle and/ or positive control:	Gavage: deionised water, Diet: plain diet
Test animals:	
Species:	Rats
Strain:	Sprague-Dawley (CD)
Source:	[redacted]
Age:	Approx. 6 weeks upon beginning of treatment
Sex:	Males
Weight at dosing:	177 - 227 g
Acclimation period:	14 days
Diet/Food:	Certified Rodent LabDiet #5002 (PMI Nutrition International, LLC), *ad libitum* except for fasting period prior to necropsy
Water:	Tap water, *ad libitum*
Housing:	Upon arrival, animals were housed three per cage for approximately 3 days. Thereafter, all animals were housed individually in clean, stainless steel, wire-mesh cages suspended above cage-board.
Environmental conditions:	Temperature: 22 ± 3 °C Humidity: 50 ± 20 % Air changes: at least 10/hour Photocycle: 12 hours light/dark cycle

B. STUDY DESIGN AND METHODS

In life dates: 2009-02-10 to 2009-04-21

Animal assignment and treatment
In an 8 week gavage and feeding study groups of 10 male Sprague Dawley rats received the respective vehicles or test substances for 56 consecutive days via oral gavage (Groups 1 and 3) or in the diet (Groups 2, 4 and 5; see table below). A low pH diet containing 14000 ppm of citric acid in basal diet was offered continuously to Group 4. A high pH diet containing 21400 ppm of trisodium citrate dihydrate in basal diet (at an equivalent citrate ion concentration to Group 4) was offered continuously to Group 5. A concurrent control group (Group 2) received the basal diet on a comparable regimen. Citric acid in the vehicle, deionised water, was administered orally by gavage at a dose level of 791-1316 mg/kg bw/day to Group 3. Concentrations of the Group 3 formulations were calculated and adjusted weekly, based on the average food consumption and body weights of the Group 4 animals from the previous week of dosing in order to maintain approximately equivalent citric acid dose levels to Group 4. A concurrent gavage control group (Group 1) received the vehicle on a comparable regimen.

Table 5.8.2-5: An 8-Week Oral (Diet and Gavage) Toxicity Study of Citric Acid in Male Rats ([redacted] 2010): Study group assignment

Group number	Test substance application	Dose level (mg/kg bw/day or ppm)	Dose volume (mL/kg)	Number of animals
1	Gavage Vehicle	0	10	10
2	Basal Diet	0	na	10
3	Gavage Citric Acid (low pH)	791-1316	10	10
4	Diet Citric Acid (low pH)	14000*	na	10
5	Diet Trisodium Citrate (high pH)	21400*	na	10

na - not applicable, * stoichiometrically equivalent for citrate ion concentration

Observations
All animals were observed twice daily for mortality and moribundity. Clinical examinations were performed daily, and detailed physical examinations were performed weekly.

Body weight
Individual body weights were recorded weekly.

Food consumption and compound intake
Food consumption was recorded weekly.

Sacrifice and pathology
All animals sacrificed at scheduled termination were subjected to a gross pathological examination. Any macroscopic findings were recorded.
The following organ weights were determined: parotid salivary glands, mandibular salivary glands and sublingual salivary glands. The mandibular and sublingual salivary glands were weighed together as one organ since they were fused and could not be adequately separated for weighing.
Tissue samples were taken from the following organs and preserved in buffered formalin: adrenals, aorta, bone & bone marrow (sternum and femur (incl. joint)), brain (cerebrum at two levels; cerebellum with medulla/pons), caecum, colon, duodenum, epididymides, eyes with optic nerves, gross lesions, harderian glands, heart, ileum, jejunum, kidneys, lacrimal gland (exorbital), liver, lungs (incl. bronchi), mammary gland, lymph nodes (mandibular, mesenteric and axillary), nasal cavity, oesophagus, pancreas, Peyer's patches, pituitary, prostrate, rectum, salivary glands (mandibular, parotid, sublingual), sciatic nerve, seminal vesicles, skeletal muscle, skin, spinal cord (cervical, thoracic, lumbar), spleen, stomach, testes,

thymus, thyroid/parathyroid, tongue, trachea and urinary bladder.
Microscopic examination was performed on the parotid salivary glands and gross lesions from all animals at the scheduled necropsy.

Statistics
All statistical tests were performed using the [redacted] Toxicology Data Management System (WTDMS™). Analyses were conducted using two-tailed tests (except as noted otherwise) for minimum significance levels of 1 % and 5 %, comparing each test substance-treated group to its respective control group.
Body weight, body weight change, food consumption, and organ weight data were subjected to a parametric one-way analysis of variance (ANOVA) to determine intergroup differences. If the ANOVA identified statistically significant ($p<0.05$) intergroup variance, Dunnett's test was used to compare each of the test substance-treated groups to the respective control group (Group 1 to Group 3 and Group 2 to Groups 4 and 5). Group 1 was also compared to Group 2.
Statistical analysis of the severity of histological changes was conducted. Individual animals were assigned severity scores based on parotid salivary gland changes (0=without histological change, 1=minimal change, 2=mild change, and 3=moderate change). The severity scores were then compared statistically using the Mann-Whitney U-test by comparing Group 1 to Group 3 and Group 2 to Groups 4 and 5.

II. RESULTS AND DISCUSSION

A. MORTALITY
No deaths occurred during the study.

B. CLINICAL OBSERVATIONS
All clinical findings in the test substance-treated groups were noted with similar incidence in the control groups, were limited to single animals, and/or were common findings for laboratory rats of this age and strain.

C. BODY WEIGHT
There were no statistically significant differences when the respective control and test substance-treated groups were compared.

D. FOOD AND TEST SUBSTANCE CONSUMPTION
Food consumption was unaffected by citric acid or trisodium citrate dihydrate administration. A statistically significant decrease in food consumption of the gavage citric acid group (Group 3, Week 7/8) was probably due to biological variability and not considered related to test substance administration.

E. PATHOLOGY
Organ weights
Test substance-related effects on organ weights consisted of statistically significant higher absolute and relative parotid salivary gland weights in the low pH diet group (14000 ppm citric acid) when compared to the dietary control group; the magnitude of change was >40 % (see table below).
Higher absolute and relative parotid salivary gland weights were also observed in the low pH gavage group (791-1316 mg/kg bw/day citric acid) and in the high pH diet group (21400 ppm TCD) when compared to their respective control groups. However, the parotid salivary gland weight differences in the low pH gavage and high pH diet groups were not statistically significant and were of much lesser magnitude of change.
There were no other statistically significant test substance-related effects on the fused mandibular/ sublingual or parotid salivary gland weights when the control groups and test substance-treated groups were compared.

Table 5.8.2-6: An 8-Week Oral (Diet and Gavage) Toxicity Study of Citric Acid in Male Rats ([redacted] 2010): Mean absolute and relative organ weights (mean ± SD)

	Gavage administration		Dietary administration		
	Aqueous control	**791-1316 mg/kg bw/day citric acid**	**Basal diet control**	**Low pH diet, 14000 ppm citric acid**	**High pH diet, 21400 ppm trisodium citrate dihydrate**
Absolute mandibular / sublingual fused glands weight (g)	0.7625 ± 0.05446	0.7873 ± 0.08397	0.7682 ± 0.08670	0.8872 ± 0.16548	0.7869 ± 0.07028
Relative mandibular / sublingual fused glands weight (g/100 g bw)	0.179 ± 0.0105	0.180 ± 0.0178	0.173 ± 0.0221	0.199 ± 0.0339	0.183 ± 0.0201
Absolute parotid gland weight (g)	0.3500 ± 0.12450	0.4082 ± 0.11990	0.2758 ± 0.08514	0.3905* ± 0.10920	0.3502 ± 0.08986
Relative parotid gland weight (g/100 g bw)	0.083 ± 0.0299	0.095 0.0304	0.062 ± 0.0194	0.088* ± 0.0236	0.082 0.0220

* statistically significantly different from relevant control group ($p<0.05$) using Dunnett's test

Necropsy
All macroscopic findings noted were considered spontaneous and/or incidental in nature and unrelated to test substance administration.

Histopathology
Test substance-related histological effects consisted of a higher severity of cytoplasmic alterations in the parotid salivary glands of the citric acid and trisodium citrate dihydrate-treated groups when compared to their respective control groups (see table below). The severity of cytoplasmic alteration was increased in all dose groups; however, the cytoplasmic alteration was clearly most severe in the low pH diet group (Group 4; 14000 ppm citric acid). Furthermore, statistical significance for the grade of severity was only achieved in the low pH diet group, while the severity in the other dose groups was not statistically significantly different from the respective control group.
Cytoplasmic alteration in the parotid salivary glands was characterized by the presence of hypertrophied acinar cells with basophilic granular cytoplasm. The severity grades varied from minimal to moderate, displayed by increasing numbers of affected acinar cells and more pronounced hypertrophy of acinar cells with increasing severity grade.
Cytotoxicity and hyperplasia were not observed and consequently, the observed changes were considered adaptive responses rather than adverse effects. There were no other test substance-related histological changes.

Table 5.8.2-7: An 8-Week Oral (Diet and Gavage) Toxicity Study of Citric Acid in Male Rats ([redacted] 2010): Histological findings

	Gavage administration		Dietary administration		
	Aqueous control	**791-1316 mg/kg bw/day citric acid**	**Basal diet control**	**Low pH diet, 14,000 ppm citric acid**	**High pH diet, 21,400 ppm trisodium citrate dihydrate**

minimal	8	6	5	0	4
mild	1	3	2	6	5
moderate	0	1	0	4	0
Average severity [b]	**1.1**	**1.5**	**0.9**	**2.4****	**1.4**

[a] number of tissues examined from each group
[b] 1= minimal, 2= mild and 3= moderate; animals without a histological change were assigned a severity score of 0
** significantly different from relevant control group ($p<0.01$) using the Mann-Whitney U-Test

Study conclusion
Citric acid administered orally via gavage or diet and trisodium citrate dihydrate administered via the diet to Sprague Dawley rats for 56 days resulted in higher parotid salivary gland weights and a generally correlative increase in severity of background cytoplasmic alterations in the parotid salivary glands at all dose levels with equivalent citrate ion doses (791-1316 mg/kg bw/day gavage citric acid, 14000 ppm diet citric acid, and 21400 ppm diet trisodium citrate dihydrate). These effects were noted as most severe in the low pH dietary test group. In the absence of cytotoxicity and hyperplasia the noted effects are considered an adaptive response rather than an adverse effect and are consistent with the hypothesis that low pH diets result in adaptive cellular responses within the salivary glands.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Higher parotid salivary gland weights and histological alterations were noted as statistically significant in the low pH citric acid diet administered to Sprague Dawley rats. This proof of concept study is considered supportive evidence that low pH diets result in adaptive salivary gland alterations, as noted in some glyphosate acid repeat dose dietary studies.

2. Full summary

The purpose of this study was to investigate the rat strain susceptibility of the effects of glyphosate acid on the salivary gland after 4 weeks administration in these strains of rat. In studies with F344 rats, glyphosate acid has been shown to cause effects on the salivary gland (NTP, 1992[38]). In contrast, there was no evidence of microscopic changes in the salivary gland in a previously conducted 28 day feeding study with glyphosate acid (20000 ppm in the diet) in Alpk:AP$_f$SD rats, although there was an effect on gland weight ([redacted] 1995)[39].

Study groups of 24 male Alpk:AP$_f$SD (Wistar-derived; AP), Sprague-Dawley (Charles River CD; CD) and Fischer 344 (F344) rats received 0 or 20000 ppm glyphosate acid. Eight animals from each group were killed on Day 29 and the remaining animals were retained without treatment for a further 4 (8 rats/group) or 13 weeks (8 rats/group). Clinical observations, bodyweights and food consumption were measured and at the end of the scheduled periods, the animals were killed and subjected to a necropsy. Salivary glands were weighed and taken for subsequent histopathology examination.

Treatment with 20000 ppm glyphosate acid produced significant reductions in bodyweight and minor reductions in food consumption in AP and CD rats but no effects on bodyweight or food consumption were seen in the F344 rat. In contrast, salivary gland weight was unaffected in the CD rat but was increased in both AP and F344 rats at the end of the administration period. Microscopic examination of the salivary glands showed the most pronounced effect occurred in the F344 strain where there was diffuse cytoplasmic basophilia and enlargement of the parotid acinar cells. Similar but slight effects involving small foci of cells only occurred in the AP and CD strains.
Recovery of effects was apparent in all strains during the recovery periods. Bodyweight and food consumption returned to control values in both AP and CD strains. After four weeks on control diet, significant recovery of the salivary gland changes, in terms of both weight and micropathology, was evident in the F344 strain and the AP and CD rats were indistinguishable from their corresponding controls. After 13 weeks on control diet slightly more treated F344 rats showed minor focal changes in the salivary gland compared to the contemporaneous controls and group mean salivary gland weights were increased slightly.
Administration of diets containing 20000 ppm glyphosate acid to male rats for 4 weeks produced marked strain differences in the severity of effect in the parotid salivary gland. Microscopic examination of the salivary glands showed the most pronounced effect in the F344 strain. Similar but slighter effects occurred in the AP and CD strains.
Complete recovery of effects were apparent in AP and CD strains following the 4-week recovery period and significant recovery had occurred in the F344 strain. It is not clear whether the slightly higher incidence of minor focal changes in the salivary glands of the F344 strain after 13-week recovery was a residual effect of treatment or represented the random variation in the background incidence in this strain.

B. STUDY DESIGN AND METHODS

In life dates: 1996-01-15 to 1996-05-14

Animal assignment and treatment

In a 28 days feeding study groups of 24 male Alpk:AP$_f$SD (Wistar-derived; AP), Sprague-Dawley (Charles River CD; CD) and Fischer 344 (F344) rats received 0 or 20000 ppm glyphosate acid. Eight animals from each group were killed on Day 29 and the remaining animals were retained without treatment for a further 4 (8 rats/group) or 13 weeks (8 rats/group).

Two test diet batches were prepared prior to start of treatment by mixing 1255 g test substance to 58.745 kg diet and blending. Samples of both preparations were analysed to verify the achieved concentration.

Clinical observations
Cage-side observations were performed daily. A detailed physical examination was performed prior to administration and weekly thereafter. Detailed clinical examinations were performed at the same time as body weights were recorded.

Body weight
Individual body weights were recorded on start of administration and weekly thereafter.

Food consumption and compound intake
Food consumption was recorded continuously throughout the study for each cage of rats and calculated as a weekly mean (g food/rat/day) for each cage.

Sacrifice and pathology
All animals were killed by halothane anaesthesia and subjected to a gross examination of the salivary glands. The salivary glands were weighed (left and right separately) and microscopically examined (left) in animals surviving until the end of the study.

Statistics
All data were evaluated using analysis of variance and/or covariance by the GLM procedure in SAS (1989). Least-squares means for each group were calculated using the LSMEAN option in SAS PROC GLM. Unbiased estimates of differences from control were provided by the difference between each treatment group least-squares mean and the control group least-squares mean. Differences from control were tested statistically by comparing each treatment group least-squares mean with the control group least-squares mean using a two-sided Student's t-test, based in the error mean square in the analysis.

II. RESULTS AND DISCUSSION

A. ANALYSIS OF DOSE FORMULATIONS
The mean achieved concentration of glyphosate acid in both batches of diet was within 2 % of the target concentration (see table below).

Table 5.8.2-8: Glyphosate Acid: Comparison of Salivary Gland Effects in Three Strains of Rat ([redacted] 1996): Achieved concentrations of glyphosate acid in the diet

	Nominal concentration (ppm)	Mean analysed concentration (ppm)	% of nominal concentration
Batch 1	20,000	19,985	99.9
Batch 2	20,000	20,355	101.8

B. MORTALITY
There were no treatment-related deaths. One treated AP rat was killed in Week 7 following accidental damage to its snout.

C. CLINICAL OBSERVATIONS
There were no treatment-related findings in any of the groups noted during the study period.

D. BODY WEIGHT
AP rats
During the administration period significantly lower group mean bodyweight than for control was seen. At the end of the administration period the difference was approximately 7 %. The reduction in bodyweight was maintained during the 4-week recovery period (approximately 7 % at the end of Week 9) but no

differences in bodyweight were apparent by the end of the 13-week recovery period.

CD rats
Group mean bodyweights for treated animals were significantly reduced during the administration period in comparison to controls. The reduction in bodyweight was approximately 7 % (after adjusting for initial bodyweight) at the end of the administration period. However, bodyweights quickly recovered and were approximately 4 % lower (not statistically significant, after adjusting for initial body weight), compared with control, after the 4-week recovery period, and 5 % higher than controls (after adjusting for initial body weight) by the end of the 13-week recovery period.

F344 rats
No treatment related effects were observed.

E. FOOD CONSUMPTION
AP rats
Overall, food consumption in the treated group tended to be slightly lower than the control during the administration period although this achieved statistical significance only in Week 7. No effects were seen at the end of the recovery period.

CD rats
Group mean food consumption for treated animals was generally lower than controls during the administration period, reaching statistical significance in Week 2 and 4. Food consumption for the recovery animals returned to control levels by Week 8.

F344 rats
There was no evidence of any treatment related effects.

F. NECROPSY
Organ weights
There was no evidence of any effects of glyphosate acid on the salivary gland weight at any time point in CD rats. On the contrary, salivary gland weights were increased in the treated AP and F344 rats at the end of the administration period in comparison to control. While no effects were noted in the 4- or 13-week recovery AP animals, in F344 rats the salivary gland weights were still increased at these time points, although there was clear evidence of recovery.

Table 5.8.2-9: Glyphosate Acid: Comparison of Salivary Gland Effects in Three Strains of Rat ([redacted]., 1996): Mean salivary gland weights at necropsy

Organ	AP		CD		F344	
	0	20000 ppm	0	20000 ppm	0	20000 ppm

Weight after 4 week recovery (g)						
Left salivary gland	0.748	0.703	0.844	0.742	0.488	0.555
Right salivary gland	0.639	0.623	0.701	0.637	0.428	0.505*
Weight after 13 week recovery (g)						
Left salivary gland	0.750	0.760	0.790	0.819	0.623	0.612
Right salivary gland	0.669	0.681	0.668	0.705	0.495	0.528

* Statistically significant difference from the control group mean at $p<0.05$(Student's t-test, two-sided).
** Statistically significant difference from the control group mean at $p<0.01$ (Student's t-test, two-sided).
n = 8 animals/study group

Macroscopic findings
No macroscopic abnormalities were seen in salivary glands in any rat, either at the end of the administration period or after the 4- or 13-week recovery periods.

Microscopic findings
Treatment-related findings were confined to the parotid salivary gland and comprised alteration in the staining of the cytoplasm of the acinar cells. The affected cells appeared strongly basophilic and enlarged (recorded as basophilia of parotid acinar cells).
At the end of the four-week administration period, this change was most prominent in F344 rats. All rats showed marked cytoplasmic basophilia that was diffuse, involving the whole of the parotid gland. However, no evidence of cell degeneration or necrosis was seen. Most of the control F344 rats also showed a minor degree of basophilia involving occasional acinar cells only.
The other two strains, AP and CD, both showed the same effect in the parotid gland after four weeks of treatment, but at a much reduced severity compared to the F344. In addition, the distribution was different in that only small focal groups of acinar cells were affected in the AP and CD rats in contrast to the diffuse involvement seen in the F344. The effect was weakest in the CD rat.

The incidence data at the end of the administration period indicate that the background change varies in control rats in the three strains. None was seen in the AP controls, there was a single CD control rat with a minimal focal change, whereas 7 out of 8 F344 controls showed minor changes.
After four weeks recovery in the F344 strain the severity of the parotid basophilia was reduced to minimal or slight and affected small foci of acinar cells only. No changes were seen in the CD rats and only a single AP rat showed a minimal change. As an AP control rat showed changes at this time point this is considered not to be related to treatment.
After 13 weeks recovery no treatment-related changes were seen in the AP and CD strains. Slightly more of the F344 rats showed minor focal changes compared to the corresponding control group but this may reflect variations in the background spontaneous change rather than a residual effect of treatment.

Table 5.8.2-10: Glyphosate Acid: Comparison of Salivary Gland Effects in Three Strains of Rat ([redacted] 1996): Histopathological findings in salivary glands

Finding	AP		CD		F344

*number of animals affected / total number of animals examined

Study conclusion
Administration of diets containing 20000 ppm glyphosate acid to male rats for 4 weeks produced marked strain differences in the severity of effect in the parotid salivary gland. Microscopic examination of the

salivary glands showed the most pronounced effect occurred in the F344 strain where there was diffuse cytoplasmic basophilia and enlargement of the parotid acinar cells. Similar but slighter effects occurred in the AP and CD strains involving small foci of cells only.
Complete recovery of effects was apparent in AP and CD strains following the 4-week recovery period and significant recovery had occurred in the F344 strain. It is not clear whether the slightly higher incidence of minor focal changes in the salivary glands of the F344 strain after 13-week recovery was a residual effect of treatment or represented the random variation in the background incidence in this strain.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Administration of diets containing 20000 ppm glyphosate acid to male rats for 4 weeks produced marked strain differences in the severity of effect in the parotid salivary gland. Microscopic examination of the salivary glands showed the most pronounced effect occurred in the F344 strain where there was diffuse cytoplasmic basophilia and enlargement of the parotid acinar cells. Similar but slighter effects occurred in the AP and CD strains involving small foci of cells only. A complete recovery from the effects on the salivary gland was observed in the AP and CD strains following a 4-week recovery period. A significant, though incomplete, recovery had occurred in the F344 strain, supporting the hypothesis that low pH diets induce a non-adverse adaptive response in salivary glands. Following a 13-week recovery period a slightly higher incidence of minor focal changes in the salivary glands of the F344 strain treatment group was noted, compared with the F344 strain control group and compared with the AP and CD strain. The study is considered acceptable.

Assessment and conclusion by RMS:

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	1996
Report title	Glyphosate Technical: Pharmacology Screening Study in the Rat
Report No	434/021
Document No	Not reported.
Guidelines followed in study	JMAFF, 59 Nohsan No. 4200 (1985)
Deviations from current test guideline	Not applicable.
Previous evaluation	Yes, accepted in RAR (2015).
GLP/Officially recognised testing facilities	Yes, conducted under GLP.

Acceptability/Reliability:	Valid
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

The test material was evaluated for evidence of pharmacological activity using a series of *in vivo* and *ex vivo* screening methods. For *in vivo* studies five male and five female rats were dosed with glyphosate technical at a dose level of 5000 mg/kg with similar sized control groups receiving vehicle only. Approximately one hour after dosing control and treated animals were examined for either haematological changes, electrocardiographic changes or behavioural/functional changes. *Ex vivo* studies on the isolated guinea pig ileum and isolated rat gastrocnemius muscle were performed using saturated solutions of the test material.

***In vivo* studies**
There were no differences in response between treated and control animals.

***Ex vivo* studies**
Glyphosate Technical (12 mg/mL) caused a contractile response to isolated guinea pig ileum similar to that seen with acetylcholine. The effect seen was abolished when the ileum was pre-incubated with atropine sulphate.
Injection of tubocurarine resulted in a significant diminution of the contractile response of the rat gastrocnemius muscle when the sciatic nerve was stimulated. On the contrast, there was no effect on muscle contraction when either glyphosate technical or physiological saline was injected.

Conclusion
At a maximum oral gavage dose level of 5000 mg glyphosate technical/kg bw there were no effects seen from the *in vivo* screens performed. When administered to the isolated guinea pig ileum glyphosate technical caused a contractile response similar to that seen with known parasympathomimetic agents. Evaluation of innervated muscle response showed that glyphosate technical, when administered at the maximum solubility concentration in physiological saline, did not cause any neuromuscular blocking activity.

I. MATERIALS AND METHODS

A. MATERIALS

Test materials:

Identification:	Glyphosate Technical	
Description:	White powder	
Lot/Batch #:	H95D161A	
Purity:	95.3 %	
Stability of test compound:	No data given in the report.	
Vehicle and/ or positive control:	*in-vivo*	1 % carboxymethyl cellulose
	ex-vivo (guinea pig)	distilled water, krebs physiological buffer solution,
	ex-vivo (guinea pig)	physiological saline

Test animals:

in-vivo	Species:	Rats

Strain:	Sprague-Dawley (CD)
Source:	[redacted]
Age:	no data
Sex:	Males and females
Weight at dosing:	176 - 200 g
Acclimation period:	At least 6 days
Diet/Food:	SQC Rat and Mouse Diet No.1 Expanded (Special Diets Services Ltd., Witham Essex, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	By sex in groups of five in polypropylene cages with stainless steel grid floors.
Environmental conditions:	Temperature: 19 – 25 °C Humidity: 40 – 75 % Air changes: at least 15/hour Photocycle: 12 hours light/dark cycle
ex-vivo Species:	Guinea pig
Strain:	Dunkin Hartley
Source:	[redacted]
Age:	no data
Sex:	Males
Weight at dosing:	250 - 300 g
Acclimation period:	no data
Diet/Food:	Guinea Pig FDI Diet (Special Diets Services Ltd., Witham Essex, UK), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	By sex in groups of up to three in polypropylene cages with solid floors and sawdust bedding.
Environmental conditions:	Temperature: 17 – 23 °C Humidity: 30 – 70 % Air changes: at least 15/hour 12 hours light/dark cycle
in-vivo Species:	Rats
Strain:	Sprague-Dawley (CD)

Environmental conditions: Temperature: 19 – 25 °C
Humidity: 30 – 70 %
Air changes: at least 15/hour
Photocycle: 12 hours light/dark cycle

B. STUDY DESIGN AND METHODS

Test material preparation

In vivo

The test material was suspended daily in 1 % carboxymethyl cellulose (vehicle) by weighing an amount into a suitable container and adding vehicle to make the appropriate final volume. Homogeneity was assured by mixing the formulations with a Silverson mixer/homogeniser.

Ex vivo – Guinea pig ileum

The test material was dissolved initially in distilled water and subsequently in freshly prepared Krebs physiological buffer solution. A saturated solution was used. The test material/buffer solution was shaken until the test material was dissolved.

Ex vivo – Rat gastrocnemius muscle

The test material was dissolved in sterile physiological saline. A saturated solution was used. The test material/vehicle was shaken until the test material was dissolved.

The test material was dissolved at the maximum solubility of 12 g/L for all *ex vivo* studies.

Methods for *in vivo* studies

Dose rationale

The selected dose level (5000 mg/kg bw) was based on the results of an acute oral toxicity study in rats previously conducted by the laboratory.

Group allocation and dosing

Animals were dosed by oral gavage administration once only on the day allocated for each dose group as determined by the type of evaluation specified.

Table 5.8.2-11: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted], 1996): Study design

Group	Males	Females	Evaluation	Dose (mg/kg bw)	Dose volume (mL/kg bw)
1	5	5	Haematology	0*	10
2	5	5		5000	10
3	5	5	Electrocardiography	0*	10
4	5	5		5000	10
5	5	5	Behaviour/functional tests	0*	10
6	5	5		5000	10

*Control animals were treated with vehicle only.

Haematology

Approximately one hour after dosing blood samples were taken via a marginal tail vein from all animals from Groups 1 and 2. The blood was collected into tubes containing Potassium EDTA anticoagulant. For measurement of clotting (prothrombin) time samples were collected into tubes containing sodium citrate (0.11 mol/L).

The following parameters were evaluated: Haemoglobin (Hb), Total erythrocyte count (RBC), Haematocrit

(Hct), Mean Corpuscular Haemoglobin (MCH), Mean Corpuscular Volume (MCV), Mean Corpuscular Haemoglobin Concentration (MCHC), Total Leucocyte Count (WBC), Platelet Count (PIT), Clotting (Prothrombin) time (CT).

Electrocardiography (ECG)
Approximately one hour after dosing animals from Groups 3 and 4 were anaesthetised using halothane anaesthesia and assessed for cardiac activity using an electrocardiograph. A limb lead was attached to each limb and connected to the electrocardiogram. The equipment was set to lead II measurement at a sensitivity of either 10 mm/mvolt or 5 mm/mvolt and a chart speed of 25 mm/second. Alternative control and treated animals were evaluated.

The following parameters are measured: Heart rate, P-R interval, QRS interval, Q-T interval, P-amplitude, R-amplitude, and T-amplitude.

Behavioural/functional tests
Approximately one hour after dosing animals from Groups 5 and 6 were placed individually in a purpose built arena and assessed for behaviour and response to various stimuli using a modified Irwin Screen.

The following observations were performed: salivation, hypo/hyperthermia, skin colour, respiration, lacrimation, palpebral closure, piloerection, exophthalmia, gait, twitches, tremors, convulsions, abnormal behaviour, tail elevation, transfer arousal, urination count, defaecation count and vocalisation count.
The following manipulative tests were performed: Finger Approach, Touch Escape, Tail Pinch, Toe Pinch, Grasp Response, Auditory Startle Response, Pupil Response to Light and Palpebral Reflex.

Evaluation of isolated guinea pig ileum
Sections of ileum were dissected from previously untreated guinea pigs killed by cervical dislocation. The sections of ileum were transferred to a purpose-built isolated organ bath containing Krebs buffer solution. The isolated ileum was connected to the lever arm of an isotonic transducer by a cotton ligature. The transducer was connected to a chart recorder. Contractions of the isolated ileum could then be recorded. Standard solutions of acetylcholine, a known agonist, were prepared and added to the volume of buffer solution used to bathe the isolated ileum. A maximum volume of 2 mL was used for all experiments to ensure the integrity of the tissue in the medium. The contraction response of isolated ileum was recorded for each concentration of acetylcholine to produce a standard curve. Between the addition of each new concentration of acetylcholine, the buffer in the organ bath was flushed out and replaced by fresh buffer. The test material, dissolved in buffer, was added and its response compared with standards.
Following initial results, an antagonist (atropine) to the effects of acetylcholine was added together with the agonist. The results were then compared with the effects of only an antagonist added to the test material.

The following were recorded: response to acetylcholine (agonist, sympathomimetic), response to test material, response to atropine (antagonist) and acetylcholine (agonist), and response to atropine (antagonist) and test material.

Evaluation of rat gastrocnemius muscle
Previously untreated rats were killed by cervical dislocation. The abdomen was immediately dissected open and the dorsal aorta exposed. A butterfly needle was inserted into the dorsal aorta, near to the bifurcation in a posterior direction.
A volume of 0.3 mL of lithium heparin at a concentration of 10 mg/mL in sterile saline was injected into the dorsal aorta followed by 0.5 mL of sterile saline. The gastrocnemius muscle of the hind limb was exposed with the sciatic nerve intact. The gastrocnemius muscle was detached from the ankle joint and this area was ligated with cotton, which was then attached to the lever arm of a transducer. The limb was held in place by a series of pins. An electrical stimulus of 12 volts was applied to the sciatic nerve and the muscle response was recorded. This action was repeated at approximately twelve—second intervals until sufficient responses had been recorded.
The experiment was repeated on separate animals with doses of tubocurarine (positive control) injected into

the dorsal aorta instead of sterile saline. The experiment was also repeated on a separate animal with the test material dissolved in sterile saline.

The following were recorded: Response to injection of sterile saline, response to injection of tubocurarine, and response to injection of test material.

Evaluation of data

In vivo

Data were processed to give group mean values and standard deviations where appropriate.

Evaluation of electrocardiographic outputs

All measurements were performed using a vernier calliper with digital readout. All measurements were recorded twice in order to minimise operator bias.

Isolated guinea pig ileum

The final concentration of test material in the organ bath was based on the serial dilution value plus the additional dilution in the total volume of the organ bath (50 mL).

II. RESULTS AND DISCUSSION

In vivo studies

Evaluation of blood parameters

There were no biologically significant differences, among the parameters measured, between treated and control animals.

Table 5.8.2-12: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted], 1996): Group mean haematology values

Parameter	0 mg/kg bw		5000 mg/kg bw

Evaluation of cardiovascular system

One female of the control group had cardiac arrhythmia characterised by extra systoles. There were no biologically significant differences in the mean values recorded during electrocardiography (ECG) for wave amplitudes, wave intervals or heart rate.

Table 5.8.2-13: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted], 1996): Group mean ECG values

Group Sex	Dose		Amplitude (mv)			Interval (msec)			Heart rate (bpm)

bpm = beats per minute, SD = standard deviation

Behavioural and functional tests

There were no biologically significant differences in behaviour and response to manipulative tests. The intergroup variances in response were considered to be within normal variation for this model.

Table 5.8.2-14: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted], 1996): Group mean summary of behavioural assessments*

Parameter	0 mg/kg bw														5000 mg/kg bw													
	Male (n=5)							Female (n=5)							Male (n=5)							Female (n=5)						
	Number of animals classified as (score)																											
	0	1	2	3	4	5	6	0	1	2	3	4	5	6	0	1	2	3	4	5	6	0	1	2	3	4	5	6
Transfer arousal					5							5					1		4							4		
Tail elevation										5															4	1		
Finger approach					4		1					5					2		3							4		1
Touch escape			1		1		3					1		4					4		1					3		2
Tail pinch			1		4												2		3									
Grasp response			4		1			2		1		2			1		2		2			2		2		1		
Vocalisation	4		1					2		2			1		4			1				2	2	1				
Toe pinch					2		3													1	4							

Comment of assessor: only parameters with values differing between treated and control groups listed: no differences between treated and control groups were seen for all other behavioural/functional parameters that had been assessed. Scores 0-6 were not clearly explained in study report, however higher scores were indicative for higher grade of activity.

Evaluation of isolated guinea pig ileum

The addition of acetylcholine to the medium containing the isolated guinea pig ileum resulted in contraction of the tissue in a concentration—related response. Incubation with atropine sulphate immediately prior to addition of acetylcholine reduced or stopped the contraction response in a concentration related manner.
The addition of Glyphosate Technical at the maximum solubility in buffer also resulted in contraction of the ileum. The force of contraction was increased by an increasing volume of the test material in solution. Incubation with atropine sulphate prior to addition of Glyphosate Technical also resulted in the lack of a contractile response.

Table 5.8.2-15: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted], 1996): Response of guinea pig ileum to a known agonist and glyphosate

Agonist		Height of response (mm)	% of maximum response
Test material	**Final concentration**		
Acetylcholine bromide	2.2×10^{-6} m	39	100
	1.8×10^{-6} m	33.5	85.9
	1.5×10^{-6} m	25.5	65.4
	1.0×10^{-6} m	15	38.5
Glyphosate (in distilled water)	4.26×10^{-4} m	7	17.9

Evaluation of rat gastrocnemius muscle

Injection of tubocurarine, a known neuromuscular blocking agent, at a concentration of 25 mg/mL resulted in a significant reduction of the contractile response of the rat gastrocnemius muscle when the sciatic nerve was stimulated. There was no effect on muscle contraction when either Glyphosate Technical (12 mg/mL) or physiological saline was injected. The difference in force of response seen with Glyphosate Technical and physiological saline can be attributed to individual animal variation.

Table 5.8.2-18: Glyphosate Technical: Pharmacology Screening Study in the Rat ([redacted] 1996): Comparison of force of contraction of innervated skeletal muscle (gastrocnemius)

Test material	Concentration	Range of response in mm (n = 5)	Average response (mm)	% of control
Physiological saline		21 - 28	24.8	100
Tubocurarine	25 mg/mL	3 - 6	4.6	18.5
Glyphosate Technical	12 mg/mL	23 - 38	32.4	130.6

Study conclusion
At a maximum dose level of 5000 mg/kg bw glyphosate technical no effects were seen in the *in vivo* screens performed. When administered to the isolated guinea pig ileum *ex vivo*, glyphosate technical concentrations at millimolar (mM) levels caused a contractile response similar to that seen with a known parasympathomimetic agent at micromolar (µM) levels.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
In vivo
At a maximum dose level of 5000 mg glyphosate technical/kg bw no biologically relevant effects on the treated animals were seen in the *in vivo* screens performed. During extensive clinical observations parameters indicative for a disturbance of the animal's health status, such as hypo/hyperthermia, skin colour, lacrimation, respiration, palpebral closure, and salivation were similar between vehicle control and treated rats. This confirmed that the selected dose level had no toxic effect on the rats. The intergroup variances in response to manipulative tests can be considered as normal biological variation.
Similarly, there were no relevant differences between treated and control animals in the haematological and cardiac parameters measured.

Ex vivo: Muscle contractibility
Evaluation of innervated rat gastrocnemius muscle response showed that glyphosate, when administered at the maximum solubility concentration in physiological saline, did not cause any neuromuscular blocking activity. The effect of glyphosate technical was directly compared to that of a known neuromuscular blocking agent (atropine sulphate), which caused a significant reduction in the muscle response to electrical stimulation of the sciatic nerve.

Ex vivo: Intestinal contractibility
Addition of acetylcholine as a positive control substance to isolated guinea pig ileum resulted in contraction in a concentration-dependent response at micromolar (µM) concentrations. Atropine sulphate immediately prior to addition of acetylcholine reduced or stopped the contraction response in a concentration related manner. This confirmed the reliability of the methodology. Glyphosate caused a contractile response of isolated guinea pig ileum at much higher millimolar (mM) concentrations, which could be antagonized with atropine. Thus, a parasympathomimetic activity of glyphosate was observed in this *ex vivo* model at high concentrations.

The study used appropriate negative control animals, as well as appropriate positive control substances (agonists and antagonists). The age of study animals was not stated. The study is considered acceptable.

2. Full summary

Effects of a single intraperitoneal (mice) or single intravenous (rabbits) administration of the ammonium salt of glyphosate (purity: 94.78 %) on clinical appearance, and nervous, respiratory and circulatory system were assessed. Groups of three male and female ICR mice (15 male and 15 female in total) received 78, 313, 1250, or 5000 mg glyphosate/kg bw intraperitoneally. Groups of three male rabbits (30 male in total) received 7.81, 31.3, 125 or 500 mg glyphosate/kg bw intravenously. Mice and half of the male rabbits were clinically observed at frequent intervals after dosing for up to seven days. The other half of male rabbits was used for digital monitoring of respiratory and circulatory parameters under urethane-anaesthesia.

At the top dose levels, all mice died within 0.5 hours and all anesthetized rabbits within a few minutes after injection. Non-anesthetized rabbits survived intravenous application of 500 mg/kg bw (dose resulting from highest water soluble concentration) although animals showed decrease in spontaneous activity and increase in respiratory rate. The rabbits completely recovered within 3 hours. In rabbits, which died, heart rate, blood pressure and respiratory rate decreased and voltage of QRS complex in electrocardiogram were noted. At the next lower dose levels (1250 mg/kg bw in mice or 125 mg/kg bw and 31.3 mg/kg bw in rabbits, respectively), transient symptoms like a decrease in blood pressure, reduced activity and neuromuscular signs were observed but cleared to normal values or behaviour within some hours at the latest. No abnormalities were observed in mice dosed at 313 mg/kg bw or less and in rabbits dosed at 7.81 mg/kg bw.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:	Ammonium salt of glyphosate (MON-8750)
Identification:	Not stated
Description:	Not stated
Manufacturer	Not stated
Lot/Batch #:	RUD-9201-3544F
Purity:	94.78 %
Storage conditions:	Sealed container in a refrigerator
Stability of test compound:	Not stated
Vehicle:	Physiological saline (0.9 % NaCl), pH 5.0

Test animals:

Species:	Mouse
Strain:	ICR (SPF)
Source:	[redacted]
Age:	7 weeks
Sex:	Male/female
Weight at dosing:	Males: 32 - 41 g, females : 26 - 33 g
Acclimation period:	At least 7 days
Diet/Food:	Certified pelleted diet MF (Oriental Yeast Co., Ltd., Tokyo), *ad libitum*
Water:	Water from a private well passed through precipitating and sedimentary procedures and sterilized by ultraviolet light and chlorine, *ad libitum*
Housing:	Three mice per aluminium cage
Environmental conditions:	Temperature: 22 ± 1 °C Humidity: 55 ± 5 % Air changes: 15/hour (all fresh air system) Photocycle: 12 hours light/dark cycle

Test animals:

Species:	Rabbit
Strain:	Japanese white strain (SPF)
Source:	[redacted]
Age:	10 weeks
Sex:	Males
Weight at dosing:	2.3 - 2.8 kg (clinical observation group) 2.4 - 3.0 kg (respiration, blood pressure, ECG group)
Acclimation period:	At least 7 days
Diet/Food:	Certified pelleted diet RC4 (Oriental Yeast Co., Ltd., Tokyo), *ad libitum*
Water:	Same as for mice
Housing:	Individually in aluminium cage
Environmental conditions:	Same as for mice

B. STUDY DESIGN

Table 5.8.2-19: Ammonium Salt of Glyphosate (Mon-8750): General Pharmacological Study ([redacted], 1992): Animal assignment and treatment

Parameter investigated	Species	Sex	Route	Volume (mL/kg bw)	Number of animals per dose				
					Intraperitoneal dose (mg/kg bw)				
					0	78	313	1250	5000
Clinical observation	Mouse	Male	Intraperitoneal	20	3	3	3	3	3
		Female			3	3	3	3	3
					Intravenous dose (mg/kg bw)				
					0	7.81	31.3	125	500 *
Clinical observation	Rabbit	Male	Intravenous	2	3	3	3	3	3
Respiration, blood pressure, ECG					3	3	3	3	3

ECG = electrocardiogram
Control groups received physiological saline at the same volume of administration
* highest soluble concentration for intravenous route

The test substance was dissolved in physiological saline (0.9 % NaCl) adjusting the pH to ca 5.0 by NaOH solution. Intraperitoneal and intravenous routes were chosen to achieve complete absorption of the test substance.

Clinical Observation in mice
Neuropharmacological changes of male and female mice were examined according to Irwin's method (Irwin 1967, in Animal and Clinical Pharmacologic Techniques in Drug Evaluation, Nodine and Siegler). Animals were observed prior to, and 5 min., 0.5, 1, 3, and 6 hours after dosing and then once a day for a week.

Clinical Observation in rabbits
Detailed observations were conducted according to the information/reference provided in the study report. Animals were observed prior to, and 5 min., 0.5, 1, 3, and 6 hours after dosing and then once a day for a week.

Monitoring of respiratory and circulatory parameters in rabbits
Three rabbits per dose were anesthetized with urethane (ca. 1.5 g/kg bw subcutaneous). Rabbits were hold in dorsal position. All parameters were recorded on a polygraph (RM-6000, Nihon Koden Inc., Tokyo). A homeothermic blanket (KN-474, Natsume Seisakusho Co., Ltd.) was used to keep the body temperature constant. The test substance was administered to a rabbit after steady recordings were obtained. Recordings were continued for 4 hours after dosing.

A thermistor type respiration sensor (TR-612T, Nihon Koden Inc.) was fixed to a cannula inserted into a cut opening of the trachea. Respiratory rate was measured by a digital counter (AT-601G, Nihon Koden Inc.). Blood pressure was measured via a cannula inserted into the left femoral artery connected to a high pressure transducer (TP-200T, Nihon Koden Inc.). Systolic, diastolic and mean blood pressures were measured by a digital counter (AP-611G, Nihon Kohden Inc.). ECG was recorded via electrodes fixed to the extremities by Lead II. Heart rate was measured from the pulse of blood pressure by a digital counter (AT-601G, Nihon Kohden Inc.)

Statistics
Student's t-test was used to compare a dosed group with the corresponding control group. Differences

between groups were considered to be statistically significant at the p≤0.05 level.

II. RESULTS AND DISCUSSION

A. CLINICAL OBSERVATIONS IN MICE

All mice of the top dose died within 0.5 h after application. Clinical signs observed after application consisted of manifestation of passivity, a decrease in spontaneous activity, reactivity, and pain response, clonic and tonic convulsions, a decrease in righting reflex, limb tone, body tone, abdominal tone, grip strength, corneal reflex and ipsilateral flexor reflex (IFR). In addition a decrease in alertness, abnormal posture (prone position) and abnormal skin color (cyanosis) was observed in male mice. Staggering gait was observed for females of the high dose.

At the mid dose group of 1250 mg/kg bw abnormal behaviour was observed in male and female mice for awareness, motoractivity, central nervous system (CNS), excitation, posture, motor incoordination, muscle tone, reflexes, and autonomic signs. Animals recovered within1 hour after administration.

No clinical signs were observed at the doses of 313 mg/kg bw or less.

Table 5.8.2-20: Ammonium Salt of Glyphosate (Mon-8750): General Pharmacological Study ([redacted] 1992): Summary of in vivo experiments in mice

Test			Intraperitoneal dose* (mg/kg bw)			
			78.1	313	1250	5000
Clinical observation	Male	Dead/dosed	0/3	0/3	0/3	3/3
		Abnormal signs	–	–	+	++
	Female	Dead/dosed	0/3	0/3	0/3	3/3
		Abnormal signs	–	±	+	++

* Three mice per sex and per dose were treated with a single intraperitoneal injection)
Rating: (–) no, (±) possible, (+) slight, (++) moderate, (+++) severe effect

B. CLINICAL OBSERVATIONS IN RABBITS

Rabbits in the 500 mg/kg bw dose group showed a decrease in spontaneous activity and an increase in respiratory rate within 0.5 hours after injection and completely recovered within 3 hours. No distinct abnormalities were observed at the doses of 125 mg/kg bw or less.

C. RESPIRATORY AND CIRCULATION SYSTEM IN RABBITS

A transient decrease in blood pressure during the injection was observed in rabbits treated with 31.3, 125 and 500 mg/kg bw. The decrease in blood pressure fully recovered to the control level within a few minutes after the injection at 31.3 and 125 mg/kg bw. Rabbits of the high dose groups showed a decrease in blood pressure, respiratory rate, heart rate, and a voltage of QRS complex in ECG, and died within a few minutes after the injection. The tidal volume (amplitude of respiration) was augmented after the injection. No treatment related effects were observed at 7.81 mg/kg bw.

Table 5.8.2-21: Ammonium Salt of Glyphosate (Mon-8750): General Pharmacological Study ([redacted], 1992): Summary of in vivo experiments in rabbits

Test				Intravenous dose* (mg/kg bw)			
				7.81	31.3	125	500
Clinical observation	Male	Non-anesthetized	Dead/dosed	0/3	0/3	0/3	0/3
			Abnormal signs	–	–	±	+
Respiration, Blood pressure and ECG	Male	Anesthetized	Dead/dosed	0/3	0/3	0/3	3/3
			Respiratory rate	–	–	–	+ (decrease)
			Blood	–	+	+	++ (decrease

	pressure		(decrease)	(decrease)	
	Heart rate	–	–	–	+ (decrease)
	ECG	–	–	–	+ (decrease in QRS complex)

* Three male rabbits were dosed for each test group by single intravenous injection)
Rating: (–) no, (±) possible, (+) slight, (++) moderate, (+++) severe effect

Study conclusion
Intravenous injection of the test substance produced no death in conscious rabbits at the dose of 500 mg/kg bw, which is a practically maximum dose based on its water solubility. These facts suggest that human risk after an incidental exposure of ammonium salt of glyphosate would be low in the field. It is suggested that the acute toxicity of the test substance is low. Serious hazards could not be expected in humans after an acute exposure of the test substance except for the case receiving an extraordinary large amount of the test substance.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
A pharmacological study on the toxicity of the ammonium salt of glyphosate was conducted in mice and male rabbits. The test substance was dissolved in physiological saline and adjusted to pH 5 with sodium hydroxide. Different doses up to a top dose level of 5000 mg/kg bw was administered to mice by single intraperitoneal injection. In rabbits the top dose level administered by single intravenous injection was 500 mg/kg bw, which reflected the highest soluble concentration.

At the top dose levels, all mice died within 0.5 hours and all anesthetized rabbits within a few minutes after injection. Non-anesthetized rabbits survived intravenous application of 500 mg/kg bw. They showed transient clinical abnormalities, but fully recovered within 3 hours. At the next lower dose levels transient symptoms like a decrease in blood pressure, reduced activity and neuromuscular signs were observed but cleared to normal values or behaviour within some hours at the latest. At doses up to 125 mg/kg bw in mice and 7.8 mg/kg bw in rabbits no abnormalities were noted.

Based on the available data it cannot be assessed if there was an interaction with urethane used for anaesthesia and the test substance resulting in the lethality of rabbits dosed at the top dose or whether the surgery together with the high dose resulted in the mortality. The study is however not relevant for classification purposes and does also not need to be considered in human risk assessments.

2. Full summary

The toxicodynamics of glyphosate were examined in rats by the measurement of heart rate, ECG, venous- and arterial blood pressure and body temperature.

The administered dose of 5000 mg/kg bw glyphosate, a dose close to the oral LD_{50} in rats according to the literature, killed the animals narcotised with chloralose-urethane mixture within 2 to 7 hours. After treatment, decreased pulse and respiratory rate was observed along with decreased systemic arterial pressure. ECG-II and venous pressure changes were incidental and insignificant. The mean median mercury pressure of the artery carotis was 102 mm Hg before treatment, 73 mm Hg and 54—55 mm Hg one hour and 2-3 hours after treatment, respectively. Body temperature was unchanged due to the applied experimental procedure. White spots were seen in the edges of livers of the dead animals. Microscopically, the spots were free of erythrocytes. When blood samples were haemolysed with distilled water and analysed spectrophotometrically, an absorption maximum of 567 nm was found. The haematin hydrochloride peak was recorded at 680 nm.

B. STUDY DESIGN AND METHODS

The reported acute oral lethal dose of glyphosate is 4900 mg/kg bw in rats. For the present study 5000 mg/kg bw was selected as the dose so that the dose would terminate the animals within a day, and allow sufficient time for observations before death.

Anaesthesia was carried out by IV injection of an aqueous solution containing chloralose-urethane in a 1:5 ratio. Injection volume depended on the degree of anaesthesia. The trachea was prepared by a medium incision on the neck and cannulated. To record the respiratory rate and volume the cannula was connected to a Hellige pulsotachometer.

Blood pressure in the left articular carotis was recorded by an 8-channel Hellige polygraph, supplemented with a Statham transducer-electromanometer, with a selector for continuous systolic diastolic and medium pressure. Venous pressure of the right ventricular jugular at the thoracic level was also recorded by the Statham head electromanometer polygraph. Heparin was administered into the cannula only. Lead ECG-II was recorded continuously by means of electrodes positioned into the paw of the animals. Body temperature was measured by a rectally inserted thermistor tube connected to the polygraph.

After half an hour to allow for stabilisation of the above parameters, animals were treated with 5000 mg/kg bw test compound suspended in an aqueous solution of mucilage hydroxyacetyl cellulose. Recordings on the Hellige polygraph were measured in the following sequence: heart rate, ECG, respiration, venous-, arterial pressure, body temperature. Recordings were made with 0.05 and 50 mm/sec paper speed. However, in case of faster recordings, values corresponding to different time intervals were indicated on the paper by hand.

II. RESULTS AND DISCUSSION

Heart rate
At study initiation the mean heart rate (derived from 10 animals) was 462 ± 40 min^{-1} (a level acceptable in anaesthetised rats). One hour after administration of 5000 mg/kg bw glyphosate the mean pulse rate decreased by about 5 %. The mean pulse rate consisted of both increased and decreased individual values, which were, perhaps, without toxicological significance, as no similar changes were observed at later time intervals.

ECG
No specific lead-II alterations were observed, although elevated ST and R waves, increased QRS, wide and spiked T wave were occasionally seen. No test compound-related, specific abnormalities were detected even before the observed reduction in systemic pressure.

Respiration rate
The pre-treatment value (58/min) was slightly decreased 1 hour after treatment (55/min). Further decreases

were seen at later time points: pulse rate at the end of the 2nd hour was 54/min (i.e. 7 % lower than at study initiation).

Venous pressure
Most values were at baseline level (around 0 mmHg), the maximum/minimum alterations were within 5 mmHg.

Arterial pressure
Values at study initiation (mean value 102 mmHg; a range of 80- 130 mmHg) decreased about 30 % after 1 hour (mean value 73 mm Hg). The mean value after 2 hours was 54 mm Hg (i.e. 50 % of study initiation value).

Gross pathology
Dosing was performed faultless in each case. Thoracic and abdominal organs were examined in all animals. Urinary vesicles were full of urine, due to the chloralose anaesthesia. No macroscopic changes were observed in animals surviving for 23 hours. In animals who survived for up to 4 to 5 hours, disseminated white spots of 2 to 5 mm size were seen, the origin of which were not in the gastric wall or intestines. Following microscopic examination, it was evident that the isolated spots were free of erythrocytes.

***In vitro* studies with blood**
Blood was brown when dissolved in physiological saline. When crystallised glyphosate was added to untreated rat blood at room temperature, a discolouration was observed which started after 2 to 3 minutes and resulted in a stable brown colour after 5 minutes. Based on visual assessment, the brown solution was unchanged and without sediment after 24 hours, and recorded a maximum absorption at 657 nm spectrophotometrically. The absorption maximum was 680 nm in the same photometer.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Half an hour after anesthetising with a chloralose-urethane mixture, male Wistar rats were administered a single dose of 5000 mg glyphosate/kg bw by oral gavage. All animals died within 2 to 7 hours. Treatment was followed by a marked decrease in arterial pressure by approximately 50 % two hours after treatment as compared to the initial values. There was no clear impact on heart rate and respiratory rate. ECG and venous pressure changes, if occurring in some animals, were considered incidental and body temperature was not affected.

While this study does provide some useful information, there are serious reporting deficiencies and errors within the report. Therefore, the study is only considered supportive.

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	1988
Report title	Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay
Report No	Not stated
Document No	Not stated
Guidelines followed in study	None stated.
Deviations from current test guideline	Not applicable. No purity or batch number of test materials given. Total dosing volume for combined tests unclear.
Previous evaluation	Yes, accepted in RAR (2015).
GLP/Officially recognised testing facilities	No, not conducted under GLP/Officially recognised testing facilities (GLP was not compulsory at the time the study was performed; non-guideline, investigative study).
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Groups of 10 male Wistar rats were administered 5000 mg/kg bw of glyphosate as a single oral dose at a constant dose volume of 10 mL/kg bw in corn oil. Three compounds were administered in combination with 5000 mg glyphosate per kg bw: a) 2,4-D sodium salt (at six dose intervals between 380 and 1200 mg/kg bw), b) isoproturon (at five dose intervals between 3200 and 5000 mg/kg bw), and c) metolachlor (at six dose intervals between 2100 and 3800 mg/kg bw). After simultaneous dosing, the rats were observed for 14 days for toxic symptoms and mortality.

Prior to simultaneous dosing, each of the three compounds were administered to groups of rats individually to measure toxic symptoms and mortality.

LD_{50} values determined for the three substances, 2,4-D sodium salt, isoproturon and metalochlor were 750, 3900, and 2700 mg/kg bw, respectively. When administered after previous administration of 5000 mg glyphosate/kg bw, LD_{50} values of the three substances were reduced to 585, 3600, and 2450 mg/kg bw, respectively.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:

Identification:	Glyphosate (technical)
Description:	White powder
Lot/Batch #:	Not stated
Purity:	Not stated
Stability of test compound:	Not stated
Other materials	a) 2-4 D, sodium salt (white powder) b) Isoproturon (white powder) c) Metolachlor (liquid)
Vehicle:	Corn oil (dose volume: 10.0 mL/kg bw)

Test animals:

Species:	Albino rat
Strain:	Wistar
Source:	[redacted]
Age:	Not stated
Sex:	Male
Weight at dosing:	130 to 160 g
Acclimation period:	Not stated
Diet/Food:	Pelleted feed (supplied by Lipton India Ltd., Bangalore), overnight fasting.
Water:	Water, *ad libitum*
Housing:	Five per cage (poly propylene cages) with husk bedding
Environmental conditions:	Temperature: 19–25 °C Humidity: 25—75 % Air changes: not reported Photocycle: 12 hours light/dark cycle

B. STUDY DESIGN AND METHODS

The test material in different doses was administered orally by gavage to groups of 10 male rats and the animals were observed for 14 days for toxic symptoms and mortality. LD_{50} was calculated by the method of Litchfield & Wilcoxon (1949). LD_{50} was determined for each of the compounds; 2-4 D, sodium salt, isoproturon and metolachlor.

After determining the LD_{50} of each test material groups of 10 rats received a single administration of glyphosate followed by 2-4 D, sodium salt, isoproturon and metolachlor. The post administration observation period was 14 days.

II. RESULTS AND DISCUSSION

A. GLYPHOSATE IN COMBINATION WITH 2-4 D, SODIUM SALT

Prior to administration in combination with glyphosate, the LD_{50} of 2-4 D, sodium salt was determined. Six groups, all containing 10 rats, were administered 2-4 D, sodium salt (380, 470, 600, 750, 940, and 1200 mg/kg bw). Reported symptoms included; salivation, ataxia, and loss of righting reflex. The LD_{50} with fiducial limits was calculated: 750 (656 to 858) mg/kg bw.

Table 5.8.2-25: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted] 1988): Mortality chart of 2-4 D, sodium salt

Number of rats	Dose (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	380	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
10	470	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
10	600	0	2	0	0	0	0	0	0	0	0	0	0	0	0	20
10	750	1	4	0	0	0	0	0	0	0	0	0	0	0	0	50
10	940	3	3	2	0	0	0	0	0	0	0	0	0	0	0	80
10	1200	4	6	-	-	-	-	-	-	-	-	-	-	-	-	100

Glyphosate (5000 mg/kg bw) was then administered in combination with 2-4 D, sodium salt (380, 470, 600, 750, 940, and 1200 mg/kg bw) to six groups all containing 10 rats. Mortalities are tabulated below. Reported symptoms included; salivation, ataxia, and loss of righting reflex. The LD_{50} of 2-4 D, sodium salt in the presence of glyphosate was calculated: 585 mg/kg bw.

Table 5.8.2-26: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted], 1988): Mortality chart for different doses of 2-4 D, sodium salt combined with glyphosate

Number of rats	Glyphosate + 2-4 D, sodium salt (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	5000 + 380	0	1	0	0	0	0	0	0	0	0	0	0	0	0	10
10	5000 + 470	1	2	0	0	0	0	0	0	0	0	0	0	0	0	30
10	5000 + 600	2	3	0	0	0	0	0	0	0	0	0	0	0	0	50
10	5000 + 750	4	4	0	0	0	0	0	0	0	0	0	0	0	0	80
10	5000 + 940	5	4	1	-	-	-	-	-	-	-	-	-	-	-	100
10	5000 + 1200	7	3	-	-	-	-	-	-	-	-	-	-	-	-	100

B. GLYPHOSATE IN COMBINATION WITH ISOPROTURON

Prior to administration in combination with glyphosate, the LD_{50} of isoproturon was determined. Five groups, all containing 10 rats, were administered isoproturon (3200, 3600, 4000, 4500, and 5000 mg/kg bw). No symptoms were recorded. The LD_{50} with fiducial limits was calculated: 3900 (3582 to 4247) mg/kg bw.

Table 5.8.2-27: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted], 1988): Mortality chart for isoproturon

Number of rats	Dose (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	3200	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
10	3600	0	2	1	0	0	0	0	0	0	0	0	0	0	0	30
10	4000	2	3	1	0	0	0	0	0	0	0	0	0	0	0	60
10	4500	2	3	3	0	0	0	0	0	0	0	0	0	0	0	80
10	5000	5	4	1	-	-	-	-	-	-	-	-	-	-	-	100

Glyphosate (5000 mg/kg bw) was then administered in combination with isoproturon (3200, 3600, 4000, 4500, and 5000 mg/kg bw) to five groups all containing 10 rats. Mortalities are tabulated below. Reported symptoms included; profuse salivation, urination and loose motion, ataxia, chromodacryorrhea, muscle paralysis. The LD_{50} of isoproturon in the presence of glyphosate was calculated: 3600 mg/kg bw.

Table 5.8.2-28: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted], 1988): Mortality chart for different doses of isoproturon combined with glyphosate

Number of rats	Glyphosate + isoproturon (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	5000 + 3200	0	2	0	0	0	0	0	0	0	0	0	0	0	0	20
10	5000 + 3600	2	2	1	0	0	0	0	0	0	0	0	0	0	0	50
10	5000 + 4000	3	5	0	0	0	0	0	0	0	0	0	0	0	0	80
10	5000 + 4500	3	6	1	-	-	-	-	-	-	-	-	-	-	-	100
10	5000 + 5000	5	5	-	-	-	-	-	-	-	-	-	-	-	-	100

C. GLYPHOSATE IN COMBINATION WITH METOLACHLOR

Prior to administration in combination with glyphosate, the LD_{50} of metolachlor was determined. Six groups, all containing 10 rats, were administered Metolachlor (2100, 2400, 2700, 3000, 3400, and 3800 mg/kg bw). Reported symptoms included; sluggishness and hunched back. The LD_{50} with fiducial limits was calculated: 2700 (2437 to 2992) mg/kg bw.

Table 5.8.2-29: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted] 1988): Mortality chart for metolachlor

Number of rats	Dose (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	2100	0	1	0	0	0	0	0	0	0	0	0	0	0	0	10
10	2400	2	1	0	0	0	0	0	0	0	0	0	0	0	0	30
10	2700	2	2	1	0	0	0	0	0	0	0	0	0	0	0	50
10	3000	1	5	1	0	0	0	0	0	0	0	0	0	0	0	70
10	3400	4	4	1	0	0	0	0	0	0	0	0	0	0	0	90

10	3800	4	6	-	-	-	-	-	-	-	-	-	-	-	-	100

Glyphosate (5000 mg/kg bw) was then administered in combination with metolachlor (2100, 2400, 2700, 3000, 3400, and 3800 mg/kg bw) to six groups all containing 10 rats. Mortalities are tabulated below. Reported symptoms included; sluggishness and hunched back. The LD_{50} of metolachlor in the presence of glyphosate was calculated: 2450 mg/kg bw.

Table 5.8.2-30: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted], 1988): Mortality chart for different doses of metolachlor combined with glyphosate

Number of rats	Glyphosate + metolachlor (mg/kg bw)	Animals died on day														Mortality (%)
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	
10	5000 + 2100	1	1	0	0	0	0	0	0	0	0	0	0	0	0	20
10	5000 + 2400	1	2	1	0	0	0	0	0	0	0	0	0	0	0	40
10	5000 + 2700	3	4	0	0	0	0	0	0	0	0	0	0	0	0	70
10	5000 + 3000	4	4	1	0	0	0	0	0	0	0	0	0	0	0	90
10	5000 + 3400	4	6	-	-	-	-	-	-	-	-	-	-	-	-	100
10	5000 + 3800	3	7	-	-	-	-	-	-	-	-	-	-	-	-	100

Table 5.8.2-31: Synergism and potentiation in rats of glyphosate (technical) of Excel Industries Ltd., Bombay ([redacted], 1988): Summary of determined LD_{50} values in male Wistar rats

	2,4-D, Na salt	5000 mg/kg bw glyphosate + 2,4-D, Na salt	Isoproturon	5000 mg/kg bw glyphosate + isoproturon	Metalochlor	5000 mg/kg bw glyphosate + metolachlor
LD_{50} (mg/kg bw)	750	585	3900	3600	2700	2450

Study conclusion
A single oral administration of glyphosate in combination with 2,4-D, sodium salt, isoproturon, or metolachlor caused no potentiation in albino rats.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Groups of 10 male Wistar rats were administered 5000 mg/kg bw of glyphosate as a single oral dose at a constant dose volume of 10 mL/kg bw in corn oil, followed by administration of different doses of three other substances, 2,4-D sodium salt, isoproturon, or metolachlor. The exact total dosing volume of combined administration was not reported.

The LD_{50} values of these three substances decreased when co-administered with glyphosate.

The value of this study is questionable, however, information on combined acute effects might be used as supplementary data.

Assessment and conclusion by RMS:

Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

Four groups consisting of five female Spanish goats were administered single doses of glyphosate acid via stomach tube at doses of 1980, 3090, 4620, and 10000 mg/kg bw. Water was used as a vehicle to give a constant dosing volume of 500 mL per animal. Four control groups of five goats each were administered water only.

All animals treated with 10000 and 4620 mg/kg bw and one animal treated with 3090 mg/kg bw died. The acute oral LD_{50} (14 days) was calculated to be 3530 mg/kg bw.

Clinical signs observed in goats that died included cessation of feeding activity, loss in body weight, abdominal distress, depression, ataxia, mild diarrhoea, and, shortly prior to death, recumbency. Pulmonary oedema to some degree was noted in several animals and was judged a terminal event.

Clinical signs observed in surviving goats included decreased feed consumption, diarrhoea, and body weight loss. Clinical signs noted in goats treated with the minimum dose included decreased feed consumption and diarrhoea. All clinical signs were absent at the end of the experiment (14–15 days).

Of the animals that survived until terminal sacrifice, those in the 3090 mg/kg bw group had mean body weights less than their respective control group. Goats in the 1980 mg/kg bw group had mean body weights similar to their respective control group. Feed consumption was not measured, but cessation of feeding activity was observed in all treatment groups.

No gross lesions that could be attributed to treatment were seen.
Histological examination was performed only on heart, liver, kidney, spleen and other tissues with grossly visible lesions from animals given glyphosate at 4620 and 3090 mg/kg bw, and of 4 sacrificed control animals. Mild to severe tubular nephrosis was the most consistent histopathological lesion observed in goats that died. 4/5 of the goats that died during the observation period had mild fatty change in the liver. Animals in the 3090 mg/kg bw group that survived lacked such lesions.

Changes of blood urea nitrogen concentration, serum creatinine concentration, and in the number of circulating segmental neutrophils were the most consistent laboratory findings at all dose levels. However, clinical chemistry parameters for surviving treated animals were similar to those of the control animals towards the end of the study.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:

Identification:	N-(phosphonomethyl)glycine (glyphosate)
Description:	White crystalline solid
Lot/Batch #:	XHJ-64, NBP1494248
Purity:	98.7 %
Stability of test compound:	>1 year at 29.5 °C
Vehicle:	Water was used to suspend the test article and to wash any residue from the container holding the dose and from the stomach tube. Total volume of water used was approximately 500 mL/goat

Test animals:

Species:	Goat
Description:	Spanish goats
Source:	[redacted]
Age:	Approximately 8 months to 4 years of age
Sex:	Females
Weight at dosing:	13.37 - 44 kg (mean bodyweight range 24.4 - 29.5 kg)
Acclimation period:	30 days
Diet/Feed:	During the initial acclimatization (outdoor): bermuda grass hay and commercial goat meal containing not less than 16 % crude protein [Purina® Goat Chow® (Coarse) (Ralston Purina Company, Gonzales, TX, USA)]. After the initial acclimatisation (indoor) the goats were fed bermuda grass only.
Water:	Fresh water and mineral salt blocks were available at all times.
Housing:	During acclimatisation: Outdoor covered pens After dosing: Indoor pens
Study initiation:	22 Dec 1980
Study termination	05 May 1981

Environmental conditions: Not reported

B. STUDY DESIGN AND METHODS

Animal assignment and treatment
Groups of female Spanish goats received the test item, glyphosate, at dose levels of 10000, 4620, 3090, and 1980 mg/kg bw by oral gavage as a single dose in a sequential manner. Initially, the test item was given to a group receiving 10000 mg/kg bw and subsequent doses were selected based on the observed responses. Control animals were treated with tap water. All goats were penned by treatment group and observed daily during pre-treatment and at least twice daily following treatment. Surviving animals were observed for 14 – 15 days after treatment. Only goats without visible evidence of active disease and weighing more than 13 kg were used in this study.

Concomitant treatments
During the initial holding period, all goats were vaccinated for enterotoxaemia, treated for internal parasites and observed for signs of disease.

Randomization
All goats available for experimental use were ranked according to increasing bodyweight. The resulting ranking was divided into 5 nearly equal groups. Treatment and control groups of 5 goats each were formed by randomly selecting 1 goat from each of the 5 divisions of the ranking in order that the resulting groups would h representative with respect to bodyweight of the pool from which they were selected.

Body weight
Body weights were determined prior to dosing and for surviving animals on post-dosing days 7 and 14.

Sampling time points
Blood samples were collected on 3 separate days during pre-treatment and after dosing (designated as day 0) on days 1, 3, 7, and 14. Additional samples were then taken at unscheduled times when dictated by clinical signs or evidence of impending death.

Clinical biochemistry
Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) and allowed to clot at ambient temperature; the serum was separated by centrifugation. Serum lactic dehydrogenase activity, creatine phosphokinase activity, and glucose concentration was determined as soon as possible after sample collection.
An atomic absorption spectrophotometer (Perkin Elmer Model 403, Perkin-Elmer Corp.) was used to determine serum levels of calcium, magnesium, potassium, and sodium as outlined in the manufacturer's manual. Serum levels of glucose, urea nitrogen, total protein, alkaline phosphatase, lactic dehydrogenase, and glutamic oxaloacetic transaminase were determined on automated equipment (Gilford model 3500 computer directed analyser, Gilford Instruments, Inc.) according to manufacturer's procedures. Four other serum components were determined with the same automated equipment; however, different procedures and reagents were used for these determinations, i.e., inorganic phosphorous (Inorganic Phosphorous Reagent, Worthington Diagnostics), cholinesterase (Reagent Set Kit, Biodynamics/BMC Div), gamma-glutamyl transferase (Reagent Set Kit, Biodynamics/BMC Div), and creatine phosphokinase (CK-NAC Reagent Set Kit, Biodynamics/BMC Div.). Serum creatinine and serum uric acid were determined on automated equipment according to manufacturer's procedures (Technicon Auto Analyser, Technicon Corporation).

Haematology
Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) containing disodium ethylenediamine-tetraacetate. Blood smears for differential leukocyte counts were made immediately from blood containing no anticoagulant and stained with Wright's stain (Hema-Tek

Slide Stainer, Ames Company). One hundred leukocytes were classified. Haemoglobin concentration was measured as cyanmethaemoglobin with a haemoglobinometer (Coulter Hemoglobinometer, Coulter Electronics). Erythrocyte count, mean corpuscular volume, haematocrit and total leukocyte count were determined with an electronic particle counter (Coulter Model ZBI with MCV/Hemat Computer and Channelyzer). Mean corpuscular haemoglobin and mean corpuscular haemoglobin concentration values were calculated.

Gross pathology and histopathology

All goats given glyphosate and one randomly selected goat from each control group were subjected to post-mortem examination at the end of the post-treatment observation period (days 14-15). All surviving goats to be necropsied were killed by the intravenous administration of a commercial euthanasia solution (T-61, National Laboratories Corp., Somerville, NJ 08876).

Specimens of heart, liver, kidney and spleen were collected from all necropsied animals for histopathological examination. Additional specimens were collected when grossly visible lesions were observed. Slides for histologic examination were prepared from heart, liver, kidney, spleen and other tissues with grossly visible lesions from all animals given glyphosate at 4620 and 3090 mg/kg body weight, and from each of the four untreated control goats that were sacrificed. Tissues were fixed in neutral buffered 10 % formalin and embedded in paraffin. Sections were stained with haematoxylin and eosin and examined microscopically.

Statistics

The LD_{50} was calculate by the moving average method. Group median, minimum and maximum values were calculated for each post-treatment sampling time for all clinical biochemical and haematological parameters. Control values (principals with concurrent vehicle controls) plus all post-treatment values from the concurrent vehicle control goats and calculating for this pool the following statistics: median, minimum value, maximum value, 5^{th} quantile, and 95^{th} quantile. Study-wide minimum and maximum control values were obtained by pooling control data from all 4 dose levels. Medians for post-treatment determinations that fell above or below the 95^{th} or 5^{th} quantiles respectively were considered significantly greater or less than the control median ($P < 0.05$). Single values for individual animals were considered to have changed significantly if they fell outside the absolute range of control values. The Mann-Whitney test was used for comparison of median percent change in body weight between goats that received glyphosate and their concurrent controls.

II. RESULTS AND DISCUSSION

A. MORTALITY, SURVIVAL TIME, AND LD_{50}

All animals treated with 10000 and 4620 mg/kg bw glyphosate died. 1/5 animals treated with 3090 mg/kg bw also died. The median lethal dose (LD_{50}) was calculated to be LD_{50}, goat, oral = 3530 mg/kg bw. The mortality, survival times and median LD_{50} are given in the table below.

Table 5.8.2-32: The acute toxicity of glyphosate in female goats ([redacted] 1987): Mortality, survival time and median[1] LD_{50} in female goats

Group No. (N=5)	Glyphosate dose (mg/kg bw)	Mortality rate (%)	Survival time (hours)		
			Mean	Min.	Max.
13	10000	100	13.7	3.9	19.2
15	4650	100	16.5	2.4	32.2
16	3090	20	-	71.7	71.7
14	1980	0	-	-	-
LD_{50} = 3530 (2950-4220)[2] mg/kg bw					

[1] Glyphosate doses of 4820 and 7520 mg/kg bw were used in calculating the LD_{50} with the assumption that the mortality for both these levels would be the same as at 4620 mg/kg bw (100 %)
[2] 95 % confidence limits for LD_{50}

B. CLINICAL OBSERVATIONS

One control goat gave birth to a single live kid approximately one hour before the time of treatment. Another control goat gave birth to one normal and one small and very weak kid on day 4 of the experiment. One goat of the 4620 mg/kg bw-treated animals gave birth to two full-term kids during the night before dosing. Abnormal clinical signs observed across all treatment groups are tabulated below.

Table 5.8.2-33: The acute toxicity of glyphosate in female goats ([redacted] 1987): Clinical findings in female goats

Group No.	Dose (mg/kg bw)	Observations
13	10000	CFA (5)[1], apparent colic (2), depressed demeanour (2), slight ataxia (3), recumbency (4), death (5)
15	4620	CFA (5), apparent colic (2), depressed demeanour (2), ataxia (2), laboured breathing (2), recumbency (4), diarrhoea (1), death (5)
16	3090	Animal that died (1): CFA, diarrhoea, apparent colic, subdued demeanour, thirst, ataxia, recumbency, nystagmus, death All surviving animals: DFC (4), apparent colic (2) and diarrhea (4)
14	1980	DFC (5), diarrhoea (3)

[1] Number of goats affected; CFA = cessation of feeding activity; DFC = decreased feed consumption

C. BODY WEIGHT CHANGES

Immediately prior to death most animals exhibited a loss in body weight. Of the animals that survived until terminal sacrifice, those in the 3090 mg/kg bw group had mean body weights significantly less than their respective control group. Control animals and goats in the 1980 mg/kg bw group had similar mean body weights. The feed consumption was not measured, but cessation of feeding activity was observed in all treatment groups.

Table 5.8.2-34: The acute toxicity of glyphosate in female goats ([redacted] 1987): Body weight changes in female goats

Glyphosate dose (mg/kg bw)	Post-treatment day weighted	Number of goats weighed	Percent change from initial weight		
			Median	Minimum	Maximum
Goats weighed immediately prior to death					
10000 - 4620	0	6[1]	-1.8	-3.9	3.8
4620	1	1	0	0	0
3090	3	1	-8.2	-8.2	-8.2
Surviving goats weighed at scheduled times					
3090	7	4	-12.7[3]	-18.1	-5.1
Control	7	4[2]	4.7	0	19.3
3090	14	4	-4.7	-14.7	7.0
Control	14	4[2]	-2.7	-6.6	14.8
1980	7	5	-6.9	-11.7	-3.7
Control	7	5	-2.8	-13.3	1.6

Control = concurrent control goats for preceding group

D. POST-MORTEM GROSS PATHOLOGICAL OBSERVATIONS

No gross lesions that could be attributed to treatment were seen.
All results of the post-mortem gross pathology observations are tabulated below.

Table 5.8.2-35: The acute toxicity of glyphosate in female goats ([redacted] 1987): Summary of gross pathological findings in treated and control goats

Dose (mg/kg bw)	D/S	Body as a whole	Respiratory	Cardio-vascular	Haemic and lymphatic	Gastro-intestinal	Urogenital
10000	5/0	NGPD	Pulmonary oedema (4/5)[1] Pneumonia (1/5)	NGPD	NGPD	NGPD	NGPD
4620	5/0	Serous atrophy of fat (1/5)	Pulmonary oedema (4/5)	NGPD	NGPD	Hepatic atrophy (1/5)	Macerated foetus (1/5)
3090	1/4	Serous atrophy of fat (1/5)	Pneumonia (1/5)	Pericarditis (1/5)	NGPD	Fatty liver (1/5) Rumen haemorrhage (1/5)	Pallor, kidneys (4/5) Renal hypertrophy (1/5) Endometritis (2/5) Foetal Death (1/5)
1980	0/5	NGPD	Pulmonary oedema (3/5) Pneumonia (1/5)	NGPD	NGPD	Fatty liver (1/5) Chronic hepatitis (1/5)	Renal atrophy (1/5)
Controls[2]	0/4	Minimal fat stores (1/4)	Pulmonary oedema (2/4)	NGPD	NGPD	NGPD	Pallor, kidneys (2/4) Cystitis (1/4) Metritis (1/4) Endometritis (1/4)

D/S = Died/Sacrificed; NGPD = No gross pathological diagnosis; (number of animlas with finding /number of animals)
[1] Animal affected/total animals in group
[2] only one randomly selected goat from each of the 4 control groups subjected to post mortem examination

E. HISTOPATHOLOGICAL OBSERVATIONS

Histological examination was performed only on heart, liver, kidney, spleen and other tissues with grossly visible lesions from animals given glyphosate at 4620 and 3090 mg/kg bw and of 4 sacrificed control animals. The most consistent finding in animals that died during the observation period was mild to severe tubular nephrosis. 3090 mg/kg bw-treated animals that survived lacked such lesions. 4/5 goats that died during the observation period had mild fatty change in the liver.

Table 5.8.2-36: The acute toxicity of glyphosate in female goats ([redacted] 1987): Major histopathological diagnoses in selected female goats given glyphosate and control goats

Dose (mg/kg bw)	Group No.	Goat No.	Control for Group Number	Organ or Organ System

[1] Fatally poisoned goats; all other goats shown were euthanized at the end of the study
NMD = No Morphologic Diagnosis.
N/A = Organ or system not examined histologically.

F. CLINICAL BIOCHEMISTRY AND HAEMATOLOGY

Elevation of blood urea nitrogen concentration, serum creatinine concentration, and numbers of circulating segmental neutrophils were the most consistent laboratory findings in goats given glyphosate. These changes were observed at all dose levels used in this study.

Clinical laboratory findings were almost universally within or near reference range for surviving glyphosate-treated goats at the end of the experiment (day 14).

Biochemical and haematological measurements, where one or more values fall outside of reference range, are tabulated below.

Table 5.8.2-37: The acute toxicity of glyphosate in female goats ([redacted] 1987): Blood parameter findings in goats

Paramter (unit)	Ref. value*	Control[1]	Death in <4 h (1 goat)[2]	Death in 15-20 h (3 goats)[3]	Death in 32-72 h (2 goats)[4]	Death in 72 h (1 goat)[5]	Sign of intoxication observed (4 goats)[6]		No signs of intoxication observed (5 goats)[7]

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Four groups consisting of five female (Spanish) goats obtained from farms were administered single oral gavage doses of glyphosate (via stomach tube) at doses of 1980, 3090, 4620, and 10000 mg/kg bw. Water was used as a vehicle in four negative control groups of five goats each. Mortality, clinical signs, body weight, haematology, clinical biochemistry, gross necropsy, histopathology were assessed during

a post-treatment observation period of 14 days.

At least three goats included in this study were discovered to be pregnant and, thus, females of different hormonal and physiological status were used. Weight and age of the test animals were widely distributed. Although randomization was applied with regard to weight, the test population was quite heterogeneous. Due to the small number of animals investigated, the relevance of the biochemical and haematological findings is questionable.

The acute oral LD_{50} was calculated to be 3530 mg/kg bw.

The study is considered acceptable in spite of the heterogeneity of the animals used. It must be taken into account that studies of this type are usually not required in Europe for active ingredients in plant protection products and that no guideline exists. The quality of the study is suitable to provide additional information about acute oral toxicity in a ruminant species. The maximum dose exceeded those used in acute toxicity studies in laboratory rodents and more parameter were assessed in this study than would be included in an acute oral toxicity study in rodents. However, pathology was confined to four of a total of 20 control animals. In addition, sometimes data obtained in the four control groups were pooled and sometimes reported separately. The acute oral toxicity of glyphosate in goats was low.

Assessment and conclusion by RMS:

CA 5.8.2/009

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	1987
Report title	The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats
Report No	80007[redacted]
Document No	[redacted]-80-451
Guidelines followed in study	None stated
Deviations from current test guideline	Not applicable, non-guideline study
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes.
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

MON-0139, an aqueous formulation containing glyphosate isopropylamine salt (62.5 %) was administered as a single dose via stomach tube to five groups (N=5) of female Spanish goats at doses of 10000, 6700, 5360, 4290, or 1400 mg/kg bw. Mortality, clinical signs, body weight, haematology, clinical biochemistry, gross necropsy, and histopathology were observed for a post-treatment period of 14 days. Clinical signs, haematology, clinical biochemistry, and pathology were investigated in an effort to identify changes that are characteristic of MON-0139 intoxication and could be useful for diagnostic purposes.

The median acute oral LD_{50} was found to be 5700 mg/kg bw and the minimum lethal dosage (MLD) was 4290 mg/kg bw. The minimum dosage producing definite signs of illness (reduced feed consumption, diarrhoea) was 4290 mg/kg bw. Signs of toxicity in goats that died during the observation period included decreased feed consumption, abdominal distress, ataxia and, shortly prior to death, recumbency. One goat that died and one surviving goat each displayed an unusual "collapsing syndrome" of apparent neurological origin approximately 2 days after receiving MON-0139, while other goats displayed various other neurological signs. Sign of toxicity in goats that were sacrificed according to schedule included decreased feed consumption, diarrhoea, and loss of bodyweight. One goat developed extensive ulceration of the tongue and oral mucosa. These lesions healed completely by the end of the 14-day observation period.

No lesions considered to be treatment-related were noted at gross necropsy. No pathognomonic lesions were seen microscopically in treated goats. Mild to severe tubular nephrosis was the only consistent histopathological lesion observed in treatmentgoats died; however, this lesion was not observed in treatment goats that lived until the end of the experiment (days 14-15). This lesion is considered to be diagnostically significant for goats that die a few days after an appropriate level of exposure. Ischemic hippocampal neurons were observed in the brain of one goat that had displayed the so called "collapsing syndrome".

Changes in clinical biochemical parameters associated with toxicity included moderate elevation of serum urea nitrogen (BUN) and mild to moderate elevation of serum creatinine (SC). Slight elevations in serum glutamic oxaloacetic transaminase (SGOT) and lactic dehydrogenase (LDH) activity were also observed in terminal animals immediately prior to death. Temporary reductions in K and LDH were the only apparent treatment-related responses in goats dosed at 1400 mg/kg bw. No other diagnostically or toxicologically significant changes were observed. None of the biochemical parameters measured appeared to be involved in, or indicate the cause of, the unusual neurological manifestations seen in some goats receiving MON-0139.

Changes in circulating leukocytes associated with treatment with MON-0139 involved an increase in absolute numbers of mature (SEGS) and immature (BANDS) neutrophils with a decline in numbers of basophils and eosinophils. No consistent treatment-related changes in erythrocyte parameters were observed in this study.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:	MON-0139
Identification:	N-(phosphonomethyl)glycine isopropylamine salt
Description:	Amber liquid
Lot/Batch #:	LURT 08020
Purity:	62.5 % (46.2 % for glyphosate)
Stability of test compound:	Stable for >1 year at 29.5 ºC. Store in a cool, dry area at 18.3-29.5 ºC

Vehicle:	Water was used to dilute the test article (1:1) and to wash any residue from the container holding the dose and from the stomach tube. The total volume of water was approximately 500 mL/goat.
Test animals:	
Species:	Goat
Strain:	Spanish[1]
Source:	[redacted]
Age:	8 months to 4 years
Number/Sex:	45 females
Weight at dosing:	14.7- 47.0 kg
Acclimation period:	At least 30 days
Diet/Feed:	During acclimatisation: bermuda grass hay and a commercial goat meal containing not less than 16.0 % crude protein (Purina Goat Chow Coarse). After dosing: bermuda grass hay
Water:	Fresh water and mineral salt blocks available at all times
Housing:	During acclimatisation: Outdoor covered pens After dosing: Indoor pens
Environmental conditions:	Not reported

[1]The term Spanish is used to distinguish range meat goats from Angoras and dairy breeds. Most are of the same origin as the Mexican Criollo but they may show traces of Nubian and Toggenburg blood.

B. STUDY DESIGN AND METHODS

Animal assignment and treatment:
Groups of five of female Spanish goats received the test item, MON-0139, at dose levels of 10000, 6700, 5360, 4290, and 1400 mg/kg bw by oral gavage (rumen intubation) in a sequential manner. Initially, the test item was given at 10000 mg/kg/bw and subsequent doses were selected based on the observed responses. Four groups of negative control consisted of five animals each. They were concurrently treated with the vehicle (tap water). All goats were penned by treatment group and observed daily during pre-treatment and at least twice daily following treatment. Surviving animals were observed for 14–15 days after treatment. Blood samples were collected on three separate days during pre-treatment and 1, 3, 7, and 14 days after dosing (designated as day 0). Additional samples were then taken at unscheduled times when dictated by clinical signs or evidence of impending death.
During the initial holding period, all goats were vaccinated for enterotoxaemia, treated for internal parasites and observed for signs of disease. Only goats without visible evidence of active disease and weighing more than 13 kg,

Randomization
All goats available for experimental use were ranked according to increasing bodyweight - The resulting ranking was divided into 5 nearly equal groups. Treatment and control groups of 5 goats each were formed by randomly selecting 1 goat from each of the 5 divisions of the ranking in order that the resulting groups would be representative with respect to bodyweight of the pool from which they were selected.

Body weight
Body weights were determined prior to dosing and for surviving animals on post-dosing days 7 and 14.

Clinical Biochemistry
An atomic absorption spectrophotometer (Perkin Elmer Model 403, Perkin-Elmer Corp.) was used to

determine serum levels of calcium, magnesium, potassium, and sodium, as outlined in the manufacturer's manual. Serum levels of glucose, urea nitrogen, total protein (TP), alkaline phosphatase, lactic dehydrogenase, and glutamic oxaloacetic transaminase were determined on automated equipment (Gilford model 3500 computer directed analyser, Gilford Instruments, Inc.) according to manufacturer's procedures. Four other serum components were determined with the same automated equipment; however, different procedures and reagents were used for. these determinations, i.e., inorganic phosphorus (Inorganic Phosphorous Reagent, Worthington Diagnostics), cholinesterase (Reagent Set Kit, Biodynamics/BMC Div), gamma-glutamyl transferase (Reagent Set Kit, Biodynamics/BMC Div.) and creatine phosphokinase (CK-NAC Reagent Set Kit, Biodynamics/BMC Div.). Serum creatinine was determined on automated equipment according to manufacturer's procedures (Technicon Auto Analyser, Technicon Corporation).

Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) and allowed to clot at ambient temperature; the serum was separated by centrifugation. Serum LDH activity, CPK activity, and GLU concentration was determined as soon as possible after sample collection.

Haematology
Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) containing disodium ethylenediamine-tetraacetate. Blood smears for differential leukocyte counts were made immediately from blood containing no anticoagulant and stained with Wright's stain (Hema-Tek Slide Stainer, Ames Company). One hundred leukocytes were classified. Haemoglobin concentration was measured as cyanmethaemoglobin with a haemoglobinometer (Coulter Hemoglobinometer, Coulter Electronics). Erythrocyte count, mean corpuscular volume, haematocrit and total leukocyte count were determined with an electronic particle counter (Coulter Model ZBI with MCV/Hemat Computer and Channelyzer). Mean corpuscular haemoglobin and mean corpuscular haemoglobin concentration values were calculated.

Pathology
All goats given MON-0139 and one randomly selected goat from each control group were subjected to post-mortem examination at the end of the post-treatment observation period (days 14-15). All surviving goats to be necropsied were killed by the intravenous administration of a commercial euthanasia solution (T-61 Solution, National Laboratories Corp., USA).
Specimens of heart, liver, kidney, spleen and other tissue with grossly visible lesions were collected only from animals dosed at 6700 and 5360 mg/kg bw, and from each of the four untreated control goats that were sacrificed. Additional specimens were collected from one goat dosed at 4290 mg/kg bw and one goat dosed at 1400 mg/kg bw. Histopathologic examination on animals of the highest dose group were not performed. Tissue sections were stained with haematoxylin and eosin and examined microscopically.

Statistics
The LD_{50} was calculated by the method of Litchfield and Wilcoxon. Group median, minimum and maximum values were calculated for each post-treatment sampling time for all clinical biochemical and haematological parameters. Control values for each treatment groups were obtained by pooling all pre-treatment values (principals with concurrent untreated controls) plus all post-treatment values from the concurrent untreated control goats and calculating for this pool the following statistics: median, minimum value, maximum value, 5^{th} quantile, and 95^{th} quantile. Medians for post-treatment determinations that fell above or below the 95^{th} or 5^{th} quantiles respectively were considered significantly greater or less than the control median ($P<0.05$). Single values for individual animals were considered to have changed significantly if they fell outside the absolute range of control values. Study-wide minimum and maximum control values were obtained by pooling control data from all 5 dose levels. The Mann-Whitney test was used for comparison of median percent change in bodyweight between goats that received MON-0139 and their concurrent controls.

II. RESULTS AND DISCUSSION

A. MORTALITY, SURVIVAL TIME, AND LD_{50}

Treatment with 10000, 6700, 5360, 4290, and 1400 mg/kg bw MON-0139 resulted in 5/5, 3/5, 2/5, 2/5, and 0/5 deaths, respectively. In the four control groups, there were no deaths. The acute oral LD_{50} for the dose-mortality data of this study was 5700 mg/kg bw MON-0139 with confidence limits of 3730 and 8710 mg/kg bw. The mortality and survival times are given in the table below.

Table 5.8.2-38: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted] 1987): Mortality, survival time and median acute oral LD_{50} in female goats given MON-0139

Number of animals	MON-0139 Dosage[1] (mg/kg bw)	Mortality rate (%)	Survival time (hours)		
			Mean	Min.	Max.
5	10000	100	30.6	15.6	42.0
5	6700	60	52.5	37.0	64.0
5	5360	40	48.2	47.5	49.0
5	4290	40	69.2	53.2	85.1
5	1400	0	-	-	-
Lethal dose levels (mg/kg bw)					
LD_{50}= 5700 (confidence limits: 3730-8710) mg/kg bw					
LD_{16} = 2800 mg/kg bw					
LD_{84} = 11000 mg/kg bw					

[1] MON-0139 given as a single oral dose.

B. CLINICAL OBSERVATIONS

Clinical signs of goats that died included decreased feed consumption, abdominal distress, ataxia and, shortly prior to death, recumbency. One goat that died and one surviving goat dosed at 6700 mg/kg bw each displayed an unusual "collapsing syndrome" of apparent neurological origin approximately 2 days after receiving MON-0139 while other goats displayed various other neurological signs. One surviving goat developed extensive ulceration of the tongue and oral mucosa. These lesions healed completely by the end of the 14-day observation period.

Table 5.8.2-39: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted], 1987): Prominent clinical observations in female goats given MON-0139

Number of animals	Dosage (mg/kg bw)	Observations
5	10000	DFC (5)[1], apparent colic (5); ataxia, shaking and jerking movements (2); depression (2); head bobbing (2); nystagmus (1); recumbency (4); diarrhoea (1); paddling (2); mild convulsions (2); death (5)
5	6700	Non-survivors (3): DFC (3); apparent colic (2); diarrhoea (1); bloating (3); ataxia (3); "saw-horse" stance (2); tremor (1); recumbency (3); nystagmus (2); jerky movements (2); blinking (1); terminal clonic-tonic activity (3); death (3) Survivors (2): DFC (2); bloating (1); abdominal distention (1); tremor (2); "collapsing syndrome" (1); diarrhoea (2)[2]
5	5360	Non-survivors (2): DFC (2); diarrhoea (1); ataxia (2); "saw-horse" stance (1); salivation (1); recumbency (1); tremor (l); "star-gazing" trance (l); death (2) Survivors (3): DFC (3); diarrhoea (3)

5	4290	Non-survivors (2): DFC (2); ataxia (1); "collapsing syndrome" (1); "chewing convulsions" (1); recumbency (2); salivation (1); terminal opisthotonus-like convulsions (l); death (2) Survivors (3): DFC (3); diarrhoea (3); apparent colic, salivation, lethargy, ulceration of oral mucosa (1)
5	1400	Minimal or no ill effects seen; reduced urination (?), abdominal distention (2); abortion (l)
20	0	Abortion (1)

DFC = decreased feed consumption
[1] Number of goats affected

C. BODY WEIGHT CHANGES

No statistically significant differences in body weight gain were observed between the groups treated with MON-0139 and their respective control groups. Feed consumption, although not precisely measured, was greatly reduced following treatment with MON-0139 at doses of 4290 mg/kg bw and above. For most groups, feeding activity gradually increased, reaching normal levels by the end of the study.

Table 5.8.2-40: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted] 1987): Body weight changes in goats given MON-0139

Dose level (mg/kg bw)	Post treatment day weighed	Number of goats weighed	Percent change from initial weight

D. POST-MORTEM OBSERVATIONS

No lesions considered to be treatment-related were noted at gross necropsy.

Table 5.8.2-41: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted] 1987): Significant gross pathologic diagnoses in female goats given MON-0139 and sacrificed untreated control goats

Dose level (mg/kg bw)	D/S[1]	Body as a whole	Respiratory	Cardio-vascular	Hemic and lymphatic	Gastro-intestinal	Urogenital
10000	5/0	NGPD[2]	pulmonary oedema (2/5)[3]	NGPD	NGPD	NGPD	NGPD
6700	3/2	NGPD	pulmonary oedema (1/5)	NGPD	NGPD	bloated (2/5)	pale kidneys (1/5) renal hypertrophy (1/5)
5360	2/3	minimal fat stores (1/5)	pulmonary oedema (3/5)	NGPD	NGPD	fatty liver (4/5)	pale kidneys (2/5)
4290	2/3	NGPD	pulmonary oedema (3/5)	NGPD	NGPD	fatty liver (1/5) gallbladder oedema (1/5)	pale kidneys (2/5) renal hypertrophy (1/5)

E. HISTOPATHOLOGICAL OBSERVATIONS IN SELECTED MON-0139 TREATED AND UNTREATED GOAT

Histologic examination was performed only on heart, liver, kidney, spleen and other tissues with grossly visible lesions from animals given MON-0139 at 6700 and 5360 mg/kg bw, and from each of the four untreated control goats that were sacrificed. In addition, histologic examination was performed on tissues from one goat given MON-0139 at 4290 mg/kg and on tissues from one goat given MON-0139 at 1400 mg/kg. The most consistent finding in fatally poisoned animals was mild to severe tubular nephrosis.

Table 5.8.2-42: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted], 1987): Major histopathologic diagnosis in selected female goats given MON-0139 and sacrificed untreated control goats

Dose level (mg/kg bw)	Goat Number	Organ or organ system				
		Heart	Spleen	Liver and Gallbladder	Urogenital	Other

[2] Fatally poisoned
[3] Foetal tissues not examined

F. CLINICAL BIOCHEMISTRY AND HAEMATOLOGY

Slight to moderate elevations in blood urea nitrogen (BUN) and serum creatine concentrations (SC) were observed in all animals that died during the study. These findings may be related to the histopathologic kidney lesions observed in these animals. Slight elevations in serum glutamic oxaloacetic transaminase (GOT) and lactic dehydrogenase (LDH) activity were also observed in terminal animals immediately prior to death.

No other diagnostically or toxicologically significant changes were observed. None of the biochemical parameters measured appeared to be involved in, or indicate the cause of, the unusual neurological manifestations seen in some goats receiving MON-0139. The results are summarized in the following table.

Table 5.8.2-43: The acute oral toxicity of the isopropylamine salt of glyphosate (MON-0139) in female goats ([redacted] 1987): Clinical biochemical and haematological measurements (min-max values) for goats given MON-0139

Study conclusion

The median acute oral LD_{50} was found to be 5700 mg/kg bw. The minimum lethal dose was 4290 mg/kg bw. The minimum dose producing definite signs of illness (reduced feed consumption, diarrhoea) was 4290 mg/kg bw. The lowest dose of MON-0139 given in this study (1400 mg/kg bw) produced minimal or no signs of toxicity. Signs of CNS dysfunction including behavioural abnormalities and convulsion were seen at MON-0139 doses of 4290 mg/kg bw and above.

One day of exposure to correctly treated forage should present no hazard to domestic ruminants with respect to any direct action of MON-0139 on animals consuming it. While MON-0139 did produce diarrhoea and apparent abdominal discomfort, vomiting and abnormally frequent regurgitation were not observed.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:

Five groups consisting of five female (Spanish) goats obtained from farms were administered single oral gavage (via rumen intubation) doses of the isopropylamine salt of glyphosate (MON-0139) at doses of 1400, 4290, 5360, 6700, or 10000 mg/kg bw. Water was used as a vehicle in four negative control groups of five goats each. Mortality, clinical signs, body weight, haematology, clinical biochemistry, gross necropsy, histopathology during a post-treatment observation period of 14 days.

At least three goats included to this study gave birth to kids and two aborted during this study and, thus, females of different hormonal and physiological status were used. Weight and age of the test animals were widely distributed. Although randomization was applied with regard to weight, the test population was quite heterogeneous. Due to the small number of animals investigated, the relevance of the biochemical and haematological findings is questionable.

The study is considered acceptable in spite of the heterogeneity of the animals used. It must be taken into account that studies of this type are usually not required in Europe for active ingredients in plant protection products and that no guideline exists. The quality of the study is good and it is suitable to provide additional information about acute oral toxicity in a ruminant species. The maximum dose exceeded those used in acute toxicity studies in laboratory rodents and more parameters were assessed in this study than would be included in an acute oral toxicity study in rodents. However, pathology was confined to four of a total of 20 control animals. In addition, sometimes data obtained in the four control groups were pooled and sometimes reported separately. The acute oral LD_{50} was found to be 5700 mg/kg bw. The oral acute toxicity of the isopropylamine salt of glyphosate in goats was comparable to the one of glyphosate technical acid when corrected for purity (see also CA 5.8.2/008). The acute oral toxicity for both forms of glyphosate was low in goats.

Assessment and conclusion by RMS:

CA 5.8.2/010

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	1987
Report title	The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle
Report No	80002
Document No	[redacted]-82-003
Guidelines followed in study	None stated
Deviations from current test guideline	Not applicable, non-guideline study
Previous evaluation	Yes, accepted in RAR (2015)
GLP/Officially recognised testing facilities	Yes.
Acceptability/Reliability:	Supportive
Category study in AIR 5 dossier (L docs)	Category 2a

2. Full summary

MON-0139, an aqueous formulation containing glyphosate isopropylamine salt (62.4 %) was administered in seven consecutive daily doses by stomach tube to Brahman cross heifers. In a preliminary trial, MON-0139 was administered at a dose of 1000 mg/kg bw/day to two heifers. Based upon the observed response at that dose, subsequent doses of 540, 830, 1290 and 2000 mg/kg bw/day were administered to groups of three heifers each. Concurrent negative control animals (n=2 per treatment group) were treated with the

vehicle only. Mortality, clinical signs, body weight, haematology, clinical biochemistry, gross necropsy, and histopathology were observed for a post-treatment period of 14 days.

All three top dose heifers died within 1.5 days after receiving the sixth or seventh dose. In these animals, nervous system effects like head tremors, convulsions, ataxia and possible visual impairment and shortly prior to death, sternal recumbency occurred. In the group receiving 1290 mg/kg bw/day, one heifer also died after the final dose but without exhibiting signs of nervous dysfunction. Clinical signs of general toxicity included a decrease in feed intake, weight loss, diarrhoea and behavioural depression, and were noted at the two upper dose levels. Diarrhoea and decreased feed consumption were also seen in the mid dose group receiving 830 mg/kg bw/day.

The minimum lethal dose (MLD), minimum toxic dose (MTD) and no observable effect level (NOEL) were estimated to be 1290, 830, and 540 mg MON-0139/kg bw/day, respectively.

Gross pathology revealed signs of dehydration and of gastrointestinal irritation at the upper dosages (mucosal congestion of the rumen, abomasum and duodenum and erosions of the mucosa of the abomasum). High kidney weight to brain weight ratios were seen in all heifers given MON-0139 at 2000 mg/kg bw/day and two of three heifers given MON-0139 at 1290 mg/kg bw/day. High liver weight to brain weight ratios were observed in all heifers given MON-0139 at 2000 mg/kg bw/day.

Histopathologic examination was performed only on liver, kidney, and other organs with gross lesions from heifers given MON-0139 at 1290 and 830 mg/kg bw/day. Histopathological findings were confined to the kidneys and consisted of mild to marked tubular vacuolization (primarily proximal convoluted tubules) and nuclear pyknosis in many tubular epithelial cells in the heifers receiving 1290 mg/kg bw/day. No lesion was seen microscopically in liver from these heifers. Renal tubular vacuolization was not observed in heifers given MON-0139 at 830 mg/kg bw/day.

Clinical laboratory findings associated with MON-0139 doses of 1290 and 2000 mg/kg bw/day consisted of haemoconcentration (elevated PCV, HGB, RBC, and STP); increased serum levels of urea nitrogen, creatinine, GOT, LDH, CK and reduced number of circulating lymphocytes and eosinophils. In addition, heifers that died during the study period exhibited increased numbers of circulating immature (BANDSA) and mature (SEGSA) neutrophils. The surviving heifers (1290 or 830 mg MON-0139/kg bw/day) exhibited mild reductions in serum levels of sodium, inorganic phosphorus, and serum cholinesterase activity. Significant elevation of median serum magnesium concentration was observed at MON-0139 doses above 540 mg/kg bw/day. Significant reduction of median serum potassium (K) concentration was seen at all levels of MON-0139 exposure; however, the decline in K for heifers given MON-0139 at the lowest dose level (540 mg/kg bw/day) was small in magnitude and values for K remained within the limits of study-wide control values for all individuals of this group.

I. MATERIALS AND METHODS

A. MATERIALS

Non-labelled test material:	MON-0139
Identification:	N-(phosphonomethyl)glycine isopropylamine salt
Physical state:	Aqueous solution
Description:	Amber liquid
Lot/Batch #:	LBRT 08023
Source:	Monsanto Company, St. Louis, MO
Purity:	62.4 % (46.2 % for glyphosate N-(phosphonomethyl)glycine)

Stability of test compound:	Stable for >1 year at 29.5 ºC. Store in a cool, dry area at 18.3-29.5 ºC
Vehicle:	Water (approximately 500 mL/heifer)
Test animals:	
Species:	Cattle
Strain:	Brahman cross
Source:	[redacted]
Age:	Not reported (heifers)
Number/Sex:	20 females
Weight at dosing:	169 to 248 kg (mean 215.6 ± 23.1 kg)
Acclimation period:	At least 30 days
Diet/Feed:	During acclimatisation: bermudagrass hay and a commercial feed concentrate containing not less than 13.0 % crude protein (Purina Commercial Creep Chow) After acclimatisation: bermudagrass hay
Water:	Tap water, *ad libitum*
Housing:	During acclimatisation: Outdoor pens for a period of 15 to 19 days then indoor pens for a period of 11 to 15 days. After dosing: Individual indoor pens.
Environmental conditions:	Not reported
Concomitant treatment:	During the initial holding period, all heifers were vaccinated for Clostridial and Leptospiral diseases and treated for internal parasites.

B. STUDY DESIGN AND METHODS

Study dates: 02-Feb-1982 to 05-May-1982

Randomization
All heifers available for experimental use were ranked according to increasing bodyweight. The resulting ranking was divided into 3 nearly equal groups. Treatment groups of three heifers each and control groups of two heifers each were formed by randomly selecting one heifer from each of the three divisions of the ranking in order that the resulting groups would have body weights representative of the pool from which they were selected.

Animal assignment and treatment
Brahman-cross heifers were treated in a sequential manner with MON-0139 by rumen intubation as seven consecutive daily doses of 540, 830, 1000 (preliminary trial, n = 2), 1290, and 2000 mg/kg bw/day (n = 3/group). In the preliminary trial two heifers treated at 1000 mg/kg bw/day over seven consecutive days, body weighing and visual assessment of clinical condition were the only assessments performed.
The test article was given as grams of total formulation per kg body weight. Water was used to dilute the test article (1:1) and to wash any residue from the container holding the dose and from the stomach tube. The total volume of water used for these procedures was approximately 500 mL/heifer. Initially, the test item was given at 2000 mg/kg/bw/day and subsequent doses were selected based on the observed responses. Negative control animals were sham treated with tap water. All animals were penned by treatment group and observed daily during pre-treatment and at least twice daily following treatment. Surviving animals were observed for 14–15 days after treatment until end of study (day 21). Hay consumption was evaluated subjectively by observing feeding activity and visual inspection of the quantity of hay uneaten each day.

Body weight
Body weights were determined prior to dosing (day 0) and on days 6, 14, and 21. Carcass weights were determined for heifers that died during the study period.

Collection of Blood Samples
Samples of blood for clinical biochemical and haematological examination were collected on three separate days during the pre-treatment period. After the first dose of MON-0139 (day 0) samples were collected on days 2, 6, 8, 14 and 21. Samples were taken at unscheduled times when dictated by clinical signs or impending death.

Clinical Biochemistry
An atomic absorption spectrophotometer (Perkin Elmer Model 403, Perkin-Elmer Corp.) was used to determine serum levels of calcium, magnesium, potassium, and sodium, as outlined in the manufacturer's manual. Serum levels of glucose (GLU), urea nitrogen, total protein (TP), alkaline phosphatase, lactic dehydrogenase (LDH), and glutamic oxaloacetic transaminase were determined on automated equipment (Gilford model 3500 computer directed analyser, Gilford Instruments, Inc.) according to manufacturer's procedures. Four other serum components were determined with the same automated equipment; however, different procedures and reagents were used for these determinations, i.e., inorganic phosphorus (Inorganic Phosphorous Reagent, Worthington Diagnostics), cholinesterase and gamma-glutamyl transferase (Reagent Set Kit, Biodynamics/BMC Div.), and creatine phosphokinase (CK-NAC Reagent Set Kit, Biodynamics/BMC Div). Serum creatinine was determined on automated equipment according to manufacturer's procedures (Technicon Auto Analyser, Technicon Corporation).

Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) and allowed to clot at ambient temperature; the serum was separated by centrifugation. Serum LDH activity, CPK activity, and GLU concentration was determined as soon as possible after sample collection.

Haematology
Blood was collected from the external jugular vein into evacuated glass tubes (Vacutainer tubes, Becton) containing disodium ethylenediamine-tetraacetate. Blood smears for differential leukocyte counts were made immediately from blood containing no anticoagulant and stained with Wright's stain (Hema-Tek Slide Stainer, Ames Company). One hundred leukocytes were classified. Haemoglobin concentration was measured as cyanmethemoglobin with a hemoglobinometer (Coulter Hemoglobinometer, Coulter Electronics). Erythrocyte count, mean corpuscular volume, haematocrit and total leukocyte count were determined with an electronic particle counter (Coulter Model ZBI with MCV/Hemat Computer and Channelyzer). Mean corpuscular haemoglobin and mean corpuscular haemoglobin concentration values were calculated.

Pathology
Except for the two heifers of the preliminary trial, all animals given MON-0139 and both heifers from each control group were subjected to post-mortem examination at the end of the post-treatment observation period. Surviving MON-0139 treated and control heifers to be necropsied were killed by the intravenous administration of a commercial euthanasia solution (T-61 Solution, National Laboratories Corp., USA). Organ weight was measured for kidney, liver, and brain. Specimens of heart, liver, kidney, spleen, and other tissues with gross lesions were collected and fixed in neutral, buffered 10 % formalin; however, slides for histologic study were prepared and examined only for liver, kidney and other tissues with gross lesions from animals given MON-0139 at 1290 and 830 mg/kg bw/day, and from six of the eight untreated control heifers. Tissues to be examined microscopically were embedded in paraffin, sectioned, and stained with haematoxylin and eosin.

Statistics
The MTD (minimum toxic dosage) and MLD (minimum lethal dosage) were estimated directly from the morbidity-mortality data. Group median, minimum and maximum values were calculated for each post-

treatment sampling time for all clinical biochemical and haematological parameters. Control values for each treatment group were obtained by pooling all pre-treatment values (principals with concurrent untreated controls) plus all post-treatment values from the concurrent untreated control heifers and calculating for this pool the following statistics: median, minimum value, maximum value, 5th quantile, and 95th quantile. Medians for post-treatment determinations that fell above or below the 95th or 5th quantiles respectively were considered significantly greater or less than the control median ($p \leq 0.05$). Study-wide minimum and maximum control values were obtained by pooling control data from all four dose levels. Single values for individual animals were considered to have changed significantly if they fell outside the absolute range of control values. The Mann-Whitney test was used for comparison of mean percentage change in bodyweight, mean kidney to brain weight ratios (KBR) and mean liver to brain weight ratios (LBR) between heifers that received MON-0139 and their concurrent controls.

II. RESULTS AND DISCUSSION

A. MORTALITY, SURVIVAL TIME AND MTD

All 3 animals treated with 2000 mg/kg bw/day MON-0139 and 1/3 treated with 1290 mg/kg bw/day died.

Table 5.8.2-44: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted], 1987): Survival times, morbidity and mortality

Dose (mg/kg bw/day)	Animal number	Number of doses given	Toxic signs	Death	Survival time[1] (days)	Morbidity (%)	Mortality (%)
2000	41	6	Yes	Yes	6.2	100	100
	45	7			6.5		
	31	7			7.5		
1290	44	7	Yes	Yes	7.5	100	33.3
	40			No	-		
	35						
1000 (preliminary trial)	13	7	Yes	No	-	100	0
	17						
830	37	7	Yes	No	-	100	0
	38						
	39						
540	32	7	No	No	-	0	0
	33						
	42						

No mortality occurred in the eight control animals

B. CLINICAL OBSERVATIONS

In the preliminary study, treatment with 1000 mg/kg bw/day MON-0139 decreased feed intake and induced diarrhoea by the second day of treatment which continued throughout the seven day treatment period. The signs had ceased by the end of the study on day 14.

In the main study, treatment with 2000, 1290, and 830 mg/kg bw/day induced diarrhoea. Animals exposed to 2000 mg/kg bw/day MON-0139 additionally showed nervous system effects including head tremors, convulsions, ataxia, and possible visual impairment and sternal recumbency.

All eight negative control heifers in this study appeared healthy throughout the pre-treatment, treatment and post-treatment periods; no sign of illness was observed.

Table 5.8.2-45: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted], 1987): Prominent clinical observations in heifers given seven daily doses of MON-0139

Number of animals	Dose (mg/kg bw/day)	Observations
3	2000	diarrhoea (3)[1], decreased feed intake (3), nasal discharge (3), foamy salivation (1), head tremors (3), belligerency (1), whole-body tremors (3), ataxia (3), head pressing (1), kicking at imaginary objects (1), apparent visual impairment (1), convulsions (1), falling (1), depression (1), recumbency (3), increased respiratory effort (2), death (3)
3	1290	diarrhoea (3) , decreased feed intake (3), depression (3), weakness (2), death (1)
2 Preliminary trial	1000	diarrhoea (2), decreased feed intake (2)
3	830	diarrhoea (3), decreased feed intake (3)
3	540	no signs of toxicity
8	0	no signs of toxicity

[1] Number of animals affected

C. BODY WEIGHT CHANGES AND FEED CONSUMPTION

Treated animals showed decreased body weight and feed intake (the feed intake was not accurately measured). In the preliminary study, treatment with 1000 mg/kg bw/day MON-0139 decreased feed intake. Treatment with 2000 and 1290 mg/kg bw/day decreased feed intake. Treatment with 1290 mg/kg bw/day induced severe weight loss and depression for the first two weeks. While feed consumption and faecal consistency was similar to that of the controls during the third week after treatment, the animals remained thin and weakened. For the control animals, feed intake and character of the faeces remained normal throughout the study.

Table 5.8.2-46: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted] 1987): Mean percent body weight changes in heifers given MON-0139

Dose (mg/kg bw/day)	Day of treatment	Mean Percentage change from initial body weight (N)			
		MON-0139 treated heifers		Control heifers

D. POST-MORTEM OBSERVATIONS

Few significant gross lesions were noted in heifers that died during the study period; however, at the time of necropsy each was judged to be dehydrated or to have suffered loss of body weight. Nonspecific (agonal)

lesions included aspiration of rumen contents, petechial haemorrhage associated with the epicardium and spleen and pulmonary oedema. Post-mortem evidence of diarrhoea was observed in three of these heifers and no faeces were present in the rectum of a fourth heifer. Other lesions observed in these animals potentially attributable to treatment included erosions of the abomasal mucosa and congestion of the mucosa of the rumen, abomasum, and duodenum. One heifer administered 2000 mg/kg bw/day exhibited hyphaema (blood in the anterior chamber) in both eyes. No treatment-related lesions were observed at necropsy in the other eight MON-0139 treated heifers that were sacrificed at the end of the observation period (day 21 or 22). High kidney weight to brain weight ratios were seen in all heifers given MON-0139 at 2000 mg/kg bw/day and two of three heifers given MON-0139 at 1290 mg/kg bw/day. High liver weight to brain weight ratios were observed in all heifers given MON-0139 at 2000 mg/kg bw/day. These observations became rare or absent at lower MON-0139 dose. Mean KBR was greater than but not significantly different from mean KBR of concurrent controls for MON-0139 doses of 2000 and 1290 mg/kg bw/day. Mean KBR was less than but not significantly different from concurrent controls for heifers given MON-0139 at 830 or 540 mg/kg bw/day. Findings for LBR were similar. A mycotic dermititis was observed in many animals of this study, including untreated control heifers. Major gross pathologic findings noted in treated and control heifers are presented in the following table and unless indicated otherwise were judged to be unrelated to treatment and due to common agents such as parasites or the method of killing.

Table 5.8.2-47: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted], 1987): Mean kidney and liver weight divided by brain weight for heifers given MON-0139 and concurrent controls

Dose (mg/kg bw/day)	Number of heifers	Kidney/Brain	Liver/Brain
2000	3	1.86[2]	7.57[2]
0[1]	2	1.25	6.45
1290	3	1.49[2]	5.96
0[1]	2	0.96	4.81
830	3	1.14[2]	5.75
0[1]	2	1.27	6.08
540	3	1.18	6.14
0[1]	2	1.19	5.92

[1] Concurrent controls for preceding MON-0139 treated group
[2] Approaches being significantly different from concurrent control mean (P <0.083)

E. HISTOPATHOLOGICAL OBSERVATIONS

Microscopic examination of kidney from the heifer given MON-0139 at 1290 mg/kg bw/day that died revealed marked renal tubular vacuolization. The proximal portion of the convoluted tubules appeared to be most severely involved. In addition, many tubular epithelial cells contained pyknotic nuclei. Histologic examination of the abomasum revealed multifocal superficial mucosal erosions, which appeared to be of recent development based on the minimal extent of the associated cellular reaction. Segmental congestion of the ileum (noted grossly) was characterized microscopically by focal necrosis and inflammation of the mucosa overlying Peyer's patches that extended superficially into the lymphoid tissue. Bacterial colonization of these areas in the ileum was marked. Blood in the anterior chamber of both eyes of one heifer was confirmed microscopically and was judged to have been the result of trauma.

The two surviving heifers given MON-0139 at 1290 mg/kg bw/day each had mild renal tubular vacuolisation. Focal vasculitis and perivasculitis was noted in the livers of one animal and one control animal and was considered to be the result of parasite migrations.

There were no significant treatment-related microscopic lesions observed in the tissues studied from heifers given MON-0139 at 830 mg/kg bw/day or tissues studied from control heifers. Dermatomycosis consistent with lesions caused by *Trichophyton spp.* was observed in both treated and control animals.

Table 5.8.2-48: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted], 1987): Major gross pathologic findings in heifers given MON-0139 and in untreated control heifers

F. CLINICAL BIOCHEMISTRY AND HAEMATOLOGY

Treatment with 1290 and 2000 mg/kg bw/day MON-0139 increased haematocrit, haemoglobin, red blood cells and increased serum levels of total protein, urea nitrogen (BUN), creatinine and serum glutamic oxaloacetic transaminase (GOT), lactic dehydrogenase (LDH), and creatine phosphokinase (CPK) activities.
The haematologic alterations were considered to be due to haemoconcentration secondary to fluid shifts resulting from diarrhoea.
Elevations in CPK, GOT, and LDH activities were attributed to muscle damage resulting from convulsions and/or prolonged sternal recumbency.
Slight elevations of BUN and creatinine may have been due to decreased renal perfusion produced by dehydration secondary to diarrhoea. However, the presence of histopathological kidney lesions at 1290 mg/kg bw/day and changes in serum electrolyte levels at several doses suggest that these changes may have been partly due to some renal impairment.
An increase in the number of neutrophils and a decrease in the number of lymphocytes observed at 1290 and 2000 mg/kg bw/day probably represented a response to stress-induced release of corticosteroids.

Table 5.8.2-49: The subacute toxicity of the isopropylamine salt of glyphosate (MON-0139) in female cattle ([redacted] 1987): Days after treatment on which median values for clinical laboratory measurements performed on heifers given MON-0139 for 7 days were significantly different from concurrent median control values

Study conclusion

Exposure of Brahman-cross heifers for seven consecutive days to MON-0139 resulted in clinical signs of toxicity at doses of 830 mg/kg bw/day and above which included loss of appetite and diarrhoea. Mortality was observed at 1290 and 2000 mg/kg bw/day only. In addition, nervous system effects consistent with overt acute toxicity and impending death (head tremors, convulsions, ataxia, etc.) were observed at 2000 mg/kg bw/day. Changes in several haematological parameters observed at 1290 mg/kg bw/day and above may have been secondary to fluid and blood volume alterations resulting from the diarrhoea. Serum chemistry changes and histopathologic lesions indicative of renal damage were observed at 1290 mg/kg bw/day. The no-observable-effect level (NOEL) under the conditions of this study was considered to be 540 mg/kg bw/day.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:

An aqueous solution of the isopropylamine salt of glyphosate (MON-0139) was administered on seven consecutive days by ruminal intubation to four groups of three female cattle (heifers) at 0, 540, 830, 1290 and 2000 mg/kg bw/day. Water was used as a vehicle to give a constant dosing volume of 500 mL. Four concurrent negative controls groups of two heifers each were sham treated with water. Mortality, clinical signs, body weight, haematology, clinical biochemistry, gross necropsy, histopathology were assessed during a post-treatment observation period of 14 days.

Clinical signs of toxicity occurred at doses of 830 mg/kg bw/day and above, including loss of appetite and diarrhoea. Mortality occurred at doses of 1290 and 2000 mg/kg bw/day. Nervous system effects (head tremors, convulsions, ataxia, etc.) were observed at 2000 mg/kg bw/day prior to death.

At the two upper dose levels, haematological changes (haemoconcentration) probably resulted from diarrhoea. Serum chemistry changes and histopathologic lesions indicative of renal damage were observed at 1290 mg/kg bw/day. An increase in ASAT, creatine phosphokinase and lactate dehydrogenase activity suggests rather muscle than liver damage since there were no histological liver findings. Muscle damage could result from convulsions or prolonged sternal recumbency. Some further biochemical findings (blood urea nitrogen, creatinine) could be well due to dehydration but, in particular in the presence of histological kidney lesions, might also provide evidence of renal function impairment.

The statistical calculations in this study were based on very small group sizes of three treated and two negative control animals. Histopathology was confined to slides prepared for liver, kidney and tissues with gross lesions obtained from animals receiving doses of 1290 and 830 mg/kg bw/day and from 6 of the 8 control heifers. Limited data on organ weights was provided as kidney or liver to brain ratios only.

The study is considered acceptable despite the low number of animals per dose group. The quality of the study is suitable to provide additional information about subacute oral toxicity in a ruminant species. The lowest dose of 540 mg/kg bw/day can be considered a NOAEL for toxic effects in this study. Subacute oral toxicity of the isopropylamine salt of glyphosate in young cattle (heifers) was low. Forage application rate for grazing cattle to receive a dose equivalent to the NOAEL is estimated to be 77 pounds per acre (86 kg/ha), an unrealistically high use rate.

2. Full summary

This study evaluated the irritating effect of Roundup® (herbicide consisting of isopropylamine salt of glyphosate at 41 %, surfactant MON-0818 at 15 %, and water) and its ingredients on mucosa of fasted dogs. The irritating effects of Roundup, glyphosate and surfactant on gastric and small intestinal mucosa were tested *in vivo* using Beagle dogs. Histopathological findings were compared with effects caused by 0.25 N hydrochloric acid as positive control agent and with unchanged tissue samples. All test substances were applied directly to mucosae of anaesthetized dogs.

Direct application of Roundup, glyphosate acid, and surfactant caused only mild damage to the stomach and intestine. The severity of the damage was equivalent to that caused by 0.25 N hydrochloric acid. The test materials tended to affect the small intestine more than the stomach. Roundup and its surfactant caused decomposition of the tip of villi in the small intestine. Roundup, glyphosate and surfactant caused oedema and congestion of top mucosal layers and degeneration of epithelium in the stomach.

The oedema and ablation of epithelium were considered to have resulted from interstitial exudation due to congestion-caused microcirculatory disorder. As for the small intestine, in particular, congestion of villi produced oedema in the space between absorptive epithelium and basal membrane, which subsequently pushed up the epithelium to the extent that it might be ablated and detached.

These effects were more severe with the Roundup formulation than with either the IPA salt or the surfactant. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid. Clinical, autopsy and experimental evidence indicate a potential for gastrointestinal damage from glyphosate components of glyphosate formulations, but the frequency of severe injury appears to be low. Irritation was more severe with the Roundup formulation than with either the IPA salt or the surfactant alone. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid.

The IPA salt of glyphosate, Roundup herbicide (41 % IPA) and the surfactant MON-0818 (15 % of which is contained in Roundup) and 0.25 N hydrochloric acid solution (control) were directly administered on the gastric and small intestinal mucosa of fasted male beagle dogs. The specimens were examined microscopically and evaluated for mucosal damage in comparison with normal gastric and intestinal tissues. Direct application of Roundup® herbicide, and the surfactant caused mild mucosal damage in the stomach and intestine. These effects were more severe with the Roundup formulation than. with either the IPA salt or the surfactant. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid. The results suggest that these substances could significantly contribute to the toxicity of glyphosate products.

I. MATERIALS AND METHODS

A. MATERIALS

Test material 1:	Undilute Roundup Formulation
Identification:	41 % isopropylamine (IPA) salt of glyphosate
Lot #:	Oda B6E20 88.10
Purity:	Not reported
Stability of test compound:	Not reported
Test material 2:	Isopropylamine salt of glyphosate
Identification:	Isopropylamine salt of glyphosate (MON139)
Lot#:	LIRT09023
Purity:	63.2 % assay
Stability of test compound:	Not reported
Test material 3:	
Identification:	Undilute Surfactant (MON-0818)
Lot/Batch #:	Not reported
Purity:	Not reported

Stability of test compound:	Not reported
Positive control:	
Identification:	0.25 N hydrochloric acid
Source:	Kokusan Kagaku Co. Ltd.
Purity:	Not reported

Age:	Approximately 15 months
Sex/Number:	Male, one test group consisting of 4to 8 animals
Body weight:	12-15 kg
Acclimation period:	Not reported
Diet/Feed:	DS (Oriental Yeast Co. Ltd.) , *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Stainless steel two-stage cages (Watering System Co.)
Environmental conditions:	Temperature: 23 ± 2 °C Humidity: 55 ± 10 % Air changes: not reported Photocycle: 12 hours light/dark cycle

B. STUDY DESIGN AND METHODS

Administration of test solutions
Roundup was applied undiluted. IPA salt of glyphosate and surfactant were diluted with distilled water to 41 % and 15 % respectively for application. The positive control 6N hydrochloric acid was diluted to 0.25 N solution with distilled water.

Beagle dogs, fasted for a day, were anesthetized with Ketamine and Skisamesonium, and the abdominal incision was performed. The stomach was cut open along the greater curvature with a cautery knife. The anterior wall of the stomach was everted to expose the mucosal tissue. In order to prevent the reflex of bile, etc., cheese cloth was inserted into the oesophagus and the pylorus. Using a silk suture, the gastric mucosa was pulled up to stuff cheese cloth into the serosa side of the posterior wall , thus making two 3cm diameter depressions on the surface of the body of stomach. Into these concavities, the test materials were placed, and left for 30 minutes. Whenever the test material was spilled or reduced in volume for other reasons, a sufficient amount of the test material was added. The small intestine was ligatured at two positions which were 10 cm apart. When doing this, with silk sutures care was taken not to stop blood circulation in the area concerned. A Teflon-coated catheter was inserted into the intestinal duct for administration of test solutions. Each test article was left in the test portion of the intestinal duct for 30 minutes as in the case of the stomach. After the 30-minute application, the stomach was immediately washed with physiological saline and the treatment portion of the stomach was incised for collection. The small intestine was cut open to evert the inner mucosal lining and washed with physiological saline.
The test material-applied portions of stomach and small intestine were fixed with 10 % formalin buffer and their specimens were prepared by a routine method of haematoxylin and eosin stain. These specimens were examined microscopically and evaluated for mucosal damage in comparison with normal gastric and

intestinal tissues.

II. RESULTS AND DISCUSSION

A. HISTOPATHOLOGY OF GASTRIC MUCOSA

The stomach had slight oedema on the mucosa, congestion of the mucosa and very slight degeneration of the epithelium, after Roundup was treated. Application of glyphosate and surfactant also caused similar changes. Glyphosate affected the stomach approximately the same way and to the same degree as Roundup. As for surfactant, congestion of the mucosa was slightly milder than that for Roundup, but other observations were similar. A 0.25 N hydrochloric acid brought the same changes as Roundup, though the oedema and congestion of mucosa were slightly milder than those for Roundup were, while the degeneration of epithelium was slightly more severe.

B. HISTOPATHOLOGY OF SMALL INTESTINE MUCOSA

Roundup caused congestion of villi, oedema of the furthest portion of villi, degeneration and ablation of absorptive epithelium and dilatation of crypts. Glyphosate and surfactant showed the similar changes, though surfactant had slightly milder effect in oedema and glyphosate and surfactant had slightly milder effect in congestion of villi than Roundup. Surfactant did not cause dilatation of crypts, which the other two test materials did. A 0.25 N hydrochloric acid was similar in effect to Roundup, though the severity of the changes brought by the hydrochloric acid was a little higher or similar to that by Roundup.

There was no remarkable change in the mucosa of a normal stomach. The Roundup- treated stomach had slight oedema and congestion of mucosal layers and degeneration of epithelium. There were similar changes in similar severity observed in the stomach treated with glyphosate. Surfactant had slightly milder effect in congestion of mucosa than Roundup , but there were no other differences between surfactant and Roundup as to the changes and their severity. The 0.25 N hydrochloric acid applied stomach displayed damages on mucosa similar to those for Roundup.

There was no remarkable change in a normal intestine. Roundup treatment caused congestion of villi, oedema of villi, degeneration and ablation of epithelium and dilatation and crypts. The glyphosate treated intestine also showed similar changes to the same degree , though its congestion of villi was less severe than that for Roundup. As for surfactant, the same observations except dilatation of crypts were made, but the congestion and oedema of villi were slightly milder than those for Roundup. A 0.25 N hydrochloric acid showed the same changes as Roundup, but the severity of those changes was slightly higher than , or at least the same as that for Roundup. In some cases, decomposition of the tip of villi was observed in the intestines treated with Roundup or surfactant.

n = number of animals

Study conclusion

Roundup, glyphosate and surfactant caused oedema and congestion of top mucosal layers and degeneration of epithelium in the stomach. Treatment of 0.25 N hydrochloric acid also caused the same changes, but the severity was similar to or slightly lower than that by Roundup. As for the intestinal treatment, the three test articles caused congestion of villi, oedema of tips of villi and degeneration and ablation of epithelium. In addition to these, glyphosate and Roundup treated tissues showed dilatation of crypts. A 0.25 N hydrochloric acid also showed the same changes, but the severity of those changes was slightly higher than, or at least the same as that for Roundup. The mucosal damage in the stomach and small intestine caused by treatment of Roundup, glyphosate of surfactant was only mild, equivalent to that caused by 0.25 N hydrochloric acid. The intestine was more severely damaged than the stomach in every case.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:

The 63.2 % concentrate IPA salt of glyphosate, undiluted Roundup herbicide (41 % IPA, 15 % MON-0818 surfactant), the undiluted surfactant MON-0818, and 0.25 N hydrochloric acid solution (control) were directly administered on the gastric and small intestinal mucosa of fasted male beagle dogs. The specimens were examined microscopically and evaluated for mucosal damage in comparison with normal gastric and intestinal tissues. Direct application of Roundup® herbicide, and the surfactant caused mild mucosal damage in the stomach and intestine. These effects were more severe with the

Roundup formulation than with either the IPA salt or the surfactant. The intestine appeared to be more affected than the stomach. The severity of the damage was equivalent to that caused be 0.25 N hydrochloric acid.
The data are considered as supplemental information indicating that highly concentrated glyphosate IPA salt has irritating properties on the stomach and intestine of dogs, nevertheless has a lower impact than the undiluted Roundup herbicide.

1. Information on the study

Data point:	CA 5.8.2
Report author	[redacted]
Report year	1980
Report title	Acute intraperitoneal toxicity of glyphosate in female rat
Report No	Not reported
Document No	Not reported.
Guidelines followed in study	None stated.
Deviations from current test guideline	Not applicable.
Previous evaluation	Not accepted in RAR (2015).
GLP/Officially recognised testing facilities[1,2]	Not specified.
Acceptability/Reliability:	Supportive Route of exposure (intraperitoneal injection); deficiencies in reporting (only limited information on test material, test animals and results available).
Category study in AIR 5 dossier (L docs)	Category 4a

2. Full summary

The test substance, N-phosphono-methyl-glycine, was evaluated for its acute intraperitoneal toxicity potential, by exposing groups of ten Sprague-Dawley strain female rats to doses of 620, 760, 940, 1040 and 1260 mg/kg bw. The test substance was diluted in propylene-glycol in water.
Mortality occurred in the 4 highest dose groups. In the highest dose group (1260 mg/kg bw), 10/10 animals died. In the next lower dose group (1040 mg/kg bw), 8/10 animals died followed by 4/10 and 1/10 deceased animals at 940 mg/kg bw and 760 mg/kg bw, respectively. Transient dyspnoe due to string irritation of viscera was observed. In the deceased animals, superficial liver necrosis, punctiform bleedings of the peritoneum and exudatum between the pleura surfaces were seen. The extent of fibrophosis extending to the viscera was proportional to the time of survival. The late deaths were considered to be caused by

peritonitis instead of test substance-induced toxicity.
The acute intraperitoneal LD_{50} was calculated to be 919 ± 42 mg/kg bw.

I. MATERIALS AND METHODS

A. MATERIALS

Test material:

Identification:	N-phosphono-methyl-glycine
Description:	Not reported
Lot/Batch #:	Not reported
Purity:	Not reported
Stability of test compound:	Not reported
Vehicle and/ or positive control:	Propylene glycol in water/ None

Test animals:

Species:	Rat

Source:	Not reported
Age:	Not reported
Sex:	Females
Weight at dosing:	190 - 210 g
Acclimation period:	Not reported
Diet/Food:	Normal laboratory rodent food (LATI), *ad libitum*
Water:	Tap water, *ad libitum*
Housing:	Not reported
Environmental conditions:	Temperature: 20 ± 2 °C Humidity: 55 - 75 % Air changes: 8/hour Hours light/dark cycle: Not reported

B. STUDY DESIGN AND METHODS

In life dates: Not reported

Animal assignment and treatment:
The dosage of the test substance was 50 % concentration of the test substance in 10 % propylene-glycol in water.
The dose levels are shown in the following table.

Table 5.8.2-52: Acute intraperitoneal toxicity of glyphosate in female rat ([redacted], 1980): Dose levels

Sex	No. of rats	Dose level (mg/kg bw)
Female	10	620
	10	760

	10	940
	10	1040
	10	1260

No details on observations for mortality and clinical signs of toxicity is available.

II. RESULTS AND DISCUSSION

A. MORTALITY
The occurrence of deaths is shown in the following table.

Table 5.8.2-53: Acute intraperitoneal toxicity of glyphosate in female rat ([redacted], 1980): Mortality

Sex	No. of rats	Dose level (mg/kg bw)	Survival time of dead animals (days)	Mortality Dead animals (%)
Female	10	620	all survived	0/10 (0)
	10	760	9	1/10 (10)
	10	940	7-13	4/10 (40)
	10	1040	6-11	8/10 (80)
	10	1260	5-10	10/10 (100)

B. CLINICAL OBSERVATIONS
No test substance related symptoms were observed.
According to the autopsy findings the observed transient limb anemia and the dispnoe were probably due to the strong irritation of viscera caused by the i.p. injection.

C. BODY WEIGHT
No data on body weight available.

D. NECROPSY
In the dead animals, superficial liver necrosis, punctiform bleedings of the peritoneum, exudatum between the pleura surfaces were seen. The extent of fibrophosis extending to the viscera was proportional to the time of survival. The late deaths were considered to be caused by peritonitis instead of test substance induced toxicity.

Study conclusion
The acute intraperitoneal LD_{50} for the test substance N-phosphono-methyl-glycine was calculated to be 919 ± 42 mg/kg.

III. CONCLUSIONS

3. Assessment and conclusion

Assessment and conclusion by applicant:
Acute intraperitoneal toxicity of glyphosate was tested in rats. There is no OECD guideline available for this endpoint. As to be expected, toxicity was higher by this route as compared to oral, dermal or inhalation exposure. Due to the route of exposure and deficiencies in reporting, this study provides only supplementary information. Based on the study results, the acute intraperitoneal LD_{50} is 919 mg/kg bw in female rats.
